THE DICTIONARY OF HUMAN GEOGRAPHY 1
Bibliography 818
Index 957
Preface to the Fifth Edition

Geographical dictionaries have a long history. A number were published in Europe in the seventeenth and eighteenth centuries; a few – mostly those with greater pretensions to providing conceptual order – were described as ‘Geographical Grammars’. The majority were compendia of geographical information, or gazetteers, some of which were truly astonishing in their scope. For example, Lawrence Echard noted with some asperity in his 1691 Compendium of Geography that the geographer was by then more or less required to be ‘an Entomologist, an Astronomer, a Geometrician, a Natural Philosopher, a Husbandman, an Herbalist, a Mechanik, a Physician, a Merchant, an Architect, a Linguist, a Divine, a Politician, one that understands Laws and Military Affairs, an Herald [and] an Historian.’ Margarita Bowen, commenting on 1981 on what she took to be Geography’s isolation from the scientific mainstream in Echard’s time, suggested that ‘the prospect of adding epistemology and the skills of the philosopher’ to such a list might well have precipitated its Cambridge author into the River Cam!

It was in large measure the addition of those skills to the necessary accomplishments of a human geographer that prompted the first edition of The Dictionary of Human Geography. The original idea was John Davey’s, a publisher with an extraordinarily rich and creative sense of the field, and he persuaded Ron Johnston, Derek Gregory, Peter Haggett, David Smith and David Stoddart to edit the first edition (1981). In their Preface they noted that the changes in human geography since the Second World War had generated a ‘linguistic explosion’ within the discipline. Part of the Dictionary’s purpose – then as now – was to provide students and others with a series of frameworks for situating, understanding and interrogating the modern lexicon. The implicit model was something closer to Raymond Williams’ marvellous compilation of Keywords than to any ‘Geographical Grammar’. Certainly the intention was always to provide something more than a collection of annotated reading lists. Individual entries were located within a web of cross-references to other entries, which enabled readers to follow their own paths through the Dictionary, sometimes to encounter unexpected parallels and convergences, sometimes to encounter creative tensions and contradictions. But the major entries were intended to be comprehensible on their own, and many of them not only provided lucid presentations of key issues but also made powerful contributions to subsequent debates.

This sense of The Dictionary of Human Geography as both mirror and goad, as both reflecting and provoking work in our field, has been retained in all subsequent editions. The pace of change within human geography was such that a second edition (1986) was produced only five years after the first, incorporating significant revisions and additions. For the third (1994) and fourth (2000) editions, yet more extensive revisions and additions were made. This fifth edition, fostered by our publisher Justin Vaughan, continues that restless tradition: it has been comprehensively redesigned and rewritten and is a vastly different book from the original. The first edition had over 500 entries written by eighteen contributors; this edition has more than 1000 entries written by 111 contributors. Over 300 entries appear for the first time (many of the most important are noted throughout this Preface), and virtually all the others have been fully revised and reworked. With this edition, we have thus once again been able to chart the emergence of new themes, approaches and concerns within human geography, and to anticipate new avenues of enquiry and new links with other disciplines. The architecture of the Dictionary has also been changed. We have retained the cross-referencing of headwords within each entry and the detailed Index, which together provide invaluable alternatives to the alphabetical ordering of the text, but references are no longer listed at the end of each entry. Instead, they now appear in a consolidated Bibliography at the end of the volume. We took this decision partly to avoid duplication and release space for new and extended entries, but also because we believe the Bibliography represents an important intellectual resource in its own right. It has over 4000 entries, including books, articles and online sources.

Our contributors operated within exacting guidelines, including limits on the length of each entry and the number of references, and they worked to a demanding schedule. The capstone entry for previous editions was ‘human geography’, but in this edition that central place is now
taken by a major entry on ‘geography’, with separate entries on ‘human geography’ and (for the first time) ‘physical geography’. The inclusion of the latter provides a valuable perspective on the multiple ways in which human geography has become involved in interrogations of the biophysical world and – one of Williams’s most complicated keywords – ‘nature’. Accordingly, we have expanded our coverage of environmental geographies and of terms associated with the continued development of actor-network theory and political ecology, and for the first time we have included entries on biogeography, biophilosophy, bioprospecting, bioregionalism, biosecurity, biotechnology, climate, environmental history, environmental racism, environmental security, genetic geographies, the global commons, oceans, tropicallity, urban nature, wetlands and zoos.

The first edition was planned at the height of the critique of spatial science within geography, and for that reason most of the entries were concerned with either analytical methods and formal spatial models or with alternative concepts and approaches drawn from the other social sciences. We have taken new developments in analytical methods into account in subsequent editions, and this one is no exception. We pay particular attention to the continuing stream of innovations in Geographic Information Systems and, notably, the rise of Geographic Information Science, and we have also taken notice of the considerable revival of interest in quantitative methods and modelling: hence we have included for the first time entries on agent-based modelling, Bayesian analysis, digital cartography, epidemiology, e-social science, geo-informatics and software for quantitative analysis, and we have radically revised our coverage of other analytical methods. The vital importance of qualitative methods in human geography has required renewed attention too, including for the first time entries on discourse analysis and visual methods, together with enhanced entries on deconstruction, ethnography, iconography, map reading and qualitative methods. In the previous edition we provided detailed coverage of developments in the social sciences and the humanities, and we have taken this still further in the present edition. Human geographers have continued to be assiduous in unpicking the seams between the social sciences and the humanities, and for the first time we have included entries on social theory, on the humanities, and on philosophy and literature (complementing revised entries on art, film and music), together with crucial junction-terms such as affect, assemblage, cartographic reason, contrapuntal geographies, dialectical image, emotional geography, minor theory, posthumanism, representation and trust (complementing enhanced entries on performance, performativity, non-representational theory and representation). Since the previous edition, the interest in some theoretical formations has declined, and with it the space we have accorded to them; but human geography has continued its close engagement with postcolonialism and post-structuralism, and the new edition incorporates these developments. They involve two continuing and, we think, crucial moments. The first is a keen interest in close and critical reading (surely vital for any dictionary!) and, to repeat what we affirmed in the preface to the previous edition, we are keenly aware of the slipperiness of our geographical ‘keywords’: of the claims they silently make, the privileges they surreptitiously install, and of the wider webs of meaning and practice within which they do their work. It still seems to us that human geographers are moving with considerable critical intelligence in a trans-disciplinary, even post-disciplinary space, and we hope that this edition continues to map and move within this intellectual topography with unprecedented precision and range. The second implication of postcolonialism and post-structuralism is a heightened sensitivity to what we might call the politics of specificity. This does not herald the return of the idiographic under another name, and it certainly does not entail any slackening of interest in theoretical work (we have in fact included an enhanced entry on theory). But it has involved a renewed interest in and commitment to that most traditional of geographical concerns, the variable character of the world in which we live. In one sense, perhaps, this makes the fifth edition more conventionally ‘geographical’ than its predecessors. We have included new entries on the conceptual formation of major geographical divisions and imaginaries, including the globe and continents (with separate entries on Africa, the Americas, Asia, Australasia and Europe), and on Latin America, the Middle East, the global South and the West, and on cognate fields such as area studies and International Relations. But we also asked our contributors to recognize that the world of geography is not limited to the global North. In previous editions, contributors frequently commented on the multiple ways in which modern human geography had worked to privilege and, indeed, normalize ‘the modern’, and together they traced a genealogy of geographical knowledge in which the world beyond Europe and North America was all too often marginalized or produced as a problematic ‘pre-modern’. For this edition, we asked contributors to go beyond the critique of these assumptions and, wherever possible, to
incorporate more cosmopolitan geographies (and we have included a new entry on cosmopolitanism).

And yet we must also recognize that this edition, like its predecessors, remains focused on English-language words, terms and literatures. There are cautionary observations to be made about the power-laden diffusion of English as a ‘global language’, and we know that there are severe limitations to working within a single-language tradition (especially in a field like human geography). The vitality of other geographical traditions should neither be overlooked nor minimized. We certainly do not believe that human geography conducted in English somehow constitutes the canonical version of the discipline, though it would be equally foolish to ignore the powers and privileges it arrogates to itself in the unequal world of the international academy. Neither should one discount the privileges that can be attached to learning other languages, nor minimize the perils of translation: linguistic competences exact their price. But to offer some (limited) protection against an unreflective ethnocentrism, we have been guided by an international Editorial Advisory Board and we have extended our coverage of issues bound up with Anglocentrism and Eurocentrism, colonialism and imperialism, Empire and Orientalism – all of these in the past and in the present – and we continue to engage directly with the politics of ‘race’, racism and violence. All of this makes it impossible to present the works and positions, so that this edition, like its predecessor, reveals considerable diversity and debate within the discipline. We make no secret of the differences – in position, in orientation, in politics – among our contributors. They do not speak with a single voice, and this is not a work of bland or arbitrary systematization produced by a committee. Even so, we are conscious of at least some of its partialities and limitations, and we invite our readers to consider how these other voices might be heard from other positions, other places, and to think about the voices that are – deliberately or unconsciously – silenced or marginalized.

None of these changes is a purely intellectual matter, of course, for they do not take place in a vacuum: the world has changed since the previous edition, and this is reflected in a number of entries that appear here for the first time. Some reach back to recover terms from the recent past that are active in our present – including Cold War, fascism, Holocaust and Second World – but all of them are distinguished by a sense of the historical formation of concepts and the webs of power in which they are implicated. While we do not believe that ‘everything changed’ after the attacks on the World Trade Center and the Pentagon on 11 September 2001, one year after our last edition, a shortlist of terms that have achieved new salience within the field indicates how far human geography has been restructured to accommodate a heightened sensitivity to political violence, including its ethical, economic and ecological dimensions. While many of these terms (like the four we have just mentioned) should have been in previous editions, for the first time we now have entries on: American Empire, asylum, bare life, the camp, ethnic cleansing, spaces of exception, genocide, homo sacer, human rights, intifada, just war, militarism, military geography, military occupation, resource wars, rogue states, security, terrorism, urbicide and war. Human geography has made major contributions to the critical study of economic transformation and globalization too, and our entries continue to recognize major developments in economic geography and political economy, and the lively exchanges between them that seek to explicate dramatic changes in contemporary regimes of capital accumulation and circulation. The global economic crisis broke as this edition was going to press. We had already included new entries on anti-development and anti-globalization, on the International Monetary Fund and the World Social Forum, and on narco-capitalism and petrocapitalism, which speak to some of the ramifications of the crisis, but we also believe that these events have made our expanded critiques of (in particular) capitalism, markets and neo-liberalism more relevant than ever before.

A number of other projects have appeared in the wake of previous editions of the Dictionary: meta-projects such as the International Encyclopedia of Human Geography and several other encyclopedias, an indispensable Feminist Glossary of Human Geography, and a series devoted to Key Concepts in the major subdisciplines of human geography. There is, of course, a lively debate about scale in geography, but we believe that the scale (or perhaps the extent of the conceptual
network) of *The Dictionary of Human Geography* continues to be a crucial resource for anyone who wants to engage with the continued development of the field. It is not the last word – and neither pretends nor wishes to be – but rather an invitation to recover those words that came before, to reflect on their practical consequences, and to contribute to future ‘geo-graphings’. This makes it all the more salutary to return to Echard’s original list and realize that virtually all of the fields he identified as bearing on geography have their counterparts within the contemporary discipline. The single exception is the figure of the Herald, but if this is taken to imply not the skill of heraldry but rather a harbinger of what is to come, then human geography’s interest in prediction and forecasting returns us to the footsteps of our seventeenth-century forebear. Be that as it may, none of us is prepared to forecast the scope and contents of the next edition of *The Dictionary of Human Geography*, which is why working on the project continues to be such a wonderfully creative process.

How to Use This Dictionary

Keywords are listed alphabetically and appear on the page in **bold type**: in most cases, users of the *Dictionary* should begin their searches there. Within each entry, cross-references to other entries are shown in **capital letters** (these include the plural and adjectival versions of many of the terms). Readers may trace other connections through the comprehensive index at the back of the book.

*Suggested readings* are provided at the end of each entry in abbreviated (Harvard) form; a full *Bibliography* is provided between pages 818 and 956, and readers seeking particular references or the works of particular authors should begin their searches there.
Acknowledgements

In the production of this edition, we are again indebted to a large number of people. We are particularly grateful to Justin Vaughan, our publisher at Wiley-Blackwell, for his enthusiasm, support and impeccably restrained goading, and to many others at Wiley-Blackwell (especially Liz Cremona and Tim Beuzeval) who have been involved in the management and implementation of this project. We owe a special debt to Geoffrey Palmer, our copy-editor, who performed marvels turning multiple electronic files into an accurate and coherent printed volume, and to WordCo Indexing Services, Inc., who compiled and cross-checked the Index with meticulous care.

The preparation of a large multi-authored volume such as this is dependent on the cooperation of a large number of colleagues, who accepted our invitation to contribute, our cajoling to produce the entries, our prompts over deadlines and our editorial interventions: we are immensely grateful to them for their care, tolerance and patience. It is with the greatest sadness that we record the deaths of two of them during the preparation of the Dictionary – Denis Cosgrove and Les Hepple – and we dedicate this edition to their memory.

The authors, editors and publishers thank the following for permission to reproduce the copyright material indicated:

Martin Cadwallader for the figure reproduced in the entry for Alonso model from Analytical Urban Geography, 1985.

Blackwell Publishing Ltd with The University of Chicago Press for the figure reproduced in the entry capitalism from D. Harvey, The Limits to Capital, 1982.

Blackwell Publishing Ltd for the figure reproduced in the entry crisis from D. Gregory, Geographical Imaginations, 1993.

University of California Press for the figure reproduced in the entry cultural landscape from Carol O. Sauer, The Morphology of Landscape, 1925. © 1925 The Regents of the University of California.

Peter Haggett for the figure reproduced in the entry for demographic transition from Geography: A Modern Synthesis, 1975.

Peter Haggett for the figure reproduced in the entry for locational analysis, from Locational Analysis in Human Geography, 1977.
ACKNOWLEDGEMENTS

Blackwell Publishing Ltd for figures 1 and 2 reproduced in the entry production of space from D. Gregory, Geographical Imaginations, 1993.

The Estate of Conroy Maddox for the figure reproduced in the entry for reflexivity.

abduction  A form of reasoning that takes accepted knowledge and infers the 'best available' explanations for what is observed. Whereas deduction formally infers the consequences of a cause-and-effect relationship (if $a$, then $b$), and induction infers a conclusion from a number of observations (of the same patterns, for example), abductive reasoning infers relationships from observations rather than asserting them. It thus presents a 'provisional' account for what has been observed (for why $a$ is related to $b$), either inviting further empirical investigation that might sustain the 'explanation' or encouraging deductive work that might put the putative causal chain on a former footing.  

abjection  A psychoanalytic concept that describes a psychic process through which the pure, proper and bounded body and identity emerge by expelling what is deemed impure, horrific or disgusting. The abject refers to bodily by-products such as urine, saliva, sperm, blood, vomit, faeces, hair, nails or skin, but also to impure psychic attachments, such as same-sex desire (Butler, 1997) and to encouraging deductive work that might put the putative causal chain on a former footing. 

aboriginality  A term derived from the Latin ab origine, meaning the original founders, or 'from the beginning'. In the nineteenth century, 'Aborigines' denoted the existing inhabitants of what Europeans called the 'New World'. Today, the terms 'aboriginal peoples' and 'aboriginality' are in official use in Australia and in Canada, and in Canada it is also common to refer to 'First Nations'. Elsewhere, it is more usual to refer to indigenous peoples, and hence indigeneity.

According to the United Nations Working Group on Indigenous Peoples, the interpretation of such expressions should reflect the historical and current situations of these colonized peoples (see colonialism), as well as their manner of self-identification and search for greater degrees of self-determination. However, as a construct of European modernity, 'aboriginality' was freighted with connotations of 'savagery' and lack of culture (Anderson, 2000a) (see also primitivism), and its continued use also obscures the subjectivities of the heterogeneous groups to which it is applied. Indigenous peoples often had no single name to describe themselves before there was a colonizing Other to make this necessary. The Maori (meaning 'ordinary', or 'the people') of New Zealand did not describe themselves as such until they were aware of Pakeha ('not Maori' or Europeans). They knew and named themselves as members of kin-based groups, as is still the case. Likewise, amongst the Kwara’ae of Malaita (one of the Solomon Islands) self-definition is understood in relation to place, genealogy, right of access to land and the right to speak (Gegeo, 2001).

Since the 1980s, globalization and the architecture of neo-liberalism have presented both problems and opportunities. Marginalization and loss of control of resources continue (Stewart-Harawira, 2005), but there is also
potential for insertion into transnational informational and economic networks. This can facilitate steps towards indigenous professionalization and self-determination. Participation in activities such as tourism, oil extraction and cattle ranching by the Cofan and Secoya peoples of the Ecuadorian Amazon has opened spaces for questioning fixed notions of indigenous identities (as ‘natural’ conservationists of remote territories, for example). These are often articulated in different ways and contested within communities, particularly along generational lines (Valdivia, 2005).

Despite official recognition of indigenous peoples in national legislation and constitutional law, the practical implementation of policy remains a problem in many parts of the world. According to the United Nations Working Group in 2003, this applies in areas ranging from rights to land and natural resources to the alleviation of poverty. Institutionalized discrimination is pervasive, not least through superimposed definitions of identity (e.g. for census purposes or for state entitlements). State education systems have often been structured to facilitate integration or assimilation, denying cultural and ethnic diversity. Universities may be complicit. Research on, rather than with, indigenous people is seen as reproducing colonial relations, advancing the career of the researcher rather than indigenous interests. (cf. Smith, 1999b).

**Suggested reading**

Smith (1999); Valdivia (2005).

**abstraction** Methodologically, abstraction involves the conceptual isolation of (a partial aspect of) an object. During the QUANTITATIVE REVOLUTION, abstraction was seen as the starting-point for the construction of spatial models, but few methodological principles were provided (Chorley, 1964). Some critics of SPATIAL SCIENCE were drawn instead to the construction of what the sociologist Max Weber called IDEAL TYPES: ‘one-sided’ idealizations of the world seen from particular points of view. There was nothing especially ‘scientific’ about them, which is presumably why they appealed to the critics, and Weber claimed that this kind of selective structuring is something that we all do all the time. Since it is possible to construct quite different ideal types of the same phenomenon, depending on one’s point of view, the critical moment comes when the ideal type is compared with ‘empirical reality’ – but here too few methodological principles were proposed to conduct or interpret any such comparisons.

**REALISM** rejected both of these approaches as arbitrary and substituted what its proponents saw as a rigorous scientific methodology. According to Sayer (1992 [1984]), abstractions should identify essential characteristics of objects and should be concerned with ‘substantial’ relations of connection rather than merely ‘formal’ relations of similarity (which Chorley (1964) had called ‘analogues’; cf. METAPHOR). Realism turns on identifying those INTERNAL RELATIONS that necessarily enter into the constitution of specific structures. Hence Sayer distinguished a rational abstraction – that is, ‘one that isolates a significant element of the world that has some unity and autonomous force’ – from a chaotic conception – that is, one whose definition is more or less arbitrary. It is no less important to recognize different levels of abstraction, a strategy of considerable importance in theoretical formations such as HISTORICAL MATERIALISM that claim to move between the general and the (historically or geographically) specific (Cox and Mair, 1989). But these prescriptions turn out to be far from straightforward in a HUMAN GEOGRAPHY where ‘context’ cannot be cleanly severed from objects of analysis, and recent debates over SCALE have revealed the importance of revisiting issues of EPistemology and ONtology that are focal to the process of abstraction (Castree, 2005b).

Abstraction is more than a formal method: it is a profoundly human and thoroughly indispensable practice, as Weber recognized, so that what matters are the consequences of particular modes of abstraction. Seen thus, it spirals far beyond the spheres of science and other forms of intellectual enquiry. Many critics have drawn attention to the role of abstraction in the heightened rationalization of everyday life under CAPITALISM – what Habermas (1987b [1981]) called ‘the colonization of the lifeworld’ – and the attendant production of an abstract space, ‘one-sided’ and ‘incomplete’, that Lefebvre (1991b [1974]) identified as the dominant spatial thematic of MODERNITY (see PRODUCTION OF SPACE).

**Suggested reading**

Castree (2005b); Sayer (1982).

**accessibility** The standard definition is the ease with which people can reach desired activity sites, such as those offering employment, shopping, medical care or recreation. Because many geographers and planners believe that access to essential goods and services is an important indicator of QUALITY OF LIFE, measures of access are used to compare the accessibility...
levels of different groups of individuals and households, or of different places or locations. Most measures of accessibility entail counting the number of opportunities or activity sites available within certain travel times or distances of a specified origin (Handy and Niemeier, 1997). A simple example is

\[ A_i = \sum_j O_id_{ij}^{-b}, \]

where \( A_i \) is the accessibility of person \( i \), \( O_i \) is the number of opportunities (say, the number of job openings of a particular type or the number of grocery stores) at distance \( j \) from person \( i \)'s home, and \( d_{ij} \) is some measure of the friction of distance between \( i \) and \( j \) (this measure could be distance in kilometres, travel costs in euros or travel time in minutes). This equation could also be used to assess the relative levels of accessibility of different areas, such as census tracts; in this case, \( A_i \) is the accessibility of place \( i \), \( O_i \) is the number of opportunities in place \( j \), and \( d_{ij} \) is a measure of separation between places \( i \) and \( j \).

As is evident from the measure above, accessibility is affected by land-use patterns, mobility and mobility substitutes in the form of telecommunications. If many opportunities are located close to someone’s home or workplace, that person can enjoy a relatively high level of accessibility with relatively little mobility, and will be more likely to gain access to opportunities via walking or biking rather than via motorized modes (Hanson and Schwab, 1987). As opportunities are located at greater distances from each other and from residential areas, greater mobility is required to attain access. As the cost of overcoming spatial separation increases, all else being equal, accessibility decreases. Electronic communications such as the telephone and the internet enable access without mobility, although in most cases, such as that of purchasing a book from an online vendor, the cost of overcoming distance remains in the form of shipment costs (Scott, 2000b). These relationships among accessibility, mobility and land-use patterns are central to efforts to promote the urban village as an alternative to sprawl.

The advent of GIS technology has enabled the development of accessibility measures that recognize that a person’s access changes as that person moves about, for example, over the course of a day (Kwan, 1999). In addition, there is increasing recognition that the ability to take advantage of spatially dispersed employment opportunities, medical services and shops involves more than overcoming distance. Gaining access often entails overcoming barriers constructed by language and culture (as in the ability to access medical care), by lack of education or skills (as in access to certain jobs), or by gender ideologies (which prohibit women from entering certain places or place additional space–time constraints on women’s mobility). In short, lack of access involves more than spatial mismatch.

Suggested reading

accumulation The process by which capital is reproduced on an expanding scale through the reinvestment of surplus value. Accumulation of capital is possible within a variety of social structures, but for Marx accumulation was uniquely imperative within capitalist societies and therefore constituted a definitive condition of the capitalist mode of production (see capitalism).

In capitalist contexts, accumulation involves reinvesting the surplus value from past rounds of production, reconverting it into capital. Marx discussed different forms of accumulation that applied to different historical and geographical conditions of production. In early centuries of European capitalism, a crucial dimension of the accumulation process was enclosure of common lands and conversion of communal or tied labour into ‘free’ wage labour, through destruction of independent control over means of production. Marx described this process of primitive (or ‘primary’) accumulation as a historical precondition for the development of capitalism (Marx, 1967 [1867], pp. 713–41), but it has also been seen in more recent Marxist scholarship as a continuing dimension of the overall process of accumulation that Harvey (2003b, pp. 137–82) calls accumulation by dispossession (cf. Amin, 1974; see also marxian economics).

Within the capitalist mode of production proper, the major form of accumulation is what Marx calls ‘expanded reproduction.’ To remain in business, any given capitalist must at least preserve the value of the capital originally invested, what Marx calls ‘simple reproduction.’ But, as individual capitalists seek to more effectively extract surplus from labour, they employ new means of production (machinery and other technologies), the value of which can only be fully realized through expanding their scale of operation. This spurs competition over markets, and competition in turn comes to act as the enforcer of expanded accumulation.
reproduction. Any capitalist who chooses only to engage in simple reproduction would soon lose market share and go out of business. As Marx put the matter, ‘Accumulate, accumulate! That is Moses and the prophets!’ (Marx, 1967 [1867], p. 595).

This competition-enforced dynamic of accumulation shapes the geography of capitalist development. The search for new markets drives investors to intensify production and consumption within given locations, contributing to the development of the built environment and transforming social relations in ways that facilitate expanded reproduction (Harvey, 1999 [1982]). It also drives investors to seek opportunities in new locations, thus giving rise to a geographical expansion of capitalist relations of production and consumption, albeit in a highly uneven fashion when considered at a global scale (Amin, 1974; see UNEVEN DEVELOPMENT). Both intensive and extensive capitalist accumulation are fraught processes that do not occur automatically, and are shaped by numerous social struggles (Harvey, 2003b, pp. 183–211). The reproduction of capitalist social relations may or may not occur in given contexts, and may depend upon a variety of factors, including the roles played by states.

**acid rain** The deposition of sulphuric and nitric acids on to land or water by rainwater. Acid rain is one form of acid precipitation, which also includes acid snow, acid hail, dry deposition and acid fog condensation. On a pH scale of 14, a substance with a pH value of less than 7 is considered acidic, while a pH value greater than 7 is considered alkaline. Rainwater is naturally slightly acidic, with a pH value of about 5.6. Acid rain generally has an average pH range of 3–5. Acidity is greatest near the base of clouds, and is diluted by a factor of 0.5 to 1 pH during rainfall (Pickering and Owen, 1994).

The English chemist R. A. Smith discovered a link between industrial pollution and acid rain in Manchester in 1852, although it was known in the twelfth century that the burning of coal caused air pollution (Turco, 1997). Smith first used the term ‘acid rain’ in 1872, but his ideas have only been treated seriously since the late 1950s. The studies of Swedish soil scientist Svante Oden focused attention on this international issue. In 1972 the Swedish Government presented its case at the United Nations Conference on the Human Environment in Stockholm. The term ‘acid rain’ has been used extensively in recent decades.

Acid rain is caused primarily by the cumulative release of nitrogen and sulphur from the burning of fossil fuels. This includes coal for power, heating and industry, petrol in automobiles, and uncontrolled fires in coalfields and coal mines, particularly in northern China (Stracher and Taylor, 2004). While acid rain may occur through natural processes such as volcanic activity, it is the cumulative impact of human activities that has caused a marked increase in acid rain over the past century. Since about 1990 various Western countries have been generally successful in reducing their generation of acid precipitation, mostly through the closure of old factories, improved pollution control measures and the phasing out of domestic coal burning, but sulphur and nitrogen oxide emissions have increased rapidly in countries such as China (Cutter and Renwick, 2004).

Acid deposition is most severe in western Europe, the Midwest of North America, in China and in countries near its eastern borders. These areas have higher generation rates. Acid rain may cross national boundaries and fall several hundred kilometres from the source, particularly when tall smokestacks displace pollution from its source area. The areas most affected by acid rain tend to be downwind of dense concentrations of power stations, smelters and cities, are often in upland areas with high levels of precipitation, and are often forest areas dissected by rivers and lakes. Acid rain kills forests when acidic particles directly damage leaves, and/or when the soil becomes acidified and the metals bound in the soil are freed. The nutrients necessary for plant growth are then leached by the water. Acid rain lowers the pH value of lakes and other water bodies, which kills fish and other aquatic forms of life. Acid rain may also corrode buildings and other structures.

**action research** A synthesis between study of social change and active involvement in processes of change, where critical research, reflexive activism and open-ended pedagogy are actively combined in an evolving collaborative methodology.

By its very nature, action research interrogates the conventional idea of the academic researcher as an isolated expert who is authorized to produce knowledge about the marginalized ‘Other’. It seeks to eliminate the dichotomy between researcher and researched.
by involving research subjects as intellectual collaborators in the entire process of knowledge production: from agenda formation, analysis and decisions about forms that knowledge should take, to grappling with the intended and unintended outcomes emanating from the knowledges produced. In this sense, the relevance of research for social action is not primarily about helping the marginalized to identify their problems by fostering social awareness or militancy. Rather, relevance comes from deploying analytical mediation, theory-making and critical self-reflexivity in ways that allow people who are excluded from dominant systems of knowledge production and dissemination to participate in intellectual self-empowerment by developing critical frameworks that challenge the monopolies of the traditionally recognized experts (Sangtin Writers [and Nagar], 2006; see also PARTICIPANT OBSERVATION).

To avoid slipping into a romance of undoing the dominant norms of knowledge production, however, one must recognize that ‘participation,’ ‘transformation,’ ‘knowledge’ and ‘EMPOWERMENT’ are also Commodities with exchange values in the academic (and expertise) market. Rather than assuming social transformation to be the ultimate goal for a COMMUNITY, it is necessary to examine critically what motivates and legitimizes the production of social knowledge for social change or empowerment and to ask whether participation is a means or an end. Poetivin (2002, p. 34) points out that participation as a means runs the risk of becoming a manipulative device in the hands of urban researchers and social activists who can operate communication techniques and modern information systems with a missionary zeal. As an end, however, participation can become an effective democratic process, enabling intellectual empowerment and collective social agency.

Until the 1980s, action research was regarded as a largely unproblematic community-based and practice-oriented realm that was less theoretical than other forms of research. But such neat separation between action and theory has been successfully muddled by geographers whose work blends POST-STRUCTURALISM with a commitment to praxis (see APPLIED GEOGRAPHY). Such writing struggles with dilemmas of authority, privilege, voice and REPRESENTATION in at least three ways. First, it recognizes the provisional nature of all knowledge, and the inevitably problematic nature of translation, mediation and representation. Second, it underscores the importance of being attentive to the existence of multiple situated knowledges (frequently rooted in mutually irreconcilable epistemological positions) in any given context. Thus, negotiating discrepant audiences and making compromises to coalesce around specific issues are necessary requirements for academics who seek to engage with, and speak to, specific political struggles (Larner, 1995). Third, it suggests how specifying the limits of dominant DISCOURSES can generate dialogues across difference in ways that disrupt hegemonic modes of representation (Pratt, 2004).

**activism** The practice of political action by individuals or collectives in the form of social movements, non-government organizations and so on. Within GEOGRAPHY, this is related to discussions about the political RELEVANCE of the discipline to ‘real-world concerns’ and to practices of RESISTANCE. With the advent of RADICAL and MARXIST GEOGRAPHY in the 1960s came a concern to facilitate the direct involvement of geographers in the solving of social problems (e.g. Harvey, 1972). Early radical geographers called for the establishment of a people’s geography, in which research was focused on politically charged questions and solutions and geographers actively involved themselves with the peoples and communities that they studied (e.g. William Bunge’s 1969 ‘Geographical Expeditions’ in Detroit). The development of FEMINIST GEOGRAPHY has emphasized politically committed research, including promoting dialogue and collaboration between activist-academics and the people they study, as well as recognizing and negotiating the differential POWER relations within the research process. Another central concern has been the question of whom research is produced ‘for’ and whose needs it meets (Nast, 1994a; Farrow, Moss and Shaw, 1995).

Since the 1990s, geographers have lamented anew the separation between critical sectors of the discipline and activism both inside and outside the academy (e.g. Blomley, 1994a; Castree, 1999a; Wills, 2002: see CRITICAL HUMAN GEOGRAPHY). Calls have been made for critical geographers to become politically engaged outside the academy, collaborating with social movements, community groups and protests, among others, to interpret and effect social change (Chouinard, 1994b; Kobayashi, 1994; Routledge, 1996b; Fuller, 1999). Because
activism is gendered, classed, racialized and infused with cultural meanings depending on the context of struggle, collaboration requires theorizing and negotiating the differences in power between collaborators and the connections that they forge. Hence several authors have proposed that the differences between academic and activist collaborators are engaged in relational and ethical ways, aware of contingency and context (Katz, 1992; Slater, 1997; Kitchin, 1999; Routledge, 2002). This also demands acknowledgement of what Laura Pulido (2003) calls the ‘interior life of politics’: the entanglement of the emotions, psychological development, souls, passions and minds of activist-academic collaborators.

Activism is discursively produced within a range of sites, including the media, grassroots organizations and academia, and this has frequently led to a restrictive view of activism that emphasizes dramatic, physical and ‘macho’ forms of action. Ian Maxey (1999) has argued for a more inclusive definition of activism, as the process of reflecting and acting upon the social world that is produced through everyday acts and thoughts in which all people engage. Through challenging oppressive power relations, activism generates a continual process of reflection, confrontation and empowerment. Such an interpretation opens up the field of activism to everybody and serves to entangle the worlds of academia and activism (Routledge, 1996b; see also THIRD SPACE).

Recent calls for activist research have argued that academics have a social responsibility, given their training, access to information and freedom of expression, to make a difference ‘on the ground’ (Cumbers and Routledge, 2004; Fuller and Kitchen, 2004a), although such responsibility is not necessarily restricted to the immediate or very local (Maxey, 2004). Fuller and Kitchen see the role of the academic as primarily that of an enabler or facilitator, acting in collaboration with diverse communities. Radical and critical praxis is thus committed to exposing the socio-spatial processes that (re)produce inequalities between people and places; challenging and changing those inequalities; and bridging the divide between theorization and praxis. They bemoan the fact that there is still some scholarly distance between geographers’ activism and their teaching, as well as between their research and publishing activities, and that critical praxis consists of little else beyond pedagogy and academic writing. They posit that the structural constraints of the desire to maintain the power of the academy in knowledge production and the desire to shape the education system for the purposes of the neoliberal status quo work to delimit and limit the work of radical/critical geographers. Under such conditions, an activist geography entails making certain political choices or committing to certain kinds of action (Pain, 2003), where commitment is to a moral and political philosophy of social justice, and research is directed both towards conforming to that commitment and towards helping to realize the values that lie at its root (see also ACTION RESEARCH).

actor-network theory (ANT) An analytical approach that takes the world to be composed of associations of heterogeneous elements that its task is to trace. What became known as ANT emerged out of work being done within Science and Technology Studies (STS) during the 1980s by a group of scholars including, most notably, Bruno Latour, Michael Callon and John Law. Drawing on a diversity of conceptual influences ranging from the relational thought of philosopher of science Michel Serres and materialized post-structuralism of philosophers Michel Foucault and Gilles Deleuze to the practice-centred ethnomethodology of sociologist Harold Garfinkel and the narrative semiotics of Algirdas Greimas, these authors together produced the basis of a thoroughly empirical philosophy (Mol, 2002) that has now established itself as a serious alternative to more established SOCIAL THEORIES.

Latour (2005) suggests that what ANT offers as a ‘sociology of association’ is an uncertainty as to ‘what counts’ in a given situation, which stands in marked contrast to the approach of traditional ‘sociologies of the social’, where the salient factors are more or less determined in advance. The objective of ANT is thus to give things some room to express themselves such that the investigator can ‘follow the actors’ (to quote an oft-quoted ANT rule of method), letting them define for themselves what is or is not important. In practice, of course, such aspirations are profoundly difficult to operationalize, meaning that ANT studies rarely start from a completely blank slate and instead tend to repeatedly draw attention to a number of features of the world that are usually downplayed or ignored in classic social science accounts. This has led Law (1994) to suggest that ANT is perhaps better thought of as a ‘sensibility’ than a theory per se, an orientation to the world that brings certain
characteristics into view. Most notably, these include (1) the constitutive role of non-humans in the fabric of social life. Whether it is as ‘quasi-objects’ around which groups form, ‘matters of concern’ that animate sociotechnical controversies or ‘immutable mobiles’ through which knowledge travels in the durable guise of techniques and technologies, ANT takes things to be lively, interesting and important. This move can be seen as restoring agency to non-humans as long as it is appreciated that (2) agency is distributed, which is to say that it is a relational effect that is the outcome of the assemblage of all sorts of social and material bits and pieces. It is these actor networks that get things done, not subjects or objects in isolation. Actors are thus networks and vice versa, hence the significance of the always hyphenated ‘actor-network theory’. Making and maintaining actor-networks takes work and effort that is often overlooked by social scientists. Callon (1986) terms this mundane but necessary activity the ‘process of translation’, within which he elaborates four distinctive movements. This concern with the work of the world also helps to explain the ongoing attraction of sociotechnical controversies to ANT practitioners as sites not only of political significance, but also where science and society can be observed in real time.

Advocates of ANT often express modesty and caution regarding how far the findings of their specific case studies might be extended. However, the approach itself offers a radical challenge to the organizing binaries of modernity, including nature and culture, technology and society, non-human and human and so on. Viewed from an ANT perspective, these are, at best, the outcomes of a whole range of activities (as opposed to the appropriate starting points for action or analysis). At worst, they are political shortcuts that serve to bypass the due democratic consideration that our collective ‘matter of concerns’ deserve.

With its combination of a transferable toolkit of methods and far reaching conceptual implications, it is perhaps not surprising that ANT has begun to travel widely, far beyond the laboratories where it started into fields as various as art, law and economics. In geography, the particular appeal of ANT has been that it speaks to two of the discipline’s most long-standing concerns. On the one hand, the approach has proved helpful to those seeking to enrich and enliven understanding of the relationships between humans and non-humans whether coded ‘technological’ (e.g. Bingham, 1996) or ‘natural’ (e.g. Whatmore, 2002a; Hinchliffe, 2007). On the other hand, ANT’s tendency to at once ‘localise the global’ and ‘redistribute the local’ (Latour, 2005) has been both employed and extended by geographers seeking to understand how action at a distance is achieved in a variety of contexts (e.g. Thrift, 2005b; Murdoch, 2005).

Despite internal debates about everything from the appropriateness of the term (Latour, 2005) to whether we are now ‘after ANT’ (Law and Hassard, 1999), there can be little doubt that the sensibility, and probably the term, is here to stay – if still very much a work in progress. One indication of this is the fact that there now exist a number of standard criticisms of ANT. These include the charges that it ignores the structuring effects of such classic sociological categories as race, class and gender and that it underplays the influence of power in society. Whether such dissenting voices represent valid concerns or are an indication of the challenge that ANT poses to traditional social science thinking is a matter of judgement. More significant, perhaps, for the future of ANT is that a number of its most influential figures have begun to address such criticisms in more or less direct ways, armed with a newly identified set of antecedents (including Gabriel Tarde, John Dewey and Alfred North Whitehead). Prompted in part by contemporary work around the edges of ANT, such as the cosmopolitical thinking of the Belgian philosopher of science Isabelle Stengers (2000) and the ‘politics of what’ promoted by Dutch philosopher Annemarie Mol, recent work in the field is concerned not only with how the world is made, unmade and remade, but also with the better and worse ways in which the social is and might be reassembled. Whether this marks the start of a ‘normative turn’ for ANT it is too early to tell, but will be worth following.

adaptation Derived from Darwinian and evolutionary theory (cf. darwinism; lamarckianism), adaptation is an enormously influential metaphor for thinking about the relations between populations (human and non-human) and their environment (Sayer, 1979). It is a concept with a long and robust life in the biological and social sciences. Adaptation is rooted in the question of survival, and specifically of populations in relation to the biological environments that they inhabit (Holling, 1973). Adaptation refers to the changes in
gene frequencies that confer reproductive advantage to a population in specific environments, and to physiological and sociocultural changes that enhance individual fitness and well-being.

Adaptation has a currency in the social sciences through the organic analogy – the idea that social systems are forms of living systems in which processes of adaptation inhere (Slobodkin and Rappaport, 1974). In geography, CULTURAL and HUMAN ECOLOGY drew heavily on biological and adaptive thinking by seeing social development in terms of human niches, adaptive radiation and human ecological succession (see Watts, 1983b). Some of the more sophisticated work in cultural ecology (Nietschmann, 1973) drew upon the work of Rappaport (1979), Wilden (1972) and Bateson (1972), who employed systems theory (cf. SYSTEMS ANALYSIS), cybernetics and ECOSYSTEMS modelling as a way of describing the structure of adaptation in PEASANT and tribal societies. Here, adaptation refers to the ‘processes by which living systems maintain homeostasis in the face of short-term environmental fluctuations and by transforming their own structures through long-term non-reversing changes in the composition and structure of their environments as well’ (Rappaport, 1979, p. 145). There is a structure to adaptive processes by which individuals and populations respond, in the first instance, flexibly with limited deployments of resources and over time deeper more structural (and less reversible) adaptive responses follow. Maladaptation in this account refers to processes – pathologies – by which an orderly pattern of response is compromised or prevented. In social systems, these pathologies emerge from the complex ordering of societies. Cultural ecology and ecological anthropology focused especially on rural societies in the THIRD WORLD to demonstrate that various aspects of their cultural and religious life fulfilled adaptive functions. Adaptation has also been employed however by sociologists, geographers and ETHNOGRAPHERS in contemporary urban settings as a way of describing how individuals, households and communities respond to and cope with new experiences (MIGRATION, POVERTY, VIOLENCE) and settings (the CITY, the PRISON). In the human sciences, the term ‘adaptation’ has, however, always been saddled with the baggage of STRUCTURAL FUNCTIONALISM on the one hand and biological reductionism on the other (Watts, 1983b). Much of the new work on RISK and vulnerability – whether to global climate change or the resurgence of infectious diseases – often deploys the language or intellectual architecture of adaptation. MW

aerotropolis A term introduced by Kasarda (2000) referring to urban developments focused on major airports, which increasingly act as major economic centres and urban development, for both aeronautical- and non-aeronautical-related activities: Kasarda likens them to traditional CENTRAL BUSINESS DISTRICTS, with important retail, hotel, entertainment and conference facilities, drawing on wider clienteles than those who fly into the airport at the development’s core. Increasingly, land-use planning focuses on airports as major economic development cores. RJJ

affect The intensive capacities of a body to affect (through an affection) and be affected (as a result of modifications). The concept is used to describe unformed and unstructured intensities that, although not necessarily experienced by or possessed by a subject, correspond to the passage from one bodily state to another and are therefore analysable in terms of their effects (McCormack, 2003). In contemporary HUMAN GEOGRAPHY, there is no single or stable cultural-theoretical vocabulary to describe affect. It is possible to identify at least five attempts to engage with affects as diffuse intensities that in their ambiguity lie at the very edge of semantic availability: work animated by ideas of PERFORMANCE; the psychology of Silvan Tomkins; neo-DARWINISM; Gilles Deleuze’s ethological re-workings of Baruch Spinoza; and post-Lacanian psychoanalysis (see PSYCHOANALYTIC THEORY) (Thrift, 2004a).

Within these five versions, the most in-depth has been the engagement of NON-REPRESENTATIONAL THEORY with Deleuze’s creative encounter with the term affectus in the work of the seventeenth-century philosopher Baruch Spinoza (which had been translated as ‘emotion’ or ‘feeling’). This begins from an analytic distinction between affect and other related modalities, including emotion and feeling (Anderson, 2006b), and is organized around two claims. First, affects can be described as impersonal or pre-personal, as they do not necessarily belong to a subject or inhabit a space between an interpretative subject and an interpreted object. Rather, affects can be understood as autonomous, in that they are composed in and circulate through materially heterogeneous ASSEMBLAGES. This retains the
connotation that affects come from elsewhere to effect a subject or self. Second, affect is equivalent to intensity in that it does not function like a system of signification, but constitutes a movement of qualitative difference. The relationship between the circulation and distribution of affects and signification is not, therefore, one of conformity or correspondence, but one of resonation or interference.

Unlike other versions of what affect is and does, non-representational theory’s engagement with the term is based on a distinction between affect and emotion – where emotion is understood as the socio-linguistic fixing of intensity that thereafter comes to be defined as personal (cf. EMOTIONAL GEOGRAPHY). The term ‘affect’ has thus been central to non-representational theory’s break with signifying or structuralizing versions of CULTURE. The difficulties that affect poses for social analysis – how to describe the circulation and distribution of intensities – have been engaged through the creation of new modes of witnessing that learn to pay attention to the inchoate, processual, life of spaces and places (Deburbury, 2003). Alongside this development of new methodological repertories has been a growing recognition that understanding the circulation and distribution of affect is central to engagements with a contemporary political moment in which affect has emerged as an object of contemporary forms of BIOPOWER and BIOPOLITICS (Thrift, 2004a). In response, a range of work has begun to articulate and exemplify the goals and techniques of a spatial politics and/or ETHICS that aims to inventively respond to and intervene in the ongoing composition of spaces of affect (McCormack, 2003).

McCormack (2003); Thrift (2004a).

Africa (idea of) Geography, as an institutionalized field of knowledge, figures centrally in both the history of informal and formal colonial rule in Africa and in the ways in which Africa came to be represented in the West – and in turn how the West has represented itself to itself – especially from the eighteenth century onwards. In his important and controversial book Orientalism (2003 [1978]), Edward Said reveals how ideas and knowledge, while complex and unstable, are always inseparable from systems of subjection. In his case, ORIENTALISM represents a body of European knowledge, a geography of the Orient, which not only helped construct an imperial vision of particular places and subjects but displaced other voices, and indeed had material consequences as such ideas became the basis for forms of rule. In an almost identical fashion, the history of geographical scholarship, and of academic geography, in particular in the nineteenth and early twentieth centuries, was closely tied to the European imperial mission in Africa. The Royal Geographical Society (RGS) was formed in 1830 as an outgrowth of the Africa Association, and Britain’s overseas expansion in the nineteenth century (in which Africa figured prominently, especially after 1870) was by and large orchestrated through the RGS. Similarly, the Franco-Prussian War (1870–1) directly stimulated an increase in French geographical societies, which helped sustain a coherent political doctrine of colonial expansion, not least in Africa. At the Second International Congress of Geographical Sciences held in 1875, and attended by the president of the French Republic, knowledge and conquest of the Earth were seen as an obligation, and GEOGRAPHY provided the philosophical justification.

Africa was central to, and to a degree constitutive of, the troika of geography, RACE and EMPIRE. European geography helped create or, more properly, invent a sort of Africanism, and relatedly a particular set of tropical imaginaries or visions embodied in the emergent field of tropical geography (see TROPICALITY). Equally, Africa played its part in the debates within geography over ENVIRONMENTAL DETERMINISM, race and CIVILIZATION, and in what Livingstone called the moral economy of climate; Africa helped invent geography. The iconography of light and darkness portrayed the European penetration of Africa as simultaneously a process of domination, enlightenment and liberation. Geography helped make Africa ‘dark’ in the nineteenth and twentieth centuries, as it simultaneously assisted in the means (military cartography) by which the darkness was to be lifted by the mission civilisatrice. In a sense, then, the study of Africa lay at the heart of academic geography from its inception.

The idea of Africa and its genealogical provenance in the West is far too complex to be sketched here. Suffice to say that Stanley Crouch is quite right when he writes that Africa is ‘one of the centerpieces of fantasy of our time’ (Crouch, 1990). Africa was after all, in the words of Joseph Conrad’s Marlow in Heart of darkness (2007 [1902]), ‘like travelling back to the earliest beginnings of the world’. It is no surprise that one of the most important texts
on contemporary Africa – Achille Mbembe’s *Postcolony* (2001) – begins with the statement that Africa stands as the ‘supreme receptacle’ of the West’s obsession with ‘absence’, ‘non being’ – in short, ‘nothingness’ (p. 4). The Hegelian idea that Africa was a space without history has been elaborated so that Africa’s special feature is ‘nothing at all’. It is against this sort of dehistoricization that so much intellectual effort has been put – by African intellectuals in particular – to account for another idea of Africa, one that approaches what Bayart (1993) calls ‘the true historicity of African societies’.

A history of geographers and geographical practice in the service of colonial rule in Africa has yet to be written, but it is quite clear that geographical ideas, most obviously land use and agrarian change, population growth and mobility, and environmental conservation, run through the period from the imperial partitioning of Africa in the 1870s to the first wave of independence in 1960. Richard Grove (1993) has traced, for example, early conservation thinking in the Cape in southern Africa to the 1811–44 period, which had produced a conservation structure of government intervention by 1888, driven by a triad of interests: scientific botany, the white settler community and government concerns for security. This tradition of land use and conservation was inherited by various colonial officials in Africa, and reappeared across much of western and southern Africa in the 1930s in a debate over population growth, deforestation and the threat of soil erosion. In colonial British West Africa, the rise of a populist sentiment in agricultural policy singing the praises of the smallholder and the African PEASANT is very much part of the historiography of cultural ecological thinking in geography as a whole (see CULTURAL ECOLOGY).

The relevance of geography’s concern with land use and HUMAN ECOLOGY for colonial planning in Africa (and elsewhere) was vastly enhanced by what one might call the ‘invention of DEVELOPMENT’ in the late colonial period. While the word ‘development’ came into the English language in the eighteenth century with its root sense of unfolding, and was subsequently shaped by the Darwinian revolution a century later, development understood as a preoccupation of public and international policy to improve welfare and to produce governable subjects is of much more recent provenance. Development as a set of ideas and practices was, in short, the product of the transformation of the colonial world into the independent developing world in the postwar period. Africa, for example, only became an object of planned development after the Depression of the 1930s. The British Colonial Development and Welfare Act (1940) and the French Investment Fund for Economic and Social Development (1946) promoted modernization in Africa through enhanced imperial investment against the backdrop of growing nationalist sentiments. After 1945, the imperial desire to address development and welfare had a strong agrarian focus, specifically productivity through mechanization, settlement schemes and various sorts of state interventions (marketing reform, co-operatives), all of which attracted a good deal of geographical attention. Growing commercialization in the peasant sector and new patterns of population mobility and demographic growth (expressed largely in a concern with the disruptive consequences of URBANIZATION and rural–urban migration) pointed to land use as a central pivot of geographical study.

Geography was a central practical field in the mapping of the continent. At the Treaty of Berlin (1895) when Africa was partitioned, the maps produced by geographers were for the most part incomplete and inadequate. But the harnessing of cartography to the colonial project was an indispensable component of colonial rule and the exercise of power. Cadstral surveys were the ground on which Native Authorities and tax collection were to be based, but fully cadastral mapping proved either too expensive or too political. New critical studies in cartography have provided important accounts of the institutionalized role of mapping in colonial (and post-colonial) rule and its use as an exercise of power (see CARTOGRAPHIC REASON; CARTOGRAPHY). The mapping of Africa is still ongoing and the delimitation of new territories (whether states, local government areas or chiefdoms) remains a complex process, wrapped up with state power and forms of representation that are not captured by the purported objective qualities of scientific map production.

Colonial rule in Africa proved to be relatively short, little more than one lifetime long, and produced neither mature capitalism nor a standard grid of imperial rule. Whether settler colonies (Kenya), peasant-based trade economies (Senegal) or mine-labour reserves (Zaire), in the 1960s virtually all the emerging independent African states shared a common imperial legacy: the single-commodity economy. African economies were one-horse towns, hitched to the world market through
primary export commodities such as cotton, copper and cocoa. However distorted or neo-colonial their national economies, African hopes and expectations at independence were high – indeed, in some sense almost euphoric. The heady vision of Kwame Nkrumah – of a black Africa utilizing the central-planning experience of the Soviet Union to industrialize rapidly and overcome poverty, ignorance and disease – captured the popular imagination. Indeed, among the first generation of African leaders, irrespective of their political stripe, there was an infatuation with national plans and ambitious long-term planning. Health, education and infrastructure were heavily funded (typically aided and abetted by technical foreign assistance), and government activities were centralized and expanded to facilitate state-led modernization. In spite of the fact that state agencies extracted surpluses from the agrarian sector – peasant production remained the bedrock of most independent states – to sustain import-substitution and industrialization (as well as a good deal of rent-seeking and corruption by elites), African economies performed quite well in the 1960s, buoyed by soaring commodity prices (especially after 1967).

Not surprisingly, much of the geographical scholarship of the 1960s was framed by some variant of modernization theory, or at the very least by the presumption that the processes of modernity (commercialization, urbanization and transportation) were shaping indigenous institutions and practices. From the onset of the 1970s, the complacency and optimism of the 1960s appeared decidedly on the wane. Mounting US deficits, the devaluation of the dollar and the emergence of floating exchange rates marked the demise of the postwar Bretton Woods financial order. The restructuring of the financial system coincided with the crisis of the three F’s (price increases in fuel, fertilizer and food) in 1972–3, which marked a serious deterioration in Africa’s terms of trade. Ironically, the oil crisis also contained a solution. Between 1974 and 1979, the balance-of-payments problems of many African states (which faced not only a quadrupling of oil prices but a general price inflation for imported goods and a sluggish demand for primary commodities) was dealt with through expansionary adjustment: in other words, through borrowing from banks eager to recycle petrodollars or from the special facilities established by the International Monetary Fund (IMF) and the World Bank. Expansionary adjustment, however, deepened two already problematic tendencies in African political economies. The first was to enhance the politics of public-sector expansion, contributing to waste, inefficiency and the growing privatization of the public purse. The second was to further lubricate the political machinery, which produced uneconomic investments with cheaply borrowed funds.

The crisis of the 1970s helped to precipitate two major changes in the institutional and theoretical climate of Africanist geography. On the one hand, the spectre of famine in the Sahel and the Horn drew increased foreign assistance to sub-Saharan Africa as a whole and to rural development in particular. To the extent that this support translated into research and programming activities in the donor countries, academics and consultants were drawn into development and applied work, in the USA through USAID, in the UK through the Ministry of Overseas Development, and in France through the Office de la Recherche Scientifique et Technique d’Outre-Mer (ORSTOM). In the USA in particular, USAID-funded projects permitted some campuses to expand their Africanist activities and encouraged some geographers to systematically explore a number of questions relating to drought, food security and rural resource use. On the other, the bleak prospects for Africa in the face of a world recession and deteriorating terms of trade, prospects that contributed to the call for a new international economic order in the first part of the 1970s, were not unrelated to the growing critique of market-oriented modernization theory and the early growth theorists, and to the gradual emergence, beginning in the late 1960s, of radical dependency theory, and subsequently of Marxist-inspired development theory (Watts, 1983a).

The precipitous collapse in the 1980s brought on by drought, famine, AIDS, bankruptcy, civil strife, corruption, the conflation of troubles, was matched by an equally dramatic rise of neo-liberal theory (see neoliberalism) – what John Toye (1987) has called the counterrevolution in development theory. Championing the powers of free and competitive markets – and by extension the assault on the state-led post-colonial development strategies of most African states – while popular in the halls and offices of the World Bank and various development agencies, was an object of considerable theoretical debate. Some geographical scholarship had certainly been critical of state-initiated development schemes, but the myopic prescriptions for free markets were properly criticized for their impact on the poor, for their dismissal of the
institutional prerequisites for market capitalism and as a basis for sustained accumulation. At the same time, the adjustment had devastating consequences on university education in Africa, with the result that research by African geographers was seriously compromised. African scholarship generally withered to the point of collapse as faculties faced the drying up of research monies, compounded by declining real wages. Many academics were compelled to engage in second occupations. The most active African geographers were those who were based outside of the continent or who acted as consultants to international development agencies.

By the new millennium two other issues had, in a curious way, come back to haunt Africa, raising difficult and profound questions about the way Africa is, and has been, inscribed through Western discourse. One is rooted in debates that stretch back to the end of the eighteenth century and the other is relatively new. The Malthusian spectre (see MALTHUSIAN MODEL) hangs over the continent and has pride of place in the major policy documents of global development agencies. Some geographers, working largely within a Boserupian problematic (see BOSERUP THESIS), had explored the relations between demographic pressure and land use during the 1980s, but the new demographic debate is driven increasingly by the presumption of persistently high fertility rates (in some cases over 4 per cent per annum), rapid environmental degradation (the two are seen to be organically linked) and what is widely held to be the extraordinarily bleak economic future in the short term for most African economies. AIDS, conversely, is of late-twentieth-century provenance, but its history has been, from its inception, linked (often falsely) to Africa. While the statistics are contested on virtually every front, work by geographers has begun to draw out the patterns and consequences of terrifyingly high rural and urban infection rates in the east and central African arc.

Whether the human geography of Africa has approached Edward Said’s goal to produce a geography of African historical experience remains an open question. What the most compelling geographies of the 1980s and 1990s accomplished, nonetheless, was the addition of complexity to our understanding of African places and spaces (Hart, 2003; Moore, 2005). Since 2000, there is no question that Africa has gained a newfound international visibility. Driven in part by the debt question and the efforts of the likes of Bono, Gordon Brown in his time at the British Exchequer, the New Economic Partnership for Africa (NEPAD), and the so-called ANTI-GLOBALIZATION movement, Africa is now the focus of substantial global concern. The conjuncture of a number of forces have brought the continent to a sort of impasse: the HIV/AIDS epidemic, the limited success of the austerity and adjustment reforms, a continuing decline in their share of world trade and foreign direct investment, the failure to meet the 2005 Millennium Goals, and the rise of massive cities (mega-cities) dominated by slums. The Commission on Africa (‘Blair Report’) and the US Council of Foreign Relations Task Force on Africa Report – both released in 2005 – speak in quite different registers to the challenges that geographical scholarship and practice must speak to. The growing significance of Africa in US ‘energy security’, in which the Gulf of Guinea figures so centrally, is one area in which the long-standing interest of geographers in strategic resources will continue to develop. ageing The process of becoming chronologically older, something affecting all lifeforms, but which in the social sciences becomes significant to the study of human populations and their internal differentiation. POPULATION GEOGRAPHY reconstructs the age profiles of populations within areas, noting the relative sizes of different age cohorts, and examining the DEMOGRAPHIC TRANSITION ensuing if fertility and mortality rates both decline and prompt the overall ageing of a population. This latter phenomenon is an oft-remarked feature of the more-developed world, with implications such as the increasing tax burden placed on the working age cohort, allied to increasing needs for specialist social, health and personal services for the growing elderly cohort (e.g. Andrews and Phillips, 2005).

Other researchers directly tackle the worlds and experiences of older people. While the broad field of gerontology (the study of such people) has prioritized a ‘medical model’, concentrating on the biological facts of ‘senescence’ (reduced mobility, deteriorating sight etc.), social scientists – looking to social gerontology – increasingly favour a ‘social model’, emphasizing instead society’s progressive withdrawal from and even exclusion of its older members (as in the Western orthodoxy of ‘retiring’ people at c. 60–70 years). The
social model acknowledges ageism as discriminatory ideas and practices directed at people solely because of their age, specifically when this is old age, the latter being influenced by negative portrayals involving ‘impotency, ugliness, mental decline, … uselessness, isolation, poverty and depression’ (Vincent, 1999, p. 141). Countering such ageism, it is argued that many societies historically and beyond the West respond respectfully to their elders, regarding them as sources of wisdom, balanced judgement and effective political leadership. Many older people shatter the stereotypes, moreover, and are healthy, active and able to lead lives that are personally fulfilling and socially worthwhile. A tension nonetheless arises between the relative bleakness of the social model (e.g. Vincent, 1999), stressing the iniquities pressing on elder life, and a vision of the ‘freedoms’ now enjoyed by many older people as consumers buying into a dizzying variety of cultural practices (e.g. Gilleard and Higgs, 2000). Much depends on other dimensions of social being, such as class, ethnicity and gender, which differentially impact the life experiences of different elderly population segments, and there is also an emerging distinction between the ‘younger old’ and the ‘older old’ (the latter, 85 + years, now being seen as the real ‘other’ emblematic of old age: Gilleard and Higgs, 2000, pp. 198–9).

These issues have all figured in geographical scholarship on ageing and elderly people. While children have recently attracted concerted geographical research attention, parallel work on elderly people remains fragmented, lodged in different corners of social, cultural, economic, population and medical geographies and various studies of disability. Some attempts have been made to delineate an overall field of ‘gerontological geography’ (Golant, 1979; Warnes, 1990), and to examine the intersections of ageism, other bases of identity and the socio-spatial worlds of old age (Laws, 1993; Harper and Laws, 1995; Pain, Mowl and Talbot, 2000). More specific studies have considered: the migration patterns traced out by elderly people, notably to ‘amenity destinations’ in coastal areas, rural ‘idylls’ and even purpose-built ‘retirement villages’ (Rogers, 1992); the daily activity spaces of elderly people, including the possible diminishing of such spaces attendant on both increasing bodily frailty and loss of social roles (Golant, 1984); the everyday environmental experience of elderly people in residential neighbourhoods, particularly those of the city, including the meanings and memories attaching to the quite mundane, peopled, object-filled places all around them (Rowles, 1978; Golant, 1984); and the growth of ‘nursing homes’ of different kinds, with definite locational and internal spatial configurations, which can be critiqued as zones of exclusion, putting boundaries between dependent elderly people and the rest of the population (Rowles, 1979; Phillips, Vincent and Blacksell, 1988).

**agent-based modelling** An approach to understanding decision-making and its consequences through simulation models, which require substantial computing power. Agent-based models recognize the interconnections and spatial dependencies among people and places: a large number of agents make decisions that affect others who respond in a dynamic process, the outcomes of which can be identified and – in geographical applications – mapped (cf. game theory). The collective outcomes may be unexpected, even when the individual agents’ decision-making criteria are fairly simple (cf. rational choice theory). Complex patterns ‘emerge’ from the interaction of a large number of simple decisions, which is one of the hallmarks of the burgeoning science of complexity (Holland, 1995). In this sense, agent-based modelling conceives of the world as being generated from the bottom up, in contrast to an earlier generation of models in the social sciences which were aggregative, working from the top down (as in gravity models).

A classic agent-based model of spatial patterns and processes was developed by Schelling’s (1971) work on ethnic residential segregation. His agents were households that had preferences for the type of neighbourhood in which they lived – such as for whites that ‘no more than half of their immediate neighbours should be black’. Individuals were randomly distributed across a checkerboard representation of an urban environment, and those whose situation did not match their preferences sought moves to vacancies where the criteria were met. Schelling showed that the equilibrium solution would almost certainly be a greater level of segregation than expressed in the preferences – for example, although whites would be content if their neighbourhoods were 50 per cent black, most of them would live in areas where whites were in a large majority. With increases in
computing power much more complex models can be run, which continue to provide the somewhat counter-intuitive result that segregation is greater than people’s individual preferences suggest (Fossett, 2006).

Agent-based modelling is widely used in the social sciences – in, for example, modelling the spread of diseases (cf. EPIDEMIOLOGY), traffic-generation, LAND USE AND LAND COVER CHANGE, the DIFFUSION of ideas, MIGRATION, crowding in small spaces and inter-firm competition (see http://www.econ.iastate.edu/testfatsi/ace.htm). agglomeration The association of productive activities in close proximity to one another. Agglomeration typically gives rise to EXTERNAL ECONOMIES associated with the collective use of the INFRASTRUCTURE of transportation, communication facilities and other services. Historically, there has been a tendency for economic activity to concentrate spatially, the large markets associated with metropolitan areas adding to the external cost advantages. Agglomeration also facilitates the rapid circulation of capital, commodities and labour. In some circumstances, DECENTRALIZATION may counter agglomerative tendencies; for example, if land costs and those associated with congestion in the central area are very high. (See also ECONOMIES OF SCALE; ECONOMIES OF SCOPE.) DMS

aggregate travel model A statement, often expressed as an equation, that predicts some aspect of travel (e.g. the number of trips or travel mode) for units (e.g. individuals or households) aggregated to small areas, often called ‘traffic analysis zones’. The data are collected and analysed for these zones, obscuring differences that may exist within zones and, because zones do not make travel decisions, rendering impossible investigation of decision-making processes underlying travel. For example, number of trips generated by a zone may be predicted as a function of the zone’s average household income and average number of vehicles per household. Aggregate travel models have been fundamental to transportation planning since the 1950s. SHA

agrarian question The forms in which capitalist relations transform the agrarian sector, and the political alliances, struggles and compromises that emerge around different trajectories of agrarian change. The founding theoretical text in studies of the agrarian question is Karl Kautsky’s The agrarian question, first published 1899 (but not translated into English until the 1980s). Kautsky’s focus on the agrarian question in western Europe rested on a striking paradox: agriculture (and the rural) came to assume a political gravity precisely at a moment when its weight in the economy was waning. Agriculture’s curious political and strategic significance was framed by two key processes: the first was the growth and integration of a world market in agricultural commodities (especially STAPLES) and the international competition that was its handmaiden; and the second was the birth and extension into the countryside of various forms of parliamentary DEMOCRACY. International competition in grains was driven not only by the extension of the agricultural FRONTIER in the USA, in Argentina, in Russia and in eastern Europe (what Kautsky called the ‘colonies’ and the ‘Oriental despotisms’), but also by improvements in long-distance shipping, by changes in taste (e.g. from rye to wheat) and by the inability of domestic grain production to keep up with demand. As a consequence of massive new supplies, grain prices (and rents and profits) fell more or less steadily from the mid-1870s to 1896 (Konig, 1994). It was precisely during the last quarter of the nineteenth century when a series of protectionist and TARIFF policies in France (1885), Germany (1879) and elsewhere were implemented to insulate the farming sector. New World grain exports were but one expression of the headlong integration of world commodity and capital markets on a scale and with an intensity then without precedent and, some would suggest, unrivalled since that period.

Kautsky then devoted much time to the Prussian Junkers and their efforts to protect their farm interests. But in reality the structure of protection only biased the composition of production in favour of grains (and rye in particular) grown on the East Elbian estates. Tariffs provided limited insulation in the protectionist countries, while the likes of England, The Netherlands and Denmark actually adopted free TRADE (Konig, 1994). Protection did not, and could not, save landlordism but was, rather, a limited buffer for a newly enfranchised PEASANT agriculture threatened by the world market. The competition from
overseas produce ushered in the first wave of agricultural protectionism, and in so doing established the foundations of the European ‘farm problem’, whose political economic repercussions continue to resonate in the halls of the European Commission, the GATT/WTO and trade ministries around the world (Fennell, 1997).

The agrarian question was a product of a particular political economic conjuncture, but was made to speak to a number of key theoretical concerns that arose from Kautsky’s careful analysis of the consequences of the European farm crisis: falling prices, rents and profits coupled with global market integration and international competition. In brief, he discovered that: (i) there was no tendency for the size distribution of farms to change over time (capitalist enterprises were not simply displacing peasant farms – indeed, German statistics showed that middle peasants were increasing their command of the cultivated area); (ii) technical efficiency is not a precondition for survivorship (but self-exploitation might be); and (iii) changes driven by competition and market integration did transform agriculture, but largely by shaping the production mix of different enterprises, and by deepening debt-burdens and patterns of out-migration rather than by radically reconfiguring the size distribution of farms. The crisis of European peasants and landlords in the late nineteenth century was ‘resolved’ by intensification (cattle and dairying in particular in a new ecological complex) and by the appropriation of some farming functions by capital in processing and agro-industry (see also Goodman, Sorj and Wilkinson, 1987: see also AGRO-FOODSYSTEM).

Kautsky concluded that industry was the motor of agricultural development – or, more properly, agro-industrial capital was – but that the peculiarities of agriculture, its biological character and rhythms (see Mann, 1990; Wells, 1996), coupled with the capacity for family farms to survive through self-exploitation (i.e. working longer and harder in effect to depress ‘wage levels’), might hinder some tendencies; namely, the development of classical agrarian capitalism. Indeed, agro-industry – which Kautsky saw in the increasing application of science, technology, and capital to the food processing, farm input and farm finance systems – might prefer a non-capitalist farm sector. In all of these respects – whether his observations on land and part-time farming, of the folly of land redistribution, his commentary on international competition and its consequences, or on the means by which industry does or does not take hold of land-based production – Kautsky’s book was remarkably forward-looking and prescient.

Terry Byres (1996) has suggested that there are three agrarian questions. The first, posed by Engels, refers to the politics of the agrarian transition in which peasants constitute the dominant class: What, in other words, are the politics of the development of agrarian CAPITALISM? The second is about production and the ways in which market competition drives the forces of production towards increased yields (in short, surplus creation on the land). And the third speaks to ACCUMULATION and the flows of surplus, and specifically inter-sectoral linkages between agriculture and manufacture. The latter Byres calls ‘agrarian transition’, a term that embraces a number of key moments; namely, growth, TERMS OF TRADE, demand for agrarian products, proletarianization, surplus appropriation and surplus transfer. Byres is concerned to show that agriculture can contribute to industry without the first two senses of the agrarian question being, as it were, activated, and to assert the multiplicity of agrarian transitions (the diversity of ways in which agriculture contributes to capitalist INDUSTRIALIZATION with or without ‘full’ development of capitalism in the countryside). While Byres’ approach has much to offer, it suffers from a peculiar narrowness. On the one hand, it is focused on the internal dynamics of change at the expense of what we now refer to as GLOBALIZATION. On the other, the agrarian question for Byres is something that can be ‘resolved’ (see also Bernstein, 1996). ‘Resolved’ seems to imply that once capitalism in agriculture has ‘matured’, or if capitalist industrialization can proceed without agrarian capitalism (‘the social formation is dominated by industry and the urban bourgeoisie’), then the agrarian question is somehow dead. This seems curious on a number of counts, not the least of which is that the three senses of the agrarian question are constantly renewed by the contradictory and UN Even DEVELOPMENT of capitalism itself. It is for this reason that we return to Kautsky, since his analysis embraces all three dimensions of the agrarian question (something seemingly not acknowledged by Byres) and because he focused so clearly on substantive issues central to the current landscape of AGRO-FOOD SYSTEMS: globalization, vertical INTEGRATION, the importance of biology in food provisioning, the application of science, the shifts of POWER off farm, the intensification of land-based activities and the new dynamisms associated
with agro-processing (McMichael, 1996; Goodman and Watts, 1997). Of course, Kautsky could not have predicted the molecular revolution and its implications for the role of intellectual property rights and so on. But it is an engagement with his work that remains so central to current studies of modern agriculture.

The role of SOCIALISM also stands in some tension to the agrarian question. After 1917, Russian theoreticians of rather different stripes – for example, Chayanov and Preobrazhensky – posited a type of socialist agrarian question in which peasants were collectivized into either state farms or co-operatives (Viola, 1996), sometimes in practice through extraordinary violence and compulsion. There were very different experiences across the socialist world as regards the means by which socialist agricultural surpluses were generated and appropriated by the state (here, for example, the Soviet Union and China are quite different). In the same way, the fall of actually existing socialism after 1989 produced a circumstance in which a new sort of agrarian question emerged as agrarian socialism was decollectivized – in the Chinese case, for example, gradually producing, after 1978, several hundred million peasants (Zweig, 1997).

Kautsky was, of course, writing towards the close of an era of protracted crisis for European agriculture, roughly a quarter of a century after the incorporation of New World agriculture frontiers into the world grain market had provoked the great agrarian depressions of the 1870s and 1880s. A century later, during a period in which farming and transportation technologies, diet and agricultural commodity markets are all in flux, the questions of competition, shifting terms of trade for agriculture and subsidies remain politically central in the debates over the European Union, GATT and the neo-liberal reforms currently sweeping through the third world. Like the 1870s and 1880s, the current phase of agricultural restructuring in the periphery is also marked (sometimes exaggeratedly so) by a phase of ‘democratization’ (Kohli, 1994; Fox, 1995: cf. core-periphery model). Agrarian parallels at the ‘centre’ can be found in agriculture’s reluctant initiation into the GATT/WTO trade liberalization agreement, albeit with a welter of safeguards and, relatedly, the dogged rearguard action being fought by western European farmers against further attempts to renegotiate the postwar agricultural settlement, which reached its protectionist apotheosis in the Common Agricultural Policy (CAP) during the 1980s. It is a picture clouded, however, by the strange bedfellows that the CAP has joined in opposition, including environmentalists, food safety activists, animal liberationists, bird watchers, rural preservationists and neo-conservative free trade marketeers – all of which is to say that if agrarian restructuring has taken on global dimensions, it is riddled with unevenness and inequalities (and here claims that the agrarian question is ‘dead’ appear rather curious). The rules of the game may be changing, but the WTO playing field is tilted heavily in favour of the OECD sponsors of this neo-liberal spectacle.

Bobrow-Strain (2007).

agribusiness A term coined by economists Davis and Goldberg (1957, p. 3) at the Harvard Business School, who defined it as the sum total of all operations involved in the manufacture and distribution of farm supplies; production operations on the farm; storage; processing and distribution of farm commodities and items made from them.

The term emphasizes the increasingly systemic character of food production, in which the activities of farming are integrated into a much larger industrial complex, including the manufacture and marketing of technological inputs and of processed food products, under highly concentrated forms of corporate ownership and management. Agribusiness has since become used in much looser and more ideologically loaded ways as shorthand, on the Left, for the domination of capitalist corporations in the agro-food industry and, on the Right, for the role of in the modernization of food production capacities and practices. In this looser sense it has become a synonym of the industrialization of the agro-food system.

The classic model of agribusiness centres on the vertical integration of all stages in the food production process, in which the manufacture and marketing of technological farm inputs, farming and food processing are controlled by a single agro-food corporation. This model was based largely on the US experience, where corporations such as Cargill and Tenneco gained control of particular commodity chains through a combination of direct investment, subsidiary companies and contracting relationships. Numerous studies in the 1970s drew attention to its
significant for commodities such as fresh fruit and vegetables, broiler chickens and sugar cane (e.g. Friedland et al., 1981). It should be noted that a rival term, ‘la complexe agro-alimentaire’, coined contemporaneously in the French research literature, proposed a much more diffuse model of the industrial development of the agro-food complex (e.g. Allaire and Boyer, 1995).

The ‘US school’ of agribusiness research had considerable influence over the development of AGRICULTURAL GEOGRAPHY in the English-speaking world, particularly in the 1980s. But it has increasingly attracted criticism both because of a disenchantment with its theoretical debt to systems theory, and because vertical integration proved too empirically specific to support the larger claims of agribusiness as a general model of food production today (Whatmore, 2002b).

**AGRICULTURAL GEOGRAPHY**

In the second half of the twentieth century, agricultural geography has undergone profound changes, as has its subject. Until the 1950s, agricultural geography was a subset of ECONOMIC GEOGRAPHY, concerned with the spatial distribution of agricultural activity and focusing on variations and changes in the pattern of agricultural land use and their classification at a variety of scales (see also FARMING). As the economic significance of agriculture declined in terms of the sector’s contribution to GDP and employment, particularly in advanced industrial countries, so interest in the subject diminished in the geographical research community. Thus, by the end of the 1980s, leading practitioners were advocating the end of agricultural geography and the dawn of a ‘geography of food’ (see also FOOD, GEOGRAPHY OF).

The importation of new theoretical concepts from POLITICAL ECONOMY and a shift in the substantive focus of study to the AGRO-FOOD SYSTEM as a whole, rather than farming as a self-contained activity, renewed the field of agricultural geography. Research agendas framed in terms of the agro-food system (see, e.g., Marsden, Munton, Whatmore and Little, 1986), set the parameters for a new phase of geographical interest; the initial momentum for the shift came from encounters with interdisciplinary networks and ideas, notably those of rural sociology, as much as with conversations with the broader geographical community.

By the early 1990s, researchers had taken the field beyond the farm gate in two directions. First, it had expanded to the wider organization of CAPITAL ACCUMULATION in the agricultural and food industries, focusing on the social, economic and technological ties between three sets of industrial activities: food raising (i.e. farming), agricultural technology products and services, and food processing and retailing. Second, it now encompassed the regulatory INFRASTRUCTURE underpinning these activities, focusing on the political and policy processes by which national and supranational state agencies intervene in agricultural practices and food markets.

The contemporary agro-food system is a composite of these various perspectives and concepts (see Millstone and Lang, 2003), as depicted in the accompanying figure. The figure illustrates the enlargement of the scope of agricultural geography from a focus primarily on activities taking place on the farm itself (B) to one spanning the diverse sites and activities of food production and consumption (A–D). In addition to emulating economic geography’s enduring emphasis on TRANSNATIONAL CORPORATIONS, this broadening focus of agricultural geography includes particular attention to the regulatory agencies and processes that are so prominent in the organization of advanced industrial food production and consumption (see Marsden, Munton, Whatmore and Little, 2000).

Research within this political economy tradition has been driven by two contradictory impulses. On the one hand, it has sought to treat agriculture and food production as just another industrial sector, like cars or steel, thus aligning it much more closely with the broader community of INDUSTRIAL GEOGRAPHY and its concerns with GLOBALIZATION, corporate CAPITALISM and the so-called transition from FORDISM to POST-FORDISM. Indeed, many concerns associated with the AGRARIAN QUESTION, such as the uneven process of capitalist development, came to preoccupy industrial geographers in the past decade. On the other hand, researchers have sought to make sense of the distinctive features of the industrial organization of farming that persist, particularly the adaptive resilience of family and PEASANT forms of production (e.g. Whatmore, 1991; Watts, 1994a), and their intimate relationship with rural LANDSCAPES and national historiographies, which magnifies their political significance in the electoral and policy processes of developed and developing countries to this day (e.g. Moore, 2005).

HOUSEHOLD LABOUR (domestic food preparation)

agricultural geography (reproduced from Whatmore, 2002a, p. 13)
The tensions between these two impulses have proved potentially creative, and geographers’ efforts to recognize and work through them have been a major contribution to the interdisciplinary field of agro-food studies. These efforts bring quite different levels of analysis into common focus to examine the social and economic connections between, for example, global and local networks, corporate and household actors, production and consumption processes. The influential collection of essays *Globalising food*, edited by David Goodman and Michael Watts (1997), exemplifies these contributions. But, as this same volume indicates, the tensions between the two impulses in agricultural geography have also generated some significant analytical disagreements and silences, including a growing divergence between North American and European agro-food research in terms of theoretical influences, analytical foci and policy engagement. Crudely put, the divergences revolve around the extent to which the social, political and cultural diversity of food production and consumption processes are admitted into the compass and terms of analysis.

However, there is arguably a more widely shared sense emerging among geographers and others about the need to direct attention to (at least) three critical issues that have been eclipsed and/or marginalized by the terms of political economic analysis. First, there is the question of ‘nature’ and farming’s impact on valued environments, culminating in the reorientation of agricultural subsidies (notably the European Common Agricultural Policy) towards the promotion of environmental rather than productivity outcomes (Lowe, Clark, Seymour and Ward, 1998). Second, there is the rise of consumption as a key focus of analysis, not least in the political significance of consumer anxieties around industrial agriculture associated with a series of ‘food scares’ (Friedberg, 2004). Linking these two themes is a growing interest in so-called ‘alternative food networks’ or ‘quality foods’ such as fair-trade, organic and animal welfare foods. Here, attention focuses on the bodily currency of agro-food networks as they connect the health and well-being of people (both as food consumers or producers), the animals and plants that become human foodstuffs, and the ecologies that they inhabit (Stassart and Whatmore, 2003).

**Agricultural involution**  A term coined by the anthropologist Clifford Geertz (1963) to refer to the intensification and elaboration of the agrarian labour process without substantial gains in per capita output. Based on his studies of rice paddy production in post-colonial Java and concerned with prospects for development, Geertz posited that rice production there hindered the modernization process. Without the application of new methods, it absorbed virtually all existing labour, so that productivity merely kept up with population growth. His thesis can be contrasted with the Boserup thesis (Boserup, 1965), which sees population growth as inducing technological change. (See also intensive agriculture.)

Harriss (1982).

**Agricultural Revolution**  A collection of social, technological and productivity changes, which took place somewhere between the sixteenth and the nineteenth centuries, and which collectively revolutionized English agriculture. These changes are generally associated with the industrial revolution and are widely thought to have promoted industrialization, both by reducing agriculture’s share of the workforce and by enabling a much larger population to be fed. The same term is also sometimes used to describe similar agricultural changes in Scotland and Wales in the eighteenth and nineteenth centuries, as well as in Continental Europe in the nineteenth century. Whilst there is general agreement amongst historians and historical geographers that an Agricultural Revolution took place in England, there is profound disagreement both as to when and where it took place, and as to what it entailed.

Writers on the Agricultural Revolution have drawn attention to one or more of three major areas of change (Overton, 1996):

1. A change in the social organization of agriculture, usually described as a shift from peasant agriculture to agrarian capitalism, a process sometimes termed an ‘agrarian revolution’. This process had two central features. First, there was a long-term shift away from production for use to production for sale; such commercialization clearly began in the medieval period and may have been essentially completed before 1700. Second, there was a shift away from the...
dominance of small farms worked mainly by family labour to a system whereby most land was owned by large estates, let as large farms at commercial rents to capitalist tenant farmers and worked by wage labour. Both the chronology and causes of this second shift have been the subject of much debate. There is no agreement over whether the key period of change was the sixteenth, seventeenth or eighteenth century, but the primacy once accorded to ENCLOSURE is now usually displaced by causes such as population change and long-term price movements.

(2) Technical changes, particularly in the eighteenth and nineteenth centuries, have loomed large in accounts of the Agricultural Revolution. In the arable sector, the key innovation was the introduction of more complex crop rotations including clover and turnips, which provided high-quality fodder for animals, thus allowing the area of grassland to be reduced without decreasing the production of animal products. It now seems clear that these and associated changes allowed an extension of the arable area between 1750 and 1850 (Campbell and Overton, 1993; Williamson, 2002). In the pastoral sector, technical improvements were related largely to selective animal breeding aimed at increasing carcass weight, decreasing the age at maturity (slaughter) for meat animals or increasing the yields of wool or milk.

(3) Until recently, discussions of agrarian change were not informed by any direct accounts of productivity, but measurements of changes in productivity and their connection with technical change have since been placed on a more secure statistical footing (Wrigley, 1985a; Allen, 1992, 1999; Overton, 1996).

In the early twentieth century, the historiographical emphasis was on technical and social change, and the most important changes were held to have taken place in the late eighteenth and early nineteenth centuries, in parallel with what was then thought to be the key period of industrialization. Chambers and Mingay’s classic (1966) account more or less repeated this framework, but its restatement coincided with a series of major revisions: Jones (1965) identified the century from 1650 to 1750 as the key period, while Kerridge (1967) argued that the Agricultural Revolution’s key achievements were between 1570 and 1673. The debates have multiplied ever since.

Although recent work has generally focused on productivity, different measures of productivity have been emphasized. Wrigley (1985a) has stressed the growth of labour productivity between 1550 and 1850, and the way in which that allowed a wider restructuring of the economy through a shift in occupational structure away from agriculture towards manufacturing and services. Grain yields are known to have doubled between 1500 and 1800. Allen (1992; cf. Glennie, 1991) put the growth in wheat yields in the seventeenth century at centre stage, and in his subsequent (1999) account emphasized the growth in total food output between 1600 and 1750 and between 1800 and 1850, as well as the growth of wheat yields. Overton (1996) has emphasized three features of the century after 1750: the unprecedented increase in total food production implied by the tripling of population over any previously achieved level, a rise in overall grain yields, and the fact that these productivity changes coincided with a period of fundamental technical change. Turner, Beckett and Afton (2001) have argued that the key changes took place between 1800 and 1850, though they pay no attention to the undoubted achievements of the period before 1700.

A series of major and historically unprecedented achievements can be identified in English agriculture for every identified sub-period between 1550 and 1850, therefore, and it is probably unhelpful to isolate one particular element and identify the period of its achievement as ‘the Agricultural Revolution’. Such a broad perspective sits comfortably alongside recent views of industrialization as a process that began well before 1750.

agro-food system According to the Organisation for Economic Co-operation and Development (OECD), ‘the set of activities and relationships that interact to determine what, how much, by what methods and for whom food is produced and distributed’ (Whatmore, 2002b, pp. 57–8). The most commonly acknowledged sectors/spheres that comprise the agro-food system are agrarian production itself (FARMING); agricultural science and technology products and services to farming (upstream industries); food processing, marketing, distribution and retail (downstream industries); and household food purchasing, preparation and
CONSUMPTION. In addition, those state and, increasingly, private bodies that regulate prices, terms of trade, food quality and environmental concerns relative to food production play an integral role in shaping the agro-food system. Various analytical frameworks have been employed to specify the ways in which the multiple practices and institutions that organize the provision of food are interrelated, and even co-produced.

Among different conceptualizations of the agro-food system, one major axis of difference is whether the key organizing forces of the food system exist at horizontal scales or vertical flows. An example of the first is the concept of food regime. Borrowing from regulation theory, Friedman and McMichael (1989) first employed this concept to denote the existence of national patterns of food production and trade that are periodically stabilized by distinct configurations of private, sub-national, national and supra-national regulation. An example of the latter is Fine, Heasman and Wright’s (1996) ‘system of provision’. In keeping with the commodity chain approach, they take the vertical trajectory of a given commodity as the unit of analysis. In this approach, the agro-food system is best understood as a composite of all commodity systems, even though many food stuffs travel through horizontal organizations and institutions and are eaten as part of a (horizontal) diet.

A second major consideration in these differing approaches is the extent to which the natural conditions of production, the organic properties of food, and/or specific commodity characteristics are seen to shape the agro-food system. Goodman, Sorj and Wilkinson (1987) afford a good deal of explanatory power to the biological foundations of food production insofar as they posit that industrialization takes place in ways that are distinct from other key sectors (see agrarian question).

A third consideration is the ontological status of the food system itself; namely, to what extent the term reifies a set of relationships that are then seen to be more determined and stable than they may be. Drawing on French convention theory, Allaire and Boyes (1995) first highlighted the importance of embedded social relations in constructing the quality of food commodities. Recently, agro-food scholars have borrowed from actor-network theory as well, not only to recognize that food provision is more contingent, variable, fragmented and, hence, vulnerable to political change than the systemic language implies, but also to theorize the significance of the non-human in non-binary ways. Whatmore and Thorne’s (1997) discussion of alternative food networks mostly precipitated the shift from ‘systems’ to ‘networks’ as the dominant analytic in agro-food studies.

aid Targeted and typically conditional flows of resources aimed at alleviating specific social and economic problems and/or promoting long-term economic development. Aid may take a variety of forms, but the predominant forms, such as World Bank loans and Official Development Assistance (ODA) from government agencies, are usually designed to encourage specific policy choices by recipients and are conditional upon the recipient importing specific products or services from firms connected with the donor agency.

Such forms of ‘tied aid’ have a long history, but have become especially important since the end of the Second World War. From that point the World Bank, which was formed along with the International Monetary Fund (IMF) in 1945, took on a central role in providing large-scale international aid for reconstruction and long-term development (Payer, 1982; Kolko, 1988, pp. 265–77). While the World Bank was originally focused upon the reconstruction of advanced industrial economies, it came later to have as one of its main tasks the provision of aid to developing countries. Since the 1970s, World Bank loans have been offered on the condition that a number of political and economic reforms, often referred to as ‘structural adjustment’, are implemented (Mosley, Harrigan and Toye, 1991; see also neo-liberalism). This practice has come under considerable criticism in recent years, on grounds ranging from distributional and environmental impacts to failure to involve local communities in development decisions.

Many forms of ODA have been criticized, like World Bank projects, for their effects on local livelihoods and recipient country autonomy (Gibson, Andersson, Ostrom and Shivakumar, 2005). For example, tied aid forces recipient countries to purchase goods and services from the donor country, thus subsidizing donor country exporters and forcing recipients to purchase goods.

For example, in 1990, only one of the world’s 27 Development Assistance Countries (DAC),
Norway, gave more than 1 per cent of its Gross National Income (GNI) in aid (1.17 per cent), with the DAC average being 0.33 per cent of GNI. In 2003, no DAC members donated as much as 1 per cent of GNI, and the overall DAC average declined to a quarter of one per cent. For the USA, the figures were 0.21 per cent in 1990 and 0.15 per cent in 2003 (UNDP, 2005, p. 278). Other forms of emergency and short-term relief aid are provided under the auspices of a wide variety of agencies, including humanitarian and non-governmental organizations. With an endowment of nearly $40 billion in 2008, the Bill and Melinda Gates Foundation is set to become a major player among international aid agencies.

AIDS Geographical perspectives on Acquired Immune Deficiency Syndrome, its causes and consequences, have taken three related tacks. The earliest was from the discipline’s spatial science tradition (e.g. Shannon, Pyle and Bashshur, 1991). This approach treated AIDS as a newcomer in a long line of non-human infective agents (bacteria, viruses etc.), such as cholera, influenza, tuberculosis and malaria, that medical geographers could model (see medical geography). Work in this tack mapped the spatial distribution, and sought to model the diffusion of the disease (especially its various strains) predictively.

This approach was quickly outpaced by political and cultural geographers, who exposed the homophobia and heterosexism often at work in earlier spatial science approaches, as well as reflecting a postmodern trend that challenged the primacy of science to guide geographers’ approach to studying the world. (For instance, this work often exposed spatial science’s embarrassingly awkward encounters with culture.) Rather than reductively conceptualizing the virus as a non-human/biological entity (as spatial science had), this scholarship emphasized the virus and its syndrome as a thoroughly social, rather than biological, phenomenon. It therefore explored the multiple meanings at stake in transmission, prevention and care. It showed how various structures such as patriarchy, biomedical hegemony and racism, in places disempower people living with HIV. It especially reframed AIDS as a political geography, raising questions of equity and social justice in particular places. In this way, HIV-positive people were reconceptualized not as passive nodes of diffusion (with all the attendant blame), but as active agents struggling to prevent further infection, and to respond caringly and humanely to the ‘glocal’ dimensions (see globalization/glocality) of the pandemic. In this way, geographers’ complex response to AIDS was a synecdoche for the epistemological and methodological debates within/between medical geography and geographies of health and health care, but also the growing interest in feminism and the rise of queer geography (see queer theory). It thereby accelerated and intensified links between that sub-discipline and a wide array of others. This work also broached the nature–society duality, exemplifying for some the incorporation of the body and disease into the exploding field of political ecology.

Presently, work in geography continues on the social construction of the syndrome and the various social identities of sexuality, race, class and gender (e.g. Raimondo, 2005). In more contemporary work on HIV and AIDS, there has also been a return to a more global (or glocal) perspective (Craddock, 2000b). There has also been a much needed return to a regional focus on AIDS in Africa (e.g. Oppong, 1998; Kesby, 1999), but also the global South more generally, bringing the pandemic into development geography, as well as globalization and geographies of neo-liberalism (e.g. questions on access to expensive, life-saving drugs in the context of free trade and market hegemony; or questions of safer-sex education in the context of an ascendant social conservatism and homophobia in social and international aid policy). In this way, more recent works show a much greater appreciation of the multiplicity of social geographies of AIDS than the previous two strands of research.

Algorithm A problem-solving procedure with set rules. Many algorithms can be represented as decision-making trees and translated into computer code, allowing complex tasks to be tackled efficiently.

Alienation A term derived from the Latin word *alienus*, meaning ‘of or belonging to another’. Of Judeo-Christian origin, the concept
became a secularized keyword in nineteenth- and twentieth-century PHILOSOPHY and SOCIAL THEORY via G.W.F. Hegel's writings, particularly his *Phenomenology of the spirit* (1808) and *Philosophy of right* (1821), and their critical adaptation by Karl Marx in his early writings (1843–5). In *Phenomenology*, Hegel contended that the object world (NATURE, RELIGION, ART etc.), which loomed independent of man's consciousness, epitomized alienation. Accordingly, absolute knowledge or freedom consisted in overcoming alienation by understanding the external world as emanation of Spirit – a facet of the human subject's own self-consciousness or essence. Rejecting the politically conservative implications of Hegel's philosophy, which anointed the STATE and its order of private property as the culmination of substantive freedom (i.e. as the essence and end product of man's striving for self-consciousness), Karl Marx instead proposed that capitalist production organized around state-protected private property rights and that calculative reason was the source of radical disharmony among individuals, who ended up estranged from their social existence; between individuals and their creative life activity or labour; and between individuals and means of production (see CAPITALISM; CLASS). The concept of alienation entered geography via the work of Bertell Ollman (1976) and his interlocutors.

**Alonso model** A model of the zonal structuring of land use within an urban area. Using ACCESSIBILITY (measured as transport time and cost: cf. FRICION OF DISTANCE) as the key variable, it accounts for intra-urban variations in land values, land use and land-use intensity. Its simplest form assumes that all journeys are focused on the city centre. Land users balance transport costs to that point against those for land and property, with the highest prices being bid for the most accessible inner-city land – which only commercial and industrial enterprises can afford. The result (shown in the figure) is a DISTANCE-DECAY relationship between location-rent and distance from the centre, with residential uses (which have the lowest BID-RENT CURVES) confined to the outer zone. Alonso's now largely obsolete model of a unicentric city can be modified to accommodate a multi-centred organization of urban land use (see CENTRIFUGAL AND CENTRIPETAL FORCES; DECENTRALIZATION; EDGE CITY; CENTRAL BUSINESS DISTRICT).
SPRAWL) and also GENTRIFICATION of inner-city, formerly non-residential areas, but is less relevant to spatial structures in which accessibility to a small number of points (usually by public transport) is a minor influence on many locational choices.

alterity A philosophical term for OTHERNESS. Rather than referring to individual differences, it more often refers to the systematic construction of classes, groups and categories. Such groups or classes are seen as ‘Other’ to a dominant construction of the Self (Taussig, 1993). Occupying the position of outsiders, such groups are often denied the basic RIGHTS and dignities afforded to those who are included within such cultural units as COMMUNITY, CITIZENSHIP or humanity (Isin, 2002). Alterity does not refer merely to a casting out. Instead, the logic of exclusion is such that the Other is immanent to the constitution of the dominant group.

alternative economies Approaches to TRADE that challenge many of the principles of CAPITALISM. As part of a broader set of critical commentaries on capitalism (see, e.g., Gibson-Graham, 1996), work on alternative economies has revealed the importance of initiatives including gift economies, charity banks and Local Exchange Trading Systems (see Leyshon, Lee and Williams, 2003). Alternative economies are often seen as a viable strategy for dealing with forms of social exclusion caused by groups being bypassed or exploited by mainstream spaces of capitalism, such as the retail banking industry (Leyshon, Burton, Knights, Alferoff and Signoretta 2004).

America(s) (idea of) The landmass in the Western Hemisphere consisting of the continents of North and South America (sometimes Central America and the Caribbean are identified as separate sub-regions). The plural form is relatively recent, providing an alternative to a singular that typically refers to either the entire landmass or the United States of America on its own. The earliest use of the name America for the continents of the Americas is on a globe and map created by the cartographer Martin Waldseemüller in 1507. The most popular story about the naming draws from a book that accompanied the map in which the name is derived from the Latin version of the explorer Amerigo Vespucci’s name, Americus Vespucius, in its feminine form, America, as all of the continents were given Latin feminine names by their European namers. From this viewpoint, Vespucci (directly or indirectly) ‘invented’ America (O’Gorman, 1961).

Most of the inhabitants of the Americas call themselves Americans, but in the English-speaking world use of the word is often restricted to residents of the USA, a product both of the difficulty of making ‘the United States’ into an adjective and the political–economic weight of the USA. The majority of the population of the Americas lives in LATIN AMERICA (542 out of 851 million), named as such because the south and central regions were colonized mainly by Spain and Portugal, in distinction from North America colonized initially by the British and French. As the largest and most developed economy, the USA has long dominated economically and frequently manipulated politically the states and peoples in the rest of the landmass.

The discovery of America by Europeans is usually put down to Christopher Columbus in 1492, though the existence of lands to the west of Europe was mooted in medieval Europe. Effectively, however, in terms of political, economic and intellectual consequences, it is the European encounter after 1492 that is most significant, even though it was not until the late eighteenth century that the shape of the landmass as a whole was finally established. The appearance of America in the mental universe of fifteenth-century Europeans represented a crucial early moment in the creation of the sense of a geopolitical world (see geopolitics) that was increasingly to match the physical Earth. The ‘discovery’ was more than just the discovery of a new RACE of non-Europeans. More particularly, it was the discovery of a previously unknown landmass and with it the recognition that ancient Greek cosmology, which had divided the Earth into three parts, had been mistaken (Kupperman, 1995).

Initially, at least, as John Elliott (1972) has argued, the discovery of America encouraged European intellectuals and officials to enlarge their concept of humanity. Eventually, though, the new variety of patterns of human
behaviour made for some difficulty in retaining the natural law belief in an essential and universal human nature. The increasing sense of absolute cultural difference from the natives and the impulse to exploit the new-found lands of America combined, however, to create propitious circumstances for the expansion of settlement by Europeans. To the English philosopher John Locke, writing in 1689 and providing an early example of the backward-modern conception of the stages of human social development, the Roman law known as res nullius applied to the ‘empty lands’ not put to active agricultural use by the native inhabitants and thus justified their takeover: ‘America’, he wrote, ‘is still a pattern of the first Ages in Asia and Europe, whilst the Inhabitants were too few for the Country, and want of People and Money gave Men no temptation to enlarge their Possessions of Land, or contest for wider extent of Grounds’ (Locke, 1960 [1689], pp. 357–8; see also TERRA NULLIUS).

America was EUROPE’s first ‘new world’. As such, it was regarded as a tabula rasa for European efforts at bringing the whole world into the European world economy (Armitage, 2004). In this respect, North and South America parted company over how this was done. If from 1492 to 1776 the North was increasingly dominated by an EMPIRE in ascendance, the British, the South was subject to two empires, those of Spain and Portugal, in long-term decay. By the late eighteenth century, local settler elites in both parts were in revolt against distant rule. As a result of their relative success, they were able by the early nineteenth century to imagine an America autonomous of Europe in which their ‘political independence was accompanied by a symbolic independence in the geopolitical imagination’ (Mignolo, 2000, p. 135). If on the US side this led to the Monroe Doctrine of ‘America for the Americans’, on the southern side it led to a developing sense of a ‘Latin America’ increasingly dominated by its northern neighbour, particularly as the USA emerged as a global power towards the century’s end. The struggle to expropriate or qualify the labels ‘America’ and ‘American’, therefore, cannot be separated from the wider political conflict over the geopolitical consequences for the whole world of the discovery and subsequent rising significance of the ‘Americas’.

**American empire** As an informal form of imperial rule mediated by market mechanisms as much as by military might, American EMPIRE has traditionally proved to be an elusive object of analysis and critique (but see Williams, 1980). In the context of the Iraq war this elusiveness has declined, afflicted by the spectacle of US dominance and the protests ranged against it (RETORT, 2005). In the media, liberal apologists joined conservatives in promoting the Iraq adventure explicitly as a way of expanding American empire (e.g. Boot, 2003; Ignatieff, 2003), and, in the streets, amongst the millions marching against the war in 2003, many held placards that just as explicitly decried the violence and hubris of empire. However, as the playwright Harold Pinter reminded audiences when he received his Nobel Prize in 2005, the norm has more generally been silence on the topic. ‘The crimes of the United States have been systematic, constant, vicious, remorseless,’ he complained, ‘but very few people have actually talked about them’ (Pinter, 2005). One explanation for this silence is that in political DISCOURSE two kinds of ‘exceptionalism’ continually conspire to make talk of American empire somehow seem inappropriate. On the one hand, there is the exceptionalism of imperial denial that developed out of the anti-imperial origins of American CAPITALISM and the Jeffersonian idea of the USA as an ‘empire of liberty’. Having started with the national origin stories about independence from imperial rule, this is the popular discourse that extends today to arguments that American dominance in the MIDDLE EAST is exceptional in its emphasis on freedom, free enterprise and liberal rights. On the other hand, there is the illiberal connotation that makes exceptions in the name of American ‘leadership’ or ‘sovereignty’: a discourse that argues that unique global circumstances require the USA to make exceptions and break global rules (such as the Geneva Conventions) in order to maintain global order. There is a wealth of scholarship addressing how the contradiction between these two discourses exposes the exclusions and obscured authoritarian underpinnings of liberal universalism (Cooper, 2004; Lott, 2006; Singh, 2006). By also mapping the geographies of dominance that are at once concealed and enabled by the appeals to exceptionalism, CRITICAL HUMAN GEOGRAPHY has simultaneously sought to make American empire itself less obscure (see El Fisgón, 2004).

Challenging the liberal capitalist dissembling of empire, Neil Smith has underlined
how the exceptionalist RHETORICS of imperial denial have also been predicated on a form of flat-world disavowal of geography (Smith, 2003c, 2005b; see also Sparke, 2005). By promoting the US model of liberal-democratic capitalism in the terms of an ‘American Century’ (as Henry Luce, the publisher of Time magazine, did in 1941) and by recently attempting to renew and expand this world historical dominance with a ‘Project for a New American Century’ (as neo-conservative advocates of a FAX AMERICANA have done in the past decade), Smith argues that a focus on making global history has helped to hide the global geography of American empire. Advanced today with a geographical appeals to GLOBALIZATION, Smith suggests that American dominance abroad is also ironically vulnerable to nationalist reaction at home (cf. Pieterse, 2004). Focusing further on the capitalist contradictions in the global system on which these vulnerabilities turn, other geographers have emphasized that American global Hegemony has been centrally related to the country’s role as the incubator, exporter and regulator of free-market neo-LIBERALISM on the world stage (Harvey, 2004b, 2005; Agnew, 2005a). Such work suggests that just as this hegemony was underpinned by America’s centrality to twentieth-century capitalism, so too will it be undermined by the changing economic organization of the world, including the USA’s increasing indebtedness in the twenty-first century.

While the political-economic geography of globalization exposes forms of American dominance that lie beneath the flat appeals of liberal exceptionalism, cultural-political geographies of American empire have in turn showed how the illiberal exceptionalism illustrated by America’s contravention of laws protecting liberty has also created spaces of exception (see EXCEPTION, SPACE OF) on the ground. Derek Gregory’s account of the ‘colonial present’ thus explores how imaginative geographies tied to ORIENTALISM have helped to legitimize the US-led re-colonization of the Middle East, turning the local inhabitants into outcasts and depriving them of human rights in the name of spreading freedom (Gregory, 2004b; see also Mitchell, 2002; Vitalis, 2002). Similarly, recent work by the American intellectual historian Amy Kaplan has provided a scrupulous legal geography of the Guantánamo military base as another space of exception that is at once inside and outside the empire of American liberty (Kaplan, 2005; see also Gregory, 2006).

Pinter the playwright argued that the double standards represented by such spaces are normally hidden backstage: ‘you have to hand it to America,’ he concluded. ‘It has exercised a quite clinical manipulation of power worldwide while masquerading as a force for universal good. It’s a brilliant, even witty, highly successful act of hypnosis.’ But what comes after the wit and hypnosis when the whole world can see the torture and abuse that go on backstage? One answer is simply the end of empire, or, as the RETORT group put it, ‘real strategic failure’ (RETORT, 2005, p. 5). But before this happens another development, indicated by the work of Gregory, Kaplan and a host of other scholars examining American geopolitics, is an almost religious re-mapping of American grand strategy as a Manichean double vision: a world in which core capitalist countries are seen as deserving of universal RIGHTS while a supposedly dysfunctional set of exceptional spaces are seen as sites where freedom must be suspended and people dispossessed in the name of spreading freedom (see Roberts, Secor and Sparke, 2003; Sparke, 2005; Dalby, 2006; Smith, 2006b). Following this neo-liberal geopolitical script— which has a precedent in imperial British liberalism (Mehta, 1999) —American empire can continue the hypnotic ‘god-trick’ of universalism in the spaces of the core by masquerading as an overarching force for good.

**analogue** The world is too complex to represent in its entirety. Analogue MAPS or other devices produce scaled-down MODELS of the world using lines and areas to represent selected features. This is different from digital models (cf. DIGITAL CARTOGRAPHY), which can be edited and transformed using GIS and other computer programs. In analogue maps or diagrams, for instance, information is fixed. The data cannot be viewed through a different MAP PROJECTION, nor can the SCALE be changed. Analogue maps literally use analogies (lines for roads, blocks for houses, circles for towns, etc.) to represent the Earth. By contrast, digital maps display information on the screen but the properties, such as scale and projection, are not fixed and can be displayed in different formats.

**analytical Marxism** Scholarship using the logic and language of mathematics to interrogate Karl Marx’s theory of CAPITALISM (and other MODES OF PRODUCTION) for theoretical and/or empirical analysis (see MARXISM). In the three volumes of Capital, Marx drew
at times extensively on mathematical examples to explicate his theory of value, as well as on quantitative information about poverty and capital–labour relations in nineteenth-century Britain. Marx has been criticized by mainstream economists for mathematical incompetence, particularly for errors in his ‘transformation problem’, which sought somewhat unsuccessfully to show that prices of production (long-run market prices) are determined by labour values. Sraffa (1960) demonstrated, however, that neo-classical macroeconomics had the same mathematical limitations, being only logically correct if production technologies are identical in every sector of the economy. Morishima showed that Marx’s theory of exploitation can be deduced mathematically from his theory of capitalism: capitalists can only make positive monetary profits if labour is exploited in labour value terms. This triggered scholarship in analytical Marxism.

In economics and sociology, analytical Marxism stressed developing deductive theories consistent with Marx’s theorization of capitalism. Much of this work, pioneered by John Roemer, John Elster, George Cohen and Erik Olin Wright, is grounded in rational choice theory – the belief that macro-features of society are the consequence of the self-interested actions of informed, rational economic actors. Taking the same starting point as neo-classical economics, remarkably they show that under Marxist assumptions a very different view of capitalism emerges. Exploitation occurs, the opposed economic interests of workers and capitalists generate class struggle over the economic surplus, capitalism is unstable, and individuals choose to join exploiting and exploited classes because of initial wealth and endowment differences. These scholars have rejected Marx’s labour theory of value. Empirically, however, observed long-term market prices are indeed closely correlated with labour values, suggesting that such rejection is premature. These rational choice Marxists are criticized for their grounding in rational choice behaviour, and insistence on deductive reasoning, which are seen as inconsistent with Marx’s dialectical logic (see dialectic: see also Roemer, 1982, 1986b; Carver and Thomas, 1995).

Geographers have applied mathematical reasoning to a Marxist analysis of the capitalist space-economy, without grounding this in individual rational choice. Like Harvey’s dialectical analysis, Sheppard and Barnes (1990) demonstrate that the incorporation of space complicates some of Marx’s theoretical propositions. Space further destabilizes the capitalist dynamics of uneven development, increases the likelihood that the interests of individual capitalists are in conflict with class interests and catalyses conflict between places that can undermine class dynamics. Equilibrium analysis is thus of little value, as equilibria are most unlikely and always unstable. Unlike Harvey, it is deduced that space undermines labour value as the foundation of Marxian analysis. Empirically, Webber and Rigby (1996) show that Fordism was not the golden age of postwar capitalism, contra regulation theory. Recent advances in complexity theory suggest that mathematical analysis of complex systems such as capitalism approximates many aspects of dialectical reasoning, suggesting that Marx’s own resort to mathematics was not in tension with his philosophical approach.

anarchism A political philosophy that is anti-authoritarian, seeking the elimination of the state and its replacement by a decentralized social and political self-governing social order. Anarchist social order is not the absence of government, but a form of self-government that does not demand obedience. It is a mixture of libertarian, utopian and socialist ideas that counters power and hierarchy through voluntary, and usually local, decentralized communities. Cook (1990) identified five different forms of anarchism – individualism, collectivism, anarchist communism, anarcho-syndicalism and pacifism. Anarcho-feminism and situationism are also relevant varieties of anarchism that have been utilized by geographers. Geographers Peter Kropotkin and Elisée Reclus were among the early proponents of anarchist communism. Both were active members of the academic geography community in the late 1800s and early 1900s (Kearns, 2004), though their political leanings were ignored as ‘baggage’ by the geography establishment, which was focused upon imperial and national projects (MacLaughlin, 1986). Kropotkin’s belief that ‘the duty of socially-concerned scientists lay in articulating the interests of subordinate social classes and combating poverty, underdevelopment and social justice’ (quoted in MacLaughlin, 1986, p. 25) lay at the heart of the radical geography that emerged in the late 1970s. However, the initial identification of anarchism as a
ANDEOCENTRICITY

philosophical basis for radical geography was short-lived, and in the late 1970s its influence declined (Peet, 1977b; Peet and Thrift, 1989). More recently, Blunt and Wills’ (2000) identification of radical geography’s attention to anarchism as facilitating the ‘breakthrough’ to MARXISM echoes Peet’s sentiments, but they also highlight Emma Goldman’s contribution to anarcho-feminism and its role in stimulating FEMINIST GEOGRAPHIES.

However, there has been renewed interest in the philosophy and practice of anarchism in explaining contemporary human geography. Sibley (2001) has identified the importance of anarchist theory in promoting the challenge to binary thinking that has developed into the concept of THIRD SPACE. Bonnett’s (1996) study of SITUATIONISTS (a political force that was particularly active in the 1960s, seeking a ‘new human geography’ by critiquing contemporary URBANISM, PLANNING and architecture) focuses upon the creation of politicized urban spaces as a way of challenging authority. Economic geographers interested in contemporary resistance to neo-liberalist GLOBALIZATION have identified the creation of autonomous geographies that are underpinned by anarchist principles. Chatterton’s (2005) study of workers’ co-operatives in Argentina defines three autonomous geographies: a territorial geography of networked autonomous NEIGHBOURHOODS, a material geography of mutual aid, and a SOCIAL GEOGRAPHY of daily practice and interaction. Following the tension in anarchism between individual freedom and social action, Chatterton shows how the groups try to manage their interaction with the rest of the world while simultaneously creating a network of autonomous places. Taylor (2004a) has taken a more structural approach to anarchism in identifying GLOBAL CITIES as a basis for resisting state power. Blunt and Wills’ claim that anarchist ideas have ‘spawned only the outlines of a tradition of geographical scholarship and there is plenty of scope for further elaboration’ (2000, p. 2) is still true, but there are signs that urban, economic and political geographers find contemporary changes a catalyst for elaboration.

androcentricity Viewing the world from a male perspective. Some feminist theorists view mainstream scholarship or science such as geography as androcentric, in that what is presented as a gender-neutral analysis or method, in practice embodies masculine values and assumptions (e.g. Rose, 1993; see also FEMINIST GEOGRAPHIES). Eichler (1988) outlines six types of androcentricity: male frame of reference; locating men as agents and women as objects; female invisibility; maintaining male over female interests; misogyny; and defending male dominance. She also traces five manifestations of androcentricity in the research process (see MASCULINISM).

Anglocentrism An attitude that unreflectively assumes the superiority of KNOWLEDGE produced in Anglo-American contexts (see also ETHNOCENTRISM; EUROCENTRISM). In contemporary geography it refers to a debate – in particular, within CRITICAL HUMAN GEOGRAPHY – addressing the social and epistemological mechanisms that construct an ‘international’ writing space imbued with Anglo-American HEGEMONY. The debate mostly has been performed at International Conferences of Critical Geography and in commentaries and editorials in ‘international’ journals (e.g. Berg and Kearns, 1998; Minca, 2000; Braun, Vaiou, Yiftachel, Sakho, Chaturvedi, Timar and Minca, 2003; Geoforum, 2004).

This Anglo-American hegemony does not work as an intentional domination of debates, nor is it something to be accepted as inevitable – it is the outcome of a series of POWER-constituting practices. One of these is LANGUAGE. To an increasing extent, English has become the lingua franca of ‘international’ academic (and other) discourses, a practice giving precedence to some while putting ‘others’ in a position where they have to cope with the burden of translation and struggle to communicate thoughts and concepts in an idiom that to them is a secondary skill. This is not only about translation in a literal sense, because no language is a neutral medium; the adoption of any language has a range of cultural and conceptual consequences. The question of language therefore folds into a much broader power–knowledge system, which constitutes geographical writing spaces including Anglophone journals, books, conferences, seminars and so on. In these writing spaces, power and knowledge connect, through the media of language, institutional arrangements and social practices of inclusion/exclusion and through the political economy of international publishing, to produce a ‘centre–periphery’ imaginary with regard to the relationship between
Anglo-American and non-Anglo-American writers. Notwithstanding an increased sensitivity to situated knowledge in contemporary geography, these practices, connected to an implicitly supposed neutrality of concepts and categories, tend to conceal the partiality and local character of Anglo-American theoretical production and reproduce it as ‘unlimited’, ‘universal’ or at least ‘transferable’. The ‘master-subject’ of geographical theory is constructed as Anglo-American, with more inferior subject-positions left open to writers from ‘other’ places. Contributions from outside the Anglophone world are at one level welcome, but the authors tend to be seen, not as theory-producing subjects, but rather as providers of ‘case-studies-from-another-place’. The non-Anglo-American writer is constructed as a mediator or translator, often in a double sense; on the one hand ‘translating’ travelling Anglo-American theory and putting it into use in ‘other’ contexts, and on the other one ‘translating’ the unknown and exotic ‘other’ and making it accessible to the powerful knower in the centre.

Geographical writings based in feminism and post-colonialism have in many ways identified and challenged this power-knowledge system. Even they, however, are not immune from the charges made in the debate. Like any dominant discourse, they have difficulties destabilizing their own power position. But the very existence of the debate can be seen as a promising opening; in particular, to the extent that it is based on common recognition and works against the hegemony from ‘inside’ and ‘outside’ alike.

animals Once of marginal concern to geography, animals, their places, welfare, relationships and spatialities have recently become areas of debate and innovation. Attention has been buoyed by growing social concerns for animals and the, albeit problematic, growth in animal rights literature. Moreover, developments in social theory that have (a) deconstructed the human, exposing the indistinct character of the divides between humans and animals (Agamben, 2002), and (b) reconstructed animals, affording them active roles in constituting their environments, bodies and relationships (see actor-network theory, non-representational theory), have started to unsettle the human of human geography.

While antecedents of this new animal geography certainly existed in cultural ecology and studies of domestication (Tuan, 1984), the most important shift in the place of animals in geography occurred in the 1990s, through a series of innovative papers that aimed to bring the animals back in (Wolch and Emel, 1995, 1998; Philo and Wilbert, 2000). This work covered a range of topics focusing on spaces of exclusion of, and human cohabitation with, animals. One difficulty in this work was to devise means of talking about animals themselves, rather than reducing non-human animals to having bit parts in human history (and thereby inadvertently reproducing the Cartesian and Kantian notions of non-human animals as automata, and as means to human ends). It is here that the work of a whole range of approaches that share something with post-structuralism has been most productive in affording animals their own histories and geographies. The work of anthropologists, particularly that of Tim Ingold, highlighted the similarities between human and non-human animals’ dwelling practices (Ingold, 2000). Deconstruction of the terms ‘human’ and ‘animal’ afforded insights into the role that the singular noun ‘the animal’ has played in what Jacques Derrida has called the sacrificial structure of human supremacy (Derrida, 2003). Finally, work informed by understandings and tracings of the material and cultural associations of human and non-human animals has demonstrated complex histories and geographies of sharing (molecules, viruses, flesh), accommodating, adapting, hostilities and hospitalities (Haraway, 2003). The resulting hybrid forms are multiple, leading not to some undifferentiated human/non-human amalgam, but to worlds wherein non-human and human animals differentiate themselves at the same time as they form close relationships (Whatmore, 2002a).

Annales School An interdisciplinary school of French historians established by Lucien Febvre and Marc Bloch, co-founders in 1929 of the journal Annales d’histoire économique et sociale (now Annales. Économies. Sociétés. Civilisations). The Annales, originally based in Strasbourg (a German city from 1871 to 1918) developed an integrative, synthesizing and distinctively French style of ‘total history’, in opposition to German historical methods. Drawing ideas from sociology,
anthropology and HUMAN GEOGRAPHY, the *Annalistes* insisted that short-term political events must be understood in relation to long-term structural economic, social and environmental change. The writings of Fernand Braudel (1902–85) exemplify this approach, which continues to be significant in both French social science and in the (stylistically very different) transatlantic development of WORLD–SYSTEMS ANALYSIS.

**anthropogeography** A school of HUMAN GEOGRAPHY closely associated with the German geographer Friedrich Ratzel (1844–1904; see Bassin, 1987b). Ratzel had trained in the natural sciences and, like many of his contemporaries, was taken by the ideas of DARWINISM (see also LAMARCKISM). Following an extended visit to the USA, however, it was clear that his imagination had also been captured by anthropology. On the marchlands between the natural sciences and anthropology, he now ‘sought to lay out the conceptual foundations of a new discipline – human geography’ (Livingstone, 1992, p. 198). Its central statement was in the two volumes of his *Anthropogeographie*, published in 1882 and 1891, the first subtitled ‘Geography’s application to history’ and the second ‘The geographical distribution of mankind’. These volumes have to be placed in the context of the contemporary debates within the German intellectual community over the place of the cultural sciences and their relation to the natural sciences (Smith, 1991). Ratzel’s achievement was to put ‘the human’ back into GEOGRAPHY: in his view, the discipline could not be assimilated to the natural sciences but, on the contrary, had to explore the reciprocal relations between ‘CULTURE’ and ‘NATURE’. It also had to set those relations in motion by recognizing the dynamics of spatial formations (notably DIFFUSION and MIGRATION).

Ratzel’s project was thus not ENVIRONMENTAL DETERMINISM, as some commentators have suggested, but it was distinguished by the attempt to elaborate a series of nominally scientific concepts whose significance extended beyond the formalization of an academic discipline. For Ratzel, writing in the middle of what Bassin (1987c) describes as an ‘imperialist frenzy’, the development of a STATE could not be separated from its spatial growth. Natter (2005) is thus surely right to say that Ratzel’s *Anthropogeographie* ‘bleeds into’ his *Politische Geographie*, published in 1897. Indeed, Ratzel himself saw Anthropogeographie as only a preliminary stage in the foundation of ‘the science of POLITICAL GEOGRAPHY’. In his *Politische Geographie*, Ratzel accordingly described the state as ‘a living body which has extended itself over a part of the Earth and has differentiated itself from other bodies which have similarly expanded’. The object of these extensions and expansions was always ‘the conquest of SPACE’, and it was this that became formalized in the concept of LEBENSRaUM (‘living space’): ‘the geographical area within which living organisms develop’. Ratzel was keenly aware of the dangers of organicism, but even so insisted that: ‘Just as the struggle for existence in the plant and animal world always centres about a matter of space, so the conflicts of nations are in great part only struggles for TERRITORY’ (see also GEOPOLITICS).

Wanklyn (1961) treats Lebensraum as ‘a fundamental geographical concept’, and in her eyes Ratzel’s writings were directed primarily towards ‘thinking out the scope and content of biogeography’. This is to understand BIO-GEOGRAPHY in a highly particular way, but there is a more general tradition of biogeographical reflection within human geography that suggests affinities between Ratzel’s Lebensraum, Paul Vidal de la Blache’s genre de vie and the concept of rum (‘room’) developed in Torsten Hägerstrand’s TIME–GEOGRAPHY. If these affinities are recognized, then Dickinson’s (1969) view of Ratzel’s original formulation, stripped of its subsequent distortions by the Third Reich, as ‘one of the most original and fruitful of all concepts in modern geography’, becomes peculiarly prescient. But such a purely ‘scientific’ reading does scant justice to the context in which Ratzel was working and, in particular, ignores the fact that his vision of human geography not only had political implications but also rested on – and indeed was made possible by – a series of political assumptions (Bassin, 1987b). Crucially, Farinelli (2000, p. 951) insists that through Ratzel’s reformulations ‘the state takes possession of geography, and becomes its supreme object’.

Farinelli (2000); Natter (2005).

**anti-development** A body of work and practice that is fundamentally opposed to mainstream conceptions of DEVELOPMENT. Standard accounts of development assume...
that people’s lives will be improved to the extent that they are linked to others by efficient systems of economic production and exchange, and by capable systems of government. Development presumes an extension of scale in social life. With this comes a surrender of power to experts and more abstract social forces such as the financial system or the state. Anti-developmentalist have opposed these notions for several reasons. As early as 1908, Mohandas Gandhi raged against the introduction of manufacturing into India in his essay _Hind Swaraj_ (Gandhi, 1997 [1908]). It was dehumanizing, he said, and removed the possibility of living a virtuous life, which revolved around self-provisioning and religious contemplation in a village setting. There are echoes of this complaint in Tolstoy and Ruskin and other parts of the Western pastoral tradition.

Modern anti-developmentalist continues to draw on Gandhi, but it also draws on more contemporary critiques by Schumacher, Illich, Berry and others. For the Indian public intellectual Ashis Nandy (2003), developmentalism is a violent set of social practices that denies space to other accounts of being human. The violence that Nandy refers to is an originary violence that resides in the will to power that development must embody. By this yardstick, efforts to promote human development or sustainable development are omissive. Development is opposed to humanity and to forms of life lived in harmony with other beings, and hence the call for its negation. Other versions of anti-development strike a more populist note. Development is condemned less for its intrinsic violence – for creating what Esteva and Prakash (1998) call the ‘cold calling-card mentality of the modern West’ – than for its self-satisfied service on behalf of the global rich. In the words of Gustavo Esteva, ‘If you live in Rio or Mexico City, you need to be very rich or very stupid not to notice that development stinks.’

Critics of anti-development believe that it is all but impossible to opt out of some version of development, and/or that some versions of development have empowered poorer people in countries as diverse as Costa Rica, Botswana and Taiwan (Kiely, 1999). Life expectancies in India and China increased by more than twenty-five years over the period from 1950 to 2000, the so-called ‘Age of Development’. If there is room for criticism of ‘the’ development discourse, it needs to be promoted within the framework of post-development, or as a series of alternatives to mainstream conceptions of development.

**anti-globalization** A set of political positions that articulate resistance and alternatives to neo-liberal or capitalist globalization. A range of international initiatives have cohered since the 1970s, such as the international anti-corporate boycott of Nestlé’ between 1977 and 1984, the riots against International Monetary Fund (IMF) Structural Adjustment Programmes throughout the global South during the 1980s and the formation of Via Campesina – an international farmers’ network (Starr, 2005). A key moment was the emergence in 1994 of the Zapatista rebellion in Chiapas, Mexico, which has demanded indigenous rights and the democratization of Mexican civil and political society, as well as articulating both a critique of the globally dominant economic process of neo-liberalism, and a vision of an alternative politics (Routledge, 1998).

The emergence of neo-liberal globalization as the globally hegemonic economic model has prompted the upscaling of previously local struggles – between citizens and governments, international institutions and transnational corporations – to the international level, as marginalized groups and social movements have begun to forge global networks of action and solidarity. ‘Anti-globalization’ is a misnomer, since such groups struggle for inclusive, democratic forms of globalization, using the communicative tools of the global system such as the Internet. What they are expressly against is the neo-liberal form of globalization. Hence a more accurate term is ‘grassroots globalization’ (Appadurai, 2000), although other popular names have included ‘globalization-from-below’ (Brecher, Costello and Smith, 2000), ‘movement of movements’ (Mertes, 2004) and the global justice movement (see www.globaljusticemovement.net).

By taking part in grassroots globalization networks, activists from participant movements and organizations embody their particular places of political, cultural, economic and ecological experience with common concerns, which lead to expanded spatiotemporal horizons of action (Reid and Taylor, 2000). Such coalitions of different interests are necessarily contingent and context-dependent, forms of solidarity being diverse, multiple, productive and contested (Braun and Disch,
Grassroots globalization networks have been manifested in ‘global days of action’, which have consisted of demonstrations and direct actions against targets that symbolize neo-liberal power, such as the G8 (e.g. protests in Genoa, Italy, in 2001 and Gleneagles, Scotland, in 2005), the World Trade Organization (protests in Seattle, USA, in 1999, Cancun, Mexico, in 2003 and Hong Kong in 2005) and the World Bank and the IMF (e.g. protests in Prague, Czech Republic, in 2000 and Washington, USA, in 2002 and 2005). Such protests have been characterized by a convergence of interests and concerns in the particular place of protest, and solidarity protests that have occurred in cities across the globe at the same time. The symbolic force generated by protests in such places has contributed to further mobilizations and the creation of common ground amongst activists.

Another important manifestation has been the establishment in 2001 of the World Social Forum (WSF) – an annual convergence of NGOs, trades unions, social movements and other resistance networks in Porto Alegre, Brazil (2001–3), and subsequently in Mumbai, India (2004). The WSF attempts to engender a process of dialogue and reflection, and the transnational exchange of experiences, ideas, strategies and information concerning grassroots globalization. The WSF (which attracted tens of thousands of participants in 2003) has decentralized into regional and thematic forums that are being held in various parts of the world, such as the European Social Forum in Florence, Italy (2002), the Asian Social Forum in Hyderabad, India (2003), and the Thematic Forum on Drugs, Human Rights and Democracy in Cartagena, Colombia (2003) (Sen, Anand, Escobar and Waterman, 2004).

Mary Kaldor (2003) posits that such developments represent the emergence of a ‘global civil society’ that includes at least six different types of political actor that are ‘anti-globalization’ in outlook: more traditional social movements such as trades unions; more contemporary social movements such as women’s and environmental movements; NGOs such as Amnesty International; transnational civic networks such as the International Rivers Network; ‘new’ nationalist and fundamentalist movements such as Al Qaeda; and the anti-capitalist movement. Meanwhile, Amory Starr (2000) identifies at least three different strategic foci within the ‘anti-globalization movement’: (i) Contestation and Reform, which involves social movements and organizations that seek to impose regulatory limitations on corporations and or governments, or force them to self-regulate, mobilizing existing formal democratic channels of protest (e.g. Human Rights Watch and the Fair Trade network); (ii) Globalization from Below, whereby various social movements and organizations form global alliances around such issues as environmental degradation, the abuse of human rights and labour standards, to make corporations and governments accountable to people instead of elites (e.g. the Zapatistas, labour unions or the WSF); and (iii) De-linking, Relocalization and Sovereignty, whereby varied initiatives articulate the pleasures, productivities and rights of localities and attempt to de-link local economies from corporate-controlled national and international economies (e.g. permaculture initiatives, community currency, community credit organizations, sovereignty movements – especially those of indigenous peoples – and various religious nationalisms; see also Hines, 2000).

Despite such diversity, certain key areas of agreement have emerged, such as demands for (i) the cancellation of foreign debt in the developing world (which amounted to US $3,000 billion in 1999); (ii) the introduction of a tax on international currency transactions, and controls on capital flows; (iii) the reduction in people’s working hours and an end to child labour; (iv) the defence of public services; (v) progressive taxation to finance public services and redistribute wealth and income; (vi) the international adoption of enforceable targets for greenhouse emissions and large-scale investment in renewable energy; (vii) policies that ensure land, water and food sovereignty for peasant and indigenous people; and (viii) the defence of civil liberties (Callinicos, 2003; Fisher and Ponniah, 2003). At the root of such demands is the perceived necessity to reclaim and protect common resources and rights seen as directly under threat of erasure or appropriation by the processes and agents of neoliberal globalization. PR

anti-humanism A critique of humanism that seeks to displace the human subject as the centre of philosophical and social enquiry. Knowledge and understanding, morality and ethics, and interpretation are all challenged by
a rethinking of notions of agency, rationality and subjectivity. While 'anti-humanism' is a term that can encompass a range of different perspectives, it generally takes its philosophical basis from Friedrich Nietzsche's thinking through of the death of God. For Nietzsche, it was not enough to replace God at the centre with the human but, rather, the implications needed to be thought through more fundamentally. Martin Heidegger's 1947 'Letter on Humanism' (see Heidegger, 1991[1947]) was a major influence on a generation of French writers such as Michel Foucault (1970 [1966]) and Jacques Derrida (1982b), collectively identified under the sign of poststructuralism, whose reformulations proved influential in the Anglophone academy. The white, heterosexual adult who is generally a cipher for the 'human' of classical humanism has also been criticized from a range of perspectives. Not all of these take the strong anti-humanist perspective that denies agency and responsibility, which is often seen as politically disabling, but the challenge to the universalizing tendencies of classical humanist reasoning has been pervasive. In human geography, this critique has led to a broadly understood posthumanist tradition.

apartheid A political and legal system of racial classification, spatial separation and discrimination against black South Africans. Associated with the white minority National Party that came to power in 1948, apartheid policies built on pre-existing forms of racial segregation and dispossession, but took them in new directions.

Dismissing presumptions of South African exceptionalism, Mamdani (1996) maintains that apartheid was simply a variant of indirect rule through which colonial power operated in other parts of Africa (see colonialism). While acknowledging these continuities, Alexander (2002, p. 140) insists that 'the fact of a large population of European descent [...] does make all the difference'. So, too, do the interconnections between institutionalized racism and forms of class exploitation that characterized apartheid.

Apartheid officially died in 1994, when the African National Congress (ANC) received overwhelming support in South Africa's first non-racial election, which marked the transition to liberal democracy. Yet apartheid retains a powerful afterlife in terms of persistent racial, spatial and economic inequalities in South Africa, and as emblematic of ongoing forms of racialized oppression around the world.

Gross violations of human rights committed during the apartheid era were the focus of the Truth and Reconciliation Commission (TRC), which has become a model for countries all over the world seeking to come to terms with histories of violence. Between 1996 and 1998, the TRC received 20,000 statements from victims and nearly 8,000 applications for amnesty from perpetrators. In her compelling account of the TRC, Krog (2000) illuminates its accomplishments, limitations and ambiguities, along with chilling testimonies of many who bore the brunt of state-sanctioned violence. The final report of the TRC, submitted in 2003, recommended that the government pay some US $375 million in reparations, and that businesses that had benefited from apartheid policies make reparations through a special wealth tax. President Thabo Mbeki authorized a one-time payment of R30,000 (approximately US $5,000) to each of about 22,000 people defined as victims of apartheid, but refused to impose a tax on businesses.

The debate over apartheid reparations overlaps with the ANC government's controversial embrace of a conservative package of neoliberal macro-economic policies in 1996 (Bond, 2000; see neo-liberalism). The post-apartheid era has seen the rapid emergence of an African middle class and a small but extremely wealthy corporate black elite. Yet huge numbers of black South Africans remain in impoverished conditions in poorly serviced and densely populated townships, rural reserves and slum settlements. Persistent poverty and inequality have prompted some critics to argue that there has been a shift from race to class apartheid, while others contest this formulation. Since 2001 many oppositional movements have arisen demanding access to resources, and fierce protests have erupted in many different parts of the country. Despite these challenges, the ANC continues to exercise considerable hegemonic power – a testimony, perhaps, to the ongoing importance of nationalism, grounded partly in histories and memories of the struggle against apartheid.

Global apartheid, some maintain, is a more adequate description of the current world order than apparently race-neutral terms such as globalization or neo-liberalism, and can also bolster efforts to transform global
minority rule. Experience in post-apartheid South Africa has much to contribute to struggles aimed at deepening democracy and challenging inequality.

applied geography This is a notion that necessarily operates at a number of different levels. On the one hand, geographical research and the production of geographical knowledge are activities that necessarily relate to the ‘real world’. Geographers are attempting to understand the physical and human world, and their knowledge is produced in a dialectic with the world around them. In addition, their knowledge is disseminated to others – and particularly students – in a way that is likely to shape people’s beliefs and behaviour. In this regard, all knowledge is potentially applied.

On the other hand, however, there are particular strands of geographical enquiry that prioritize the production of knowledge that can be applied to solving pressing issues or concerns in society. There are strong strands of geographical research in the fields of environmental policy, development and urban and regional planning that have been more applied. It is also important to note that any field of human geography and physical geography can potentially be applied to the development of policy. Geographers might be contracted to do research about a social concern and highlight the potential policy implications of their findings. They may also be consulted as experts in order to draw on their knowledge in the production of public policy. Yet further, geographers might highlight their own views about potential policy-making by the state, corporations or civil society as a result of their own research or insights. There is clearly a place for geography to be applied through policy engagements of various kinds and there have long been vocal calls to do more of this work – for the debate in the 1970s, see Coppock (1974) and, more recently, see Martin (2001b) and Ward (2005a).

It is useful to distinguish this focus on policy from a wider set of engagements and applications that we can call public geographies. Echoing recent debates in the discipline of sociology (see Burawoy, 2005), a number of geographers are beginning to rethink the way in which academics engage with, and even create, audiences through their research, teaching and in their roles and performances as intellectuals in the wider society (Murphy, 2006; Ward, 2006). In this model, the discipline itself comprises different interlocutors such as students and fellow academics with whom there is an ongoing dialogue over the production and dissemination of ideas. In addition, there are multiple publics with whom academics might engage with as part of their own work, exploring new developments, testing out ideas and putting research into action. The explosion of interest in action research and participant observation methodologies that seek to empower research groups and participants is in part a reflection of this shift towards public collaborative engagement through our research (see Hale and Wills, 2005). Furthermore, the practice of research can itself constitute audiences, however fleetingly, through activities such as holding a workshop or conference to disseminate findings, publishing research material and papers on the Internet, or taking part in media coverage of events.

Geography and geographers can add significantly to understanding the contemporary human and physical world at a time when issues of geography are increasingly pressing. There is clearly a place for applying such knowledge on a whole range of fronts, from the most powerful intellectual interventions about contemporary neo-liberalism and war (Gregory, 2004b; RETORT, 2005), to ongoing engagement in the problems of civil society and the development of policy for particular ‘clients’. Our notion of applied geography thus needs to be widened far beyond the traditional focus on policy, to incorporate the discipline’s relevance to multiple audiences and political forces for change.

area studies Academic programmes that cut across disciplinary boundaries to develop a relatively comprehensive body of knowledge about given regions – or areas – of the world. There is a history of such regionally based, interdisciplinary studies that pre-dates the Second World War (Said, 2003 [1978]), including within geography. Contemporary area studies, however, and the world regions that they have taken as objects of study, are largely a post-Second World War phenomenon.

At the end of the Second World War, the US government took on a leading role in funding area studies programmes within US universities in order to develop the academic expertise
necessary for effective management of the national project of world leadership (Gendzier, 1985). In the COLD WAR era, some of the first areas of major concern were in EUROPE, but area studies programmes were also quickly developed for regions of ASIA (including the MIDDLE EAST) and the rest of the so-called THIRD WORLD (Cumings, 1998). Although the intention of the US government in funding such programmes clearly had to do with the need to develop knowledge useful to the maintenance of imperial power (see AMERICAN EMPIRE), the kinds of work done within area studies came to vary widely, both methodologically and politically (Wallerstein, Juma, Keller et al., 1996).

Methodologically, area studies programmes brought together scholars from a range of social sciences – including anthropology, applied economics, geography, history, political science and sociology – as well as various HUMANITIES and physical sciences disciplines. This spurred a significant amount of interdisciplinary collaboration and is credited by some scholars with having helped erode disciplinary boundaries in the post-Second World War academy (Wallerstein, Juma, Keller et al., 1996, pp. 36–48).

While many early Cold War studies were animated by a desire to serve the US government’s overseas projects – even leading in some cases to considerable controversy within disciplines over the appropriate role of scholarship – many area studies programmes also came to serve as the home base for a range of critical scholarly endeavours that questioned these same US policies (Anderson, 1998, pp. 11–12). This was the case, for example, in Asian studies, where a group called the ‘Concerned Asian Scholars’ came together during the Vietnam War, challenging the views of Asianist scholars who supported the US war effort. Likewise, scholarship critical of US foreign policy agendas has frequently emanated from fields such as Latin American and Middle Eastern studies.

Suggested reading

areal differentiation The study of the spatial distribution of physical and human phenomena as they relate to one another in REGIONS or other spatial units. Also sometimes referred to as CHOROLOGY, it is, with LANDSCAPE and SPATIAL ANALYSIS approaches, often regarded as one of the three main conceptions of HUMAN GEOGRAPHY. Of the three, it is the oldest Western tradition of geographical enquiry, tracing its beginnings to the Greeks Hecateus of Miletus and Strabo, although the term itself only dates from the 1930s. In Strabo’s words, the geographer is ‘the person who describes the parts of the Earth’. Description, however, has never been just taking inventory of the features of regions. The purpose was always to relate the features to one another to understand how PLACES differ from one another and how this has come about. As the theoretical justification for studying REGIONS and REGIONAL GEOGRAPHY, use of areal differentiation has waxed and waned down the years, with different proponents using distinctive concepts and language.

The ‘classic’ epoch of regional geography, to use Paul Claval’s (1993, p. 15) turn of phrase, was reached in the late nineteenth and early twentieth centuries, when much of the theoretical debate in geography was devoted to the concept of the region. The most important modern statement of geography as areal differentiation was made in Richard Hartshorne’s The nature of geography (1939). Though often viewed as an argument for the uniqueness of regions, the logic of the presentation suggests that recognizing regions requires investigating similarities as well as differences over space. In the 1950s and 1960s, critics of regional geography succeeded in marginalizing the focus on areal differentiation as they pushed a redefinition of the field in terms of spatial analysis. In the 1980s, however, the approach made something of a comeback. But the revival is neither directly connected to older debates such as that between Hartshorne and his critics, nor is it monolithic. Three positions can be distinguished. One involves a focus on place-making as an essential human activity. A second sees regional differences in terms of processes of UNEVEN DEVELOPMENT that are forever rearticulating the global DIVISION OF LABOUR under CAPITALISM. A third attempts reconciliation between the first two by seeing places or regions as settings for the interpellation of HUMAN AGENCY and the conditioning effects on it of social and environmental context.

Persisting dilemmas limit the possibility of unifying these positions. For one thing, the question of whether regions are ‘real’ or exist solely in the mind of the observer continues to wrack debate (Agnew, 1999). There are also important differences over narrative versus analytic modes of thinking and presentation, the relevance of regional divisions in an
increasingly ‘networked’ world, and the best terminology (such as that of place versus region).

art Geography has a long-standing and multifarious relationship with art. GEOGRAPHY’S literal meaning as ‘earth writing’ and its concern with visual REPRESENTATION have often brought the discipline into close involvement with artistic practices, with geographical knowledge frequently being dependent upon skills of visual survey and graphic recording such as sketching, drafting and painting, especially during the period of European EXPLORATION (Cosgrove, 1999). The significance of an aesthetic sensibility continued through much CULTURAL GEOGRAPHY and REGIONAL GEOGRAPHY in the early twentieth century; for example, in Carl Ortwin Sauer’s studies of CULTURAL LANDSCAPES and in the pictorial language with which Paul Vidal de la Blache referred to landscape description. Geographical interest in visual art has taken many forms. These include studies of representations of spaces, places and environments in a range of artistic media, especially in terms of the politics of representation, ideology, identity and the construction of IMAGINATIVE GEOGRAPHIES. Also important is geographical research on art production (e.g. the formation of local, regional and national artistic traditions; the role of arts industries in economic and urban change; the spaces of artistic creativity); on art dissemination and reception (including through artistic networks, institutions, audiences, and public engagement with and contestation of works of art); and on art practices (as embodied creative processes, as expressions and forms of geographical knowledge, as interventions in and performances of spaces and places).

Geography’s reconstitution as a SPATIAL SCIENCE in the 1950s and 1960s sidelined such artistic considerations, although a concern with visualization and the aesthetics of order can be discerned in geometric spatial modelling (Gregory, 1994). HUMANISTIC GEOGRAPHY brought an interest in the expressive and emotional engagement of art with places through its emphasis on subjectivity and human experience. The emergence of a politicized cultural geography in the 1980s, influenced by MARXISM as well as social histories of art and broader currents of cultural theory, turned critical attention to the social conditions and power relations through which art is produced as part of a concern with the politics of representation. Significant studies focused on the constitution of the Western idea of landscape as a ‘way of seeing’, and on its role in naturalizing class and property relations, in articulating visions of national identity, and in legitimating colonial interests (e.g. Daniels, 1993; Cosgrove, 1998 [1984]). Feminist critics also emphasized the importance of gender relations and SEXUALITY in discussions of visuality and landscape (see also VISION AND VISUALITY).

Recent geographical interest in art has become more extensive and diverse. While much work remains focused on visual and ICONOGRAPHIC readings of artefacts such as paintings, drawings, MAPS, photographs, landscapes, architecture, MONUMENTS and sculptures, research has also addressed the spatialities of sound art, land art, street art, MUSIC, video, FILM, performance and dance, among other fields. Attention has turned in particular to artistic practices and to the embodied, processual and performative elements of art (see PERFORMANCE). Studies have thus drawn out the bodily practices and sensory immersion in places involved in visual art production (Crouch and Toogood, 1999), and to a lesser extent viewing and reception. They have also explored the ways in which modern and contemporary artistic practices have directly engaged with urban and rural geographies, from attempts by twentieth-century avant-gardes such as the dadaists, surrealists and SITUATIONISTS to break down divisions between art and everyday spaces, to more recent ‘works’ and interventions by performance artists, conceptual artists, community artists and others. The latter often take collectivist, collaborative, ethnographic or dialogical approaches, based not on the individualized production of aesthetic objects but on practices such as URBAN EXPLORATIONS, walks, participatory events, investigations of social spaces and sites, and interactions with groups and communities. They are also frequently politicized or activist, forging public arenas for political discussion and critical engagement with the processes through which spaces are produced (Deutsche, 1996b; for examples, see Cant and Morris, 2006; and the ‘Cultural geographies in practice’ section of the journal Cultural Geographies). Alongside researching such art, a number of geographers are collaborating with artists (e.g. Driver, Nash, Prendergast and Swenson, 2002). Some are further experimenting themselves with artistic and performative practices.
as a critical and imaginative means of addressing geographical concerns.

**artificial intelligence**  
Computerized decision-making that simulates human expert decision-making. In its simplest form, artificial intelligence (AI) consists of a body of procedural rules (e.g. the linear IF THEN ELSE rules that are the mainstay of computer programming). Or it can describe a heuristic type of intelligence that surpasses simple procedural instructions. Artificial intelligence can relieve humans of tedious tasks such as addition of grocery prices. For such simple tasks, it often surpasses humans in speed and accuracy but can fall short when asked to codify knowledge in a holistic manner. Since the early 1990s, more sophisticated AI has sought to emulate human thinking using parallel computing (e.g. neural nets and genetic algorithms). These techniques have been more successful than traditional linear rule-based systems in classifying area types or identifying regional zones. They have also been used for map generalization - a task that requires processing of multiple decision-making facets including context, intention, scale and contiguity. In each case, neural nets and genetic algorithms teach themselves based on positive or negative reinforcement during 'training'. In the case of neural nets, a series of images corresponding to a given classification may be 'fed' into the net. Subsequent training rewards the net for choosing the right classification. At the present, AI is only able to emulate very simple human decision-making though the promise of truly intelligent computing.

**Asia (idea of)**  
Considered the world’s largest continent but actually part of a single landmass with Europe (the conventional dividing line being the Ural and Caucasus mountains), Asia lays claims to being the 'cradle of human civilization' as it is home to important ancient civilizations - including those of China, India, Japan and Persia - that generated major developments in agriculture, urbanism, religion and other fields of human expression (Parker, 1994, p. 4).

Derived from Greek and first used to describe the region later known as Asia Minor, ‘Asia’, like other related terms such as the ‘Orient’ or the ‘Far East’, is a cartographic construct imposed from the outside rather than a pre-existing geographical reality. Depicted on eurocentric maps of the world as the ‘east’, European colonizers tended to frame Asia in oppositional terms to Europe: as culturally degenerate, environmentally debilitating and inherently backward, in contrast to Europe’s civilizational progress and enlightenment (Weightman, 2006). As a conceptual category, the term ‘Asia’ has continued to evolve, often in response to external categorization. The term for the sub-region of South East Asia, for example, has only gained currency since the Second World War, when the region gained visibility in military and strategic terms under the South East Asia Command established in 1943, and consequently achieved legitimacy in international eyes (Savage, Kong and Yeoh, 1993). ‘Asia’ as a construct is also subject to internal pressures. For example, the term ‘Asiatic’ to refer to the inhabitants of Asia or as an adjective pertaining to Asia has now been superseded in common usage by ‘Asian’: the former nomenclature fell out of favour in the postwar era, as it had become laden with pejorative implications during European colonialism.

Today, Asia’s 3.6 billion people account for about three-fifths of the world’s population. China, the most populous nation in the world, has a current population of more than 1.2 billion people, followed closely by India, with a population of slightly over a billion (United Nations, 2005). Although the world’s population growth rate is now generally declining, and in Asia it is likely to fall even further below the global rate, nonetheless, the developing countries of Asia will still be major contributors to world population growth for many decades to come. More than a third of Asia’s population live in urban areas, including some of the largest megacities in the world.

Considering Asia as one geographical entity, however, belies the diversity in cultures and peoples, as well as a wide range of economic, political and demographic structures. Migration, trade, war and European colonization in the past had contributed to contact, exchange and syncretism in many spheres of life within the region. Despite the new sense of Asian solidarity expressed during the Bandung Conference of 1955 to sever ties of dependency on the West, different approaches to decolonization and nationalism in the mid-twentieth century led the countries in Asia down divergent pathways (Parker, 1994, p. 10). The more
The recent pursuit of modernity and global futures has also been characterized by uneven and different trajectories for countries in Asia. Optimism about the region based on the runaway success of some East and South East Asian 'miracle' economies (see ASIAN MIRACLE/TIGERS) was suddenly brought up short as the region floundered in crisis in the closing years of the twentieth century (Chapman and Baker, 1992; Forbes, 2005).

**Suggested reading**

**Asian miracle/tigers** A popular description of East and South East Asian countries that had exceptionally high rates of economic growth from the 1960s until the Asian economic crisis of 1997. Some lists of the Asian miracle economies include Japan, but most early discussions focused on Hong Kong, Singapore, South Korea and Taiwan, also called the 'first tier' Asian newly industrializing countries (NICs). After the economic boom extended to Southeast Asia in the 1980s and 1990s, authors began to speak of Indonesia, Malaysia and Thailand as part of the miracle, and some discussions of China's rapid growth since the 1990s also place it on the list of tigers/miracle economies.

The World Bank's *East Asian Miracle* report (1993) put an official seal on the language of miracles, though the bank's analysis argued that the rapid growth of these economies was not in fact miraculous and could be replicated by other countries. The report was met with varied forms of criticism, however, and there have been analysts who question whether the performance of the Asian NICs is replicable or should be celebrated as uncritically as it often has been.

The *East Asian Miracle* report generally credited neo-liberal policies with responsibility for the boom, including maintenance of export-oriented trade regimes, though it acknowledged some benefits from policies of 'financial repression', such as state-imposed below-market interest rates for loans to specific exporting industries. Various institutionalist analysts criticized the bank for overlooking a range of other state policies that facilitated growth, but that do not fit the tenets of NEO-LIBERALISM (Wade, 1996).

Other analysts have criticized celebration of the Asian NICs performance, regardless of the specific role of states in their growth. Criticisms have included concerns about the political repressiveness of Asian states and environmental destruction caused by rapid growth. After the economic crisis hit many of the tigers in 1997, some analysts also began to question the economic sustainability of the Asian NIC growth model (Hart-Landsberg and Burkett, 1998). In addition, some authors have noted that the Asian miracle has much to do with the development of a networked, COLD WAR era, regional production hierarchy, led by Japan, which is both geographically and historically specific — and thus not readily replicated even if it does present a desirable model (Cumings, 1984; Bernard and Ravenhill, 1995).

**Suggested reading**

**assemblage** The process by which a collective asian miracle/tigers entry entity (thing or meaning) is created from the connection of a range of heterogeneous components. A translation of the French word *agencement*, the solidarity of the English term tends to make it sound more static, rational and calculated than the original term signifies. In fact, it is precisely the sense of an aggregate with a certain consistency being created from an active, *ad hoc* and ongoing entanglement of elements that has made the notion so attractive to authors working in a post-structuralist vein. The concept has been put to work notably in science and technology studies (STS) (see Law, 2004), the work of Jacques Derrida, and – most significantly – the combined writings of Gilles Deleuze and Félix Guattari (1998).

**assimilation** A particular form of the social integration of people into a new society, typically after they have migrated from another country (cf. migration). There are many forms of integration, which include social exclusion (denying migrants basic social rights), assimilation, *laissez-faire* approaches (leaving migrants alone to choose their own mode of social engagement with mainstream society) and pluralism (allowing migrants to retain their cultural traditions and live separately from mainstream society). Assimilation is a process whereby migrants give up their cultural traditions, including attire, language, cuisines and ways of thinking, and take on the cultural traditions of the society in their destination country (Gordon, 1964; Glazer and Moynihan, 1970). The classic immigration-based countries — the USA, Canada,
Australia and New Zealand – all expected migrants to assimilate for most of their history. Recently, Canada and Australia have adopted the policy of MULTICULTURALISM as a new mode of migrant integration, which is a kind of hybrid between assimilation and pluralism (Hiebert and Ley, 2003). Several European countries also adopted multicultural policies in the latter decades of the twentieth century, notably the Netherlands, Sweden and the UK. Other European countries, such as France and Germany, have been wary of multiculturalism and continue to expect migrants to assimilate. In the aftermath of terrorist incidents and several episodes of social unrest, those European countries that adopted multiculturalism appear to be reconsidering that decision, and may be returning to assimilation as a means of integration (Vasta, 2005). These debates have been highly politically charged, and critics of the return to assimilation have argued that it reflects an Islamophobic agenda. DH

Asylum Asylum has two distinct meanings in HUMAN GEOGRAPHY. One stream of work has been directed towards the (historical) geography of institutions for mental illness (Philo, 2004; and see MEDICAL GEOGRAPHY). Another body of work examines asylum as the displacement of refugees from one state to another, in which they seek sanctuary from violence and political persecution (Hyndman, 2000). The two are very different, but both of them raise searching questions about marginalization and the production and location of ‘outsiders’. JH

Austral(as)ia, idea of The term ‘Australasia’ is a construct of IMPERIALISM. As a means of delineating and denoting a diversity of far-flung colonial territories, it had wide currency in the nineteenth century, both in the metropole and regionally. If it retains some utility in the former context, it is ‘a repressed memory’ in the latter (Denoon, 2003). This is despite continually evolving regional memory in the former context, it is ‘a repressed memory’ in the latter (Denoon, 2003). This is Despite continually evolving regional memory, it is ‘a repressed memory’ in the latter (Denoon, 2003). This is because of the particularities of relations with indigenous peoples in the different territories.

In the 1920s ‘Australia Unlimited’ was promoted by boosters who envisaged population capacities of 100–500 million and saw a dominant Australia as ‘the future pivot of white settlement in a secure and revivified empire’ (Powell, 1988, p. 131). The geographer Griffith Taylor, whose prediction of a population of only 20 million in 2000 was prescient, challenged this vision cartographically, labeling much of the Australian interior as ‘uninhabited’ and ‘almost useless’. This echoed another colonial imaginary, that of Australia as TERRA NULLIUS, or no one’s land, prior to European settlement. Not until the Mabo judgement of 1992 was native (or aboriginal) title recognized in Australian common law (Whatmore, 2002c) (cf. ABORIGINALITY).

Mabo has ‘unsettled’ Australia, bringing to the fore contestations over national aspirations that also characterize the other countries of what was ‘Australasia’. The past has also
returned to haunt the present in another guise: whereas Australasia was originally used to mark a separation from Asia, in recent years regional geographical imaginaries have been both dislocated and reoriented by deepening economic and cultural connections between the two.

**authenticity** The genuineness, trustworthiness and accuracy of an object or an account. Human geographers have addressed the issue of authenticity in relation to a whole raft of questions from identity politics (e.g. the gendered self) to our understanding of and relationship with nature. In all cases there has been a shift away from an essentialist concept of the authentic (cf. essentialism) to a more partial, constructed and situated notion of what passes as authentic (Whatmore, 2002a). Rather than presenting a foundationalist account of authenticity, human geographers are tracing how particular versions of authenticity get played out in the knowledge-making practices of specific times and places (Livingstone, 2003c).

Livingstone (2003c).

**azimuth** The azimuth is the horizontal (‘on the ground’) angle between a given direction and some line of reference (a meridian). Imagine that you stand looking northwards along the Grand Meridian (zero degrees longitude) at Greenwich, England – the official starting point for each new day. A bird flies nearby and you turn your feet towards its shadow on the ground. The angle you have rotated defines the azimuth. Because that angle usually is measured with a compass, azimuth is synonymous with bearing. But be warned if travelling to the North Pole – the azimuth you should follow is not magnetic north! 

Suggested reading
back-to-the-city movement  A term usually indicating repopulation of cities by former suburban residents. The perception of a back-to-the-city movement has, since the 1990s, been influenced by media reports and some research studies that indicate, advocate, and/or celebrate the return of mostly affluent class fractions to some inner-city neighbourhoods (Florida, 2002). The term is, then, closely associated with discussions of gentrification. Recent research in the USA cautions that most residential migration still involves suburbanization or counter-urbanization and notes that we are far from seeing a widespread back-to-the-city movement (Kasarda, Appold, Sweeney and Sieff, 1997).

balkanization  The fragmentation of a larger political entity into smaller, mutually hostile units. The term originates from the geopolitics of national self-determination in a context of continental power rivalries in the Balkans at the end of the nineteenth century. The term returned to prominence with the break-up of Yugoslavia in the 1990s, and was brought to bear upon other states, especially Russia. Balkanization has been used as a metaphor for immigration patterns into the USA producing a spatial and social segmentation of the population (Frey, 1996: see segregation). Such usage has been contested for its negative connotations (Ellis and Wright, 1998). CT

bare life (‘naked life’)  Life that is excluded from political participation, and so can be abandoned to violence and death without recrimination or penalty. The emphasis on exclusion and abandonment is vital: ‘bare life’ is not a given but is socially produced. Agamben (1998) claims that classical Greek philosophy made a vital distinction between political life (bios) and merely existent, biological life (zoe): and, as he uses the term, bare life is actively poised between the two. To show how vulnerable such a position is, Agamben locates the production of bare life at the intersection of two distinctive modalities of power: sovereign power and biopower.

His thesis is a double critique of Michel Foucault’s theses on biopolitics, disciplinary power and governmentality.

(1) Agamben refuses Foucault’s historical trajectory. Foucault (1981/1976, p. 141) argued that a crucial junction between modernity and capitalism was the novel ‘entry of life into history’ that took place in eighteenth-century Europe, whereas Agamben insists that ‘the inclusion of bare life in the political realm constitutes the original – if concealed – nucleus of sovereign power’: in other words, for Agamben this is a process with a much longer history (which is why he returns to classical philosophy). What characterizes political modernity for Agamben is then the ‘coincidence’ of bare life with the political realm, but a coincidence that is profoundly contradictory: bare life is no longer at the margins of the political order, in fact it becomes a central object of political calculation, but it is also excluded from its deliberations (Mills, 2004, p. 46). It is by no means clear that Foucault and Agamben mean the same thing by ‘life’, but the bearers of Agamben’s ‘bare life’ are political objects not political subjects: they are wilfully exposed to violence and death because they are treated as though they do not matter so that, collectively, they become so many versions of homo sacer.

(2) Agamben twists Foucault’s spatial template. His account turns not on strategies through which the normal order contains and confines its ‘outside’ – the sick, the mad, the criminal, the deviant – but on strategies through which the ‘outside’ is included ‘by the suspension of the juridical order’s validity – by letting the juridical order withdraw from the exception and abandon it’. Agamben argues that this space of exception (see exception, space of) is typically produced through martial law and a state of emergency, which then become the ground through which sovereign power constitutes and extends itself.
Agamben treats the camp as the exemplary locus of the production of bare life. He does not confine the camp to particular locations, but other writers have seen the production of bare life in the plight of refugees in Kosovo (Edkins, 2003), in the contemporary ‘war on terror’ in Afghanistan, Palestine and Iraq and its global war prison (Gregory, 2004b, 2006b), in post-colonial violence in Rwanda and Zimbabwe (Sylvester, 2006), and in post-Katrina New Orleans (Braun and McCarthy, 2005). The disposition to abandon people in this way, visible in early and late capitalism, has economic and well as political coordinates, and these imperatives have been vigorously reasserted under the sign of neo-liberalism (cf. Bauman, 2004).

Suggested reading

**barrio** A Spanish word meaning ‘neighbourhood’. The term’s various significations in the Americas are rooted in Spanish colonialism. Colonial cities were laid out in a grid pattern radiating out from a central plaza, church and government buildings (Bakewell, 2004). Residence near the plaza was reserved for the city’s principal vecinos, or citizens. Poorer residents, with varying citizenship status, lived in barrios on the outskirts of the town. Thus, urban location signified social, political, economic and racial status. In Latin America today, ‘barrio’ may signify a neighbourhood or a squatter settlement (see squatting); the actual cultural signification assigned to the term varies widely (Clawson, 1997, p. 319).

In the Mexican states annexed by the USA in 1848 after the Mexican–American War, the term referred to the neighbourhoods inhabited by Mexican-Americans. Raúl Homero Villa (2000, pp. 4, 7) proposes the terms barrioization to refer to the external legal and ideological structures that contribute to the formation of segregated barrios and barriology to describe the internal processes of place-making that facilitate the creation of Mexican-American communities. For Mexican-Americans, ‘barrio’ is associated with both the poverty resulting from dispossession and the ‘feeling of being at home’ (Griswold del Castillo, 1979, p. 150).

Villa (2000).

**base and superstructure** The metaphor that Marx uses to express the idea that the economic structure of society (its ‘base’) conditions corresponding legal and political superstructures and forms of consciousness. As Marx succinctly puts it in the Preface to his 1859 work *A contribution to the critique of political economy*, ‘The mode of production of material life conditions the social, political and intellectual life process in general’ (see marxism; mode of production).

The relationship is more complicated than it appears. Marx and Engels subsequently denied that this formulation implied a simple economic determinism, and insisted that there were many forms of reciprocal effect between base and superstructure. This did not prevent the hardening of the distinction in the often mechanical interpretations that were systematized in textbooks by Marx’s immediate followers (such as Plekhanov). The tendency amongst Marxists in the more recent past has been to downplay the metaphor as too crude to capture the complexity of interrelationships that Marx was trying to encapsulate (interactions between base and superstructure are more evident in some of his historical analyses, such as ‘The Eighteenth Brumaire of Louis Napoleon’). It has also proved difficult to maintain a simple base/superstructure distinction when many superstructural elements – such as legal conceptions and scientific knowledges – clearly enter into the economic base.

Cohen (1978) has provided a sophisticated, modern restatement in functionalist terms that tries to clarify these issues (see functionalism). On his reading, the economic base comprises relations of production (but not forces of production), and the superstructure is much smaller than is often supposed, comprising only those non-economic institutions, such as legal systems and the state, that are functionally necessary to the reproduction of the economic base (art, for example, is thus largely excluded).

Althusser (see Althusser and Balibar, 1970) tried to resolve the problem in a different way by developing a further distinction that Marx made between ‘determination’ and ‘domination’ in his claim that politics played the dominant role in the ancient world and religion in the Middle Ages. Althusser interprets this to mean that the economic structure is only ‘determinant in the last instance’, and may not itself play the dominant role in many social formations, although it determines which of the other levels assumes that dominant role. For Althusser, therefore, the social system is thus a complex totality ‘structured in dominance’. Following Althusser, ‘anti-essentialist’ Marxists such as Resnick and...
Wolff (1987) and Gibson-Graham (2006b [1996]) have gone further in dissolving the very notion of the economy as a separate space with deterministic effects, replacing base and superstructure with the notion of a centred, over-determined totality with no essential, determining structure (cf. ESSENTIALISM).

Harvey (1999 [1982]), on the other hand, continues to emphasize the classical role of the economy and the dynamics of capital ACCUMULATION in shaping social (and, crucially, CLASS) structures under capitalism, but avoids simple base/superstructure distinctions by conceptualizing economic and superstructural elements as ‘moments’ in the total circulation process of capital.

In summary, although the base/superstructure distinction is too crude to provide an answer, it does point towards the key question of the nature of ‘the ECONOMY’ in capitalist systems and its influence on, and interaction with, wider social, cultural and political structures. KB

Bayesian analysis A type of statistical modelling and estimation deriving from the early ideas of the Reverend Thomas Bayes, who developed his ‘doctrine of chances’ in 1763 (Bayes, 1763 [1958]). The Bayesian perspective differs from traditional or ‘orthodox’ statistical inference in giving explicit recognition to the role of prior ideas and probabilities and so is sometimes labelled as a ‘subjective’ approach to probability and statistics. Much of the probability theory was developed by 1939, when Jeffreys wrote his classic text (Jeffreys, 1998 [1939]), but the implementation of Bayesian methods as a practical statistical technique is much more recent, and had to await modern computer technology and the invention of some very clever new devices.

Bayes’ central idea is that prior probabilities are updated by confrontation with data to provide posterior probabilities. For example, suppose we want to make inferences about a parameter \( \theta \) (which might be a mean or a REGRESSION coefficient). Our prior probability distribution for \( \theta \) is \( p(\theta) \). The observed data are represented by the likelihood function \( p(y|\theta) \). Using Bayes’ rule on conditional probabilities gives us the posterior density or distribution \( p(\theta|y) \) as follows:

\[
p(\theta|y) = \frac{p(\theta)p(y|\theta)}{p(y)},
\]

where \( p(y) = \sum_{\theta} p(\theta)p(y|\theta) \), the sum over all possible values of \( \theta \), which acts as a normalizing constant. This term may be ignored in many instances (though not in MODEL comparison) to give the unnormalized posterior density:

\[
p(\theta|y) \propto p(\theta)p(y|\theta).
\]

This expression defines the core of Bayesian inference. Note that this method derives a posterior probability distribution for \( \theta \), whereas classical (or standard) inference uses the sample data to make inferences about the unknown, but assumed fixed, parameter value of \( \theta \). Where there are several parameters in question, such as \( \theta_1 \) and \( \theta_2 \), then \( p(\theta|y) \) is a joint distribution, and the Bayesian statistician converts this to two marginal posterior distributions by integrating across the range of the other \( \theta \):

\[
p(\theta_1|y) = \int p(\theta)p(y|\theta)d\theta_2.
\]

In this framework, inferences about \( \theta_1 \) are made taking account of the full distribution of \( \theta_2 \), whereas classical inference is based just on the optimal point estimates and local curvature around that location.

Opinions about the potential of Bayesian methods have differed sharply. Some have seen them as a way of broadening the scope of quantitative analysis, whilst others have rejected the notion of bringing SUBJECTIVITY into statistical inference. In practice, Bayesian methods were little used except for circumstances under which they were equivalent to classical results and so there was no computational difference, only one of interpretation. More direct implementation depended on the facility to do the numerical integrations required to get the marginal distributions, and modern computing provided this. In the social sciences, the work of the Chicago econometrician Arnold Zellner was very important in this process (Zellner, 1971).

Modern Bayesian analysis is usually based on ‘uninformative’ or ‘diffuse’ prior information, reflecting prior ignorance or a determination not to introduce subjective prior information into the analysis; Bayesian estimation is then used very much as a technical device to estimate posterior distributions.

Bayesian methods have taken a further leap forward in the past decade with the construction of Markov Chain Monte Carlo, or ‘MCMC’, techniques (Gilks, Richardson and Spiegelhalter, 1996). It has been shown that
complete sets of joint and marginal posterior distributions may be constructed by this simulation method. Starting from the (diffuse) prior distributions, the conditional distributions of the $\theta$-parameters are sampled using random sampling (hence the ‘Monte Carlo’ part of the name) and these sampled $\theta$ values are then brought together with the data to estimate the likelihood. This information is then used to update the conditional distributions, and the process is repeated many hundreds or thousands of times, gradually building up samples representing the posterior distribution. The sampling at any stage $t$ is based on updating from the conditionals at time $t-1$, and hence it is a (first-order) Markov chain process. This remarkable method can be developed for very complicated models with many parameters and difficult structures, and is being used in many disciplines. Models in both spatial econometrics and multi-level modelling may now be estimated by these Bayesian methods.

Bayesian methods have been applied in several areas of geographical and spatial analysis. The specific version of ‘empirical Bayes’ estimation is widely used in spatial interpolation and in disease mapping and spatial epidemiology. Other applications include population and economic forecasting, crime ‘hotspot’ modelling, and hierarchical Bayes estimation to lend insight into the problem of ecological inference. Brunsdon (2001) provides a case-study using MCMC in a Bayesian model predicting school performance figures for pupil-tests. In spatial econometrics, Bayesian methods, both numerical integration and MCMC, have been used to estimate models with spatial endogeneity and more complicated forms (Hepple, 1995; LeSage, 1997). The geographer Peter Congdon has written two major statistical texts on Bayesian statistical modelling (Congdon, 2001). Opinions still differ about the role of subjective prior information, but modern Bayesian methods are one of the fastest developing areas of quantitative analysis.

behavioural geography A sub-discipline emphasizing the psychological underpinnings of individual spatial behaviour; in particular, the cognitive and decision-making processes that intervene between a complex environment and human action. In its earliest expression this work was more humanistic, exemplified in the historical musings of J.K. Wright in the 1940s (Keighren, 2005), and the influential essays of Lowenthal (1961) and Brookfield (1969) on environmental experience and perception. While this tradition led into humanistic geography, behavioural geography was typically more formal and analytic, drawn into the positivist paradigm of locational analysis. Its characteristic question was: Given the assumption of rational behaviour, why did an actual location or pattern of spatial behaviour depart from an optimal form? (See location theory.) The answer was seen to be a product of decision-making, and notably the human tendency to have only incomplete information, to make imperfect choices, and to be satisfied with sub-optimal options. Applications included Wolpert’s (1964) study of Swedish farmers and Pred’s (1967) analysis of industrial location. In each instance, behaviour was seen to be satisficing rather than optimizing as predicted, for decision-makers were not only incapable but even unwilling to compromise other values in order to maximize their utility functions. Similar work examined the journey to shop, and showed again how, both in terms of retail location and shopping behaviour, cognitive variables intervened to complicate geographically rational behaviour (see retailing). A particular emphasis was upon preference structures in spatial behaviour, modelling such topics as place utility and residential search. The most celebrated work was conducted by Peter Gould and his students who examined the mental maps, or preference surfaces, within different countries held, usually by students, and which might permit the prediction of subsequent migration (Gould and White, 1993 [1974]).

One of the most interesting and applied aspects of behavioural geography was work examining human perception of environmental hazards. Typically, this research addressed itself to a seemingly anachronistic location decision. Why did people or industry locate in unpredictable sites such as floodplains or areas of earthquake or avalanche hazard? How was such irrational behaviour to be explained? The pioneering work by Robert Kates and Gilbert White on floodplain hazards inspired many subsequent studies, which included increasing methodological sophistication. For example, Saarinen’s (1966) innovative study of the perception of drought hazard by farmers on the Great Plains postulated the existence of a distinctive personality disposition, which he explored using the thematic apperception test, a personality...
assessments. A range of related personality assessments, such as personal construct theory and the semantic differential, were employed, and in this work geography and psychology became close neighbours (Aitken, 1991; Kitchin, Blades and Golledge, 1997). During the 1970s, in particular, this productive interdisciplinary relationship was developed through the annual meetings of the Environmental Design Research Association and in the pages of the new journal, Environment and Behavior (see environmental psychology).

Since that period, behavioural geography has continued to diversify, even if its position has been less elevated than in the 1960s and 1970s when many disciplinary leaders worked in this sub-discipline. More recent research has included analysis of environmental learning, spatial search, developmental issues in spatial cognition and cartography and Golledge’s (1993) important work with the disabled and sight-impaired (see disability). But some of the lustre has left the field. In part, this may be related to the methodological sensibilities of post-positivist human geography. In part, it is due to the growing conviction of the inherently socialized nature of geographical knowledge, which challenges the individualism of psychological models. In part, it emanates from a suspicion of the adequacy of an epistemology of observation and measurement that may leave unexamined non-observable and non-measurable contexts and ideological formations. Nonetheless, behavioural geography has a continuing legacy, comprehensively itemized and integrated in the massive compilation of Golledge and Stimson (1997). DL

Berkeley School American cultural geography was dominated until the 1980s by Carl Sauer, his colleagues at the University of California at Berkeley and their students. While this type of cultural geography is no longer important in Berkeley, it remains a research tradition carried on by former Berkeley students and their students scattered throughout the world.

Arguably, no geographer had more influence on American geography in the twentieth century than Carl Ortwin Sauer (1889–1975). He received his PhD in 1915 from the University of Chicago, where he came under the influence of the environmental determinism of Ellen Churchill Semple. In 1923 he moved to Berkeley, and under the influence of the anthropologists A.L. Kroeber and R.H. Lowie was exposed to a concept of culture that was to replace his earlier environmentalist ideas. In 1925 Sauer wrote what is perhaps his best known essay, ‘The morphology of landscape’, which strongly denounced environmental determinism and suggested a method by which cultural geographers should conduct their fieldwork (Sauer, 1963b [1925]). Shortly after arriving at Berkeley, Sauer developed what was to become a life-long interest in Latin America, and there remains a strong connection with the region in the work of subsequent generations of his students. Cultural geography, for Sauer, was the study of the relationship between humans and the land (see also cultural landscape). During the latter part of his career, he pursued two broad, rather speculative historical themes. The first focused on such questions as early humans’ use of fire and the seashore as a primeval habitat, while the second explored the condition of America when Europeans first encountered it.

While giving Sauer his due, it must be remembered that most of the ideas that he introduced into the field – historical reconstruction, cultural hearth and diffusion amongst them – were current at the time in German geography (see anthropogeography) and American cultural anthropology. His intellectual debt to Friedrich Ratzel, Otto Schluter, Eduard Hahn and A.L. Kroeber was immense. Sauer and his students placed a greater emphasis upon human relationships with the physical environment than did the anthropologists, whose interests not only included human–environment relations but whose focus was on human behaviour more generally. Wagner and Mikesell (1962) identify three principal themes that define the work of the Berkeley School. The first is the diffusion of culture traits, such as plants, animals and house types. The second is the identification and evolution of culture regions through material and non-material traits (cf. sequent occupancy). The third is cultural ecology, usually also studied in historical perspective. Sauer’s persistent insistence on the importance of an historical perspective ensured that many American geographers referred to a distinctively hybrid cultural–historical geography.

It has been argued that the Berkeley School adopted a reified ‘superorganic’ conception of culture from the anthropologist A.L. Kroeber (Duncan, 1980). After the 1980s, the Berkeley School served as a counterpoint for New
Conservation Biology, a scientific journal including a learned society (the Society for the new field of conservation biology, the rapid rise to the development of a scientific infrastructure associated with the rise of biodiversity as a matter of scientific and policy concern, the term was barely used in scientific or policy communities before the 1980s. He tracks its rise to the development of a scientific infrastructure associated with the new field of conservation biology, including a learned society (the Society for Conservation Biology), a scientific journal (Conservation Biology) and an undergraduate teaching programme (at the University of California, Berkeley), all established in 1985. This body of work focused on recording and accounting for the observed and hypothesized decline in the variety of living organisms in any number of contexts – a decline represented as a human-driven process of extinction. Defined by its sense of urgency, biodiversity conservation readily took on the mantle of a global environmental crisis in both scientific and popular imaginations through such totemic (and teleogenic) spaces as the Amazonian rainforest. The rapid uptake of this new scientific agenda in the world of international environmental policy-making, centred on the United Nations, is attributed by Takacs (1996) to the influential efforts of some of its leading scientific sponsors – whom he collectively labels the ‘rainforest mafia’, notably the eminent US biologist E.O. Wilson.

Efforts to reduce the rate of decline in biological diversity associated with global and local management practices fostered under the CBD, such as Biodiversity Action Plans, are bound up with the rather different agendas of those concerned with exploiting biodiversity as a new form of natural resource (Bowker, 2000; see also GENETIC GEOGRAPHIES). Among a number of problematic tensions inherent in these management regimes, two have drawn significant and persistent political fire. First, the CBD regime sets biological diversity apart from, and at odds with, human society and activity. This is contradicted by the historical record of co-evolution between humans, plants and animals, which has left its mark, through processes such as DOMESTICATION, on the genetic and phenotypic diversity of our biological heritage today. Second, the CBD regime has generated some highly contested management arrangements, such as those permitting the slaughter of animals belonging to mammal species threatened with extinction in order to generate income to invest in the protection of the remaining species population.

As Jeffries (1997) points out in his account of the rise of biodiversity as a matter of scientific and policy concern, the term was barely used in scientific or policy communities before the 1980s. He tracks its rise to the development of a scientific infrastructure associated with the new field of conservation biology, including a learned society (the Society for Conservation Biology), a scientific journal (Conservation Biology) and an undergraduate teaching programme (at the University of California, Berkeley), all established in 1985. This body of work focused on recording and accounting for the observed and hypothesized decline in the variety of living organisms in any number of contexts – a decline represented as a human-driven process of extinction. biogeography One of the oldest sub-fields of the discipline, concerned with describing and explaining the spatial patterns of the distribution of living organisms: where they are, where they are not and why. While this field of concern has now become tightly bound up with the rise of scientific and policy effort to manage species extinctions and conserve biological diversity (see BIODIVERSITY), the study of biogeography represents an important and generative common ground between human
and physical geographers, both historically and today (see Spencer and Whatmore, 2001).

In the late nineteenth and early twentieth centuries, biogeography was a focus of analysis across disciplines such as geography, anthropology and archaeology, both for those concerned with the development of human societies and for those concerned with the distribution and viability of animal or plant populations. Cultural geographers such as Carl Sauer, for example, framed their accounts of societal development in terms of the ecological fabric of a region or landscape in which it was situated (see Berkeley school). While these concerns fell from favour in cultural geography as divisions between natural and social science perspectives and practices became more entrenched (see environmental determinism), they have gained new impetus from the popular science writing of sociobiologists such as Jared Diamond, in his account of the connections between the social and ecological collapse in the historical demise of any number of civilizations (Diamond and LeCroy, 1979). As a result, for much of the late twentieth century biogeography became, in effect, a sub-specialty within physical geography, as represented by the leading academic publication, the Journal of Biogeography. This sub-discipline has fared unevenly in the research agendas and teaching curricula of the discipline in different parts of the world.

In its twenty-first century incarnation, biogeography has regained its status as a generative common ground that takes life as its central concern, inspired by two currents (see Thrift, 2005a). The first of these is the rise of the life sciences and their potency in reworking the genetic fabric of living kinds, including humankind. The second is a renewed interest in the resources of biophilosophy that informs academic and popular concerns about the social and ecological implications of the biotechnologies that are proliferating at the interface between life and computer sciences (see Greenhough and Roe, 2006). Between the policy investment in biodiversity and the intellectual re-investment in the question of life, biogeography has become an important focus of transdisciplinary work between social and natural scientists.

**biophilosophy** A term associated with a long history of deliberations in Western thought from Aristotle, through natural history and evolutionary theory to post-genomic biology, on the question ‘What is life?’ (Margulis and Sagan, 2000). Two aspects of these deliberations are particularly influential today in academic – and, to some extent, popular – debates about the always urgent business of living. The first is the philosophy of biology (or the philosophy of organism), in which theoretical biologists and philosophers since the nineteenth century have been concerned with elucidating the principles of organization that characterize life informed by the changing practices and paradigms of biological knowledge (see Doyle, 1997). These principles primarily concern the processes of growth, decay, reproduction, development and adaptation. Here, the question ‘What is life?’ is frequently articulated as an epistemological question about how and why the study of biology (living things) differs from other fields of study.

Biophilosophy, on the other hand, represents a critique of the philosophy of biology in the sense that it is more interested in posing the same question in ontological terms that interrogate the precarious register of ‘life’ as a means of thinking past human/animal/machine categorical divisions. In this, it is less concerned with describing the universal essence of life than with tracing through its ceaseless multiplicity. Here, the focus is on the network of relations that always take the living organism outside itself and the morphogenetic impulses of replication and differentiation, multiplicity and singularity through which the flux of worldly becomings takes, holds and changes shape. It is now most closely associated with a ‘vitalist’ current that runs through Leibniz and Spinoza, Bergson and Whitehead to Deleuze (see Ansell-Pearson, 1999), and is concerned with the life force that ‘insinuates itself into the habits and repetitions of matter without becoming contained by materiality’ (Bergson, 1983 [1907], p. 126). This is one of a number of important threads weaving through non-representational theory that has become so influential in geography and other social sciences over the past five years or so.

**biopolitics, biopower** Terms coined by French philosopher Michel Foucault in his writings on medicine, discipline and sexuality (see Foucault, 1978 [1976], 2003 [1997], 2008 [2004]), which refer to power over life. Foucault traces the emergence of this particular practice to Europe in the seventeenth century, where instead of political rule being primarily over territories (see TERRITORY) and only secondarily over the people within them, it moved to being over individuals and the populations of which they were part, particularly in terms of their biological and physical characteristics. Power is exercised over the individual body and the collective body of the population. Instead of the sovereign power to *take* life, this new biopower is the power to *make*, sustain or remove life. Foucault was particularly interested in how, as political rule becomes increasingly medicalized, it is simultaneously mathematicized, with the development of measures and statistical techniques. Biopower is the tool by which the group of living beings understood as a population is measured in order to be governed, which is in turn closely connected to the political rationality of liberal democracy (see GOVERNMENTALITY). Under the broad term of biopower, Foucault examined a range of institutional practices and knowledges, including public health, housing campaigns, mechanisms for control of disease and famine, sexual behaviour, work patterns, and the treatment and organization of social, sexual and physical abnormality. His writings on this topic are part of a wider project understanding rationalities of government and the birth of the modern subject, and are interested in how power produces and shapes individuals as subjects of knowledge.

Since his death, there have been several significant extensions of Foucault’s theses. Although most of his work concentrated on Europe, his lectures on race (2003) have proved influential in thinking about colonial and post-colonial modalities of power and political violence, including war (see Stoler, 1995; Agamben, 1998; Mbembe, 2003). Several scholars have focused on the bio-political implications of contemporary biomedical and genomic research for the intensifying medicalization of society (see Rabinow and Rose, 2006b; Rose, 2006b: cf. MEDICAL GEOGRAPHY). As their work shows, developments in the life sciences now spiral far beyond questions of health to address species-being, and this has prompted several scholars to argue that security practices are being driven by a ‘toxic combination’ of GEOPOLITICS and biopolitics (Dillon, 2007; Dillon and Lobo-Guerrero, 2008).

An important stream of work on contemporary biopolitics seeks to show how the advance of particular techniques, notably biometrics, has profound political and politico-geographical consequences. Biometrics – literally the measurement of life – takes unique physical or behavioural traits such as DNA, fingerprints, iris scans or gait (the manner of walking) in order to build up a profile of an individual to enhance the workings of security systems. Much work has been done to extend these insights in analyses of the ‘war on terror’ and its derivatives (see TERRORISM) (Amoore, 2006; Reid, 2006; Dauphinee and Masters, 2007; Gregory, 2008a).

**bioprospecting** The exploration, collection and testing of biological materials in search of genetic, biochemical, morphological or physiological features that may be of value for commercial development. In certain senses it is an extension of age-old practices by which people have learned to benefit from their biophysical (and especially plant) environments. However, the ‘social and spatial dynamics’ (Parry, 2004) that underlie such activity have changed so dramatically in the past 30 years that bioprospecting can today be most usefully regarded as a significantly new articulation of that entanglement.

Specifically, three related but distinguishable developments have provided new opportunities for business and science to come together to detach biological materials and associated knowledges from their contexts, so as better to exploit them elsewhere. First, a series of economic developments has served to make bioprospecting profitable. With the emergence of BIODIVERSITY as an organizing trope and its framing as a valuable resource through the rhetoric of ‘green developmentalism’, the notion of ‘selling nature to save it’ has become legitimized. Second, a series of technical developments has served to make bioprospecting practical. In particular, the transformation of biology associated with the emergence of information technologies has made the manipulation of the genetic code of organisms the basis of its value. Finally, a series of developments in international PROPERTY
Attention is focused on nation-states and their disease statuses. These regional disease zones sometimes map on to other distinctions between North and South or Rich and Poor, mappings that are far from accidental and not without consequence (Davis, 2005). Within the state, specific sites are earmarked for bio-security measures: these include airports, seaports and increasingly farms (Donaldson and Wood, 2004). Second, there are the attempts to reduce the effects of invasive species on so-called indigenous flora and fauna (Bright, 1999). Third, there are the attempts to reduce the risks of microbiological materials being used as weapons. All three practices link together geopolitics and biogeography, throwing up real tensions between movement and stasis, nations and natures (Clark, 2002).

**biotechnology** The term is perhaps most usefully defined by a phrase as simple as ‘the uses of life’ (to quote the title of one history of the concept: see Bud, 1993). Those searching for more technically precise versions should refer to Bains’ (2003) A–Z on the subject. Although vague, this formulation has the virtue of getting across two of the more important things about biotechnology; namely, that it is both a very broad term and one that is confused and contested. Starting with the latter point, when one reviews the literature on the subject, it swiftly becomes apparent that there is nothing like an agreed definition of biotechnology. For some the notion covers everything from the ancient art of brewing through plant breeding and chemical engineering all the way to modern techniques of genetic manipulation, because all of these activities result from a coming together of human ingenuity, technical intervention and biological materials. For others, biotechnology is a frontier technology that should restrict the term to only the most recent elements of this long history; namely the proliferation of technical possibilities in the late twentieth/early twenty-first century around the convergence of an informational biology, a neo-liberal economic context and extensive legal protections on intellectual property. What is perhaps most significant about these competing positions is how they are mobilized during the many debates pertaining to biotechnology. One hears more of the former if the aim is reassurance and when long track records of safety are involved and more of the latter if the aim is to boost or debunk the technology by invoking its

**bioregionalism** An ecological philosophy and movement advocating the new ecological politics of place, born in San Francisco in the 1970s. Bioregions are defined by two kinds of mapping. First, the tools of climatology, geomorphology and natural history are used to map ‘geographic terrains’ with distinctive ecological characteristics. Second, descriptions of sense of place or ‘terrains of consciousness’ by those who live within them refine the boundaries of these bioregions. Both the approach and practice of bioregionalism have been widely criticized as analytically and politically misconceived in the context of global social and environmental problems and processes.

**biosecurity** Biosecurity is a state and intra-state response to the cross-boundary movements of non-human living things, particularly those organisms that are considered a threat to human, ecological and economic welfare. It has at least three elements. First, there is the attempt to manage the movements of pests and diseases (cf. disease, diffusion of).
revolutionary novelty. Both accounts can be heard at the same time (as in some discussions of GM crops in the USA) when the aim is to make products appear at once ‘substantially equivalent’ to what has gone before and radically new and worthy of patents and payment. Even if one sticks with the restricted take on biotechnology, the term is used to cover a diverse range of activities. The colour-coded categorization of biotechnology in common use gives some sense of this:

1. Red signifies biotechnology as applied to medical processes. This can include the genetic modification of bacteria and yeast in the development of drugs or the direct manipulation of a person’s genome in an attempt to prevent or cure disease.
2. Green signifies biotechnology as applied to agricultural processes. Most notably (and controversially), this includes the development of transgenic plants specifically designed (for example) to express or be resistant to a certain pesticide.
3. White (sometimes) grey signifies biotechnology as applied to industrial processes. Examples here include growing organisms engineered to produce a useful chemical, or bacteria that help break down certain chemicals (as used to clean up oil spills).
4. Blue, finally, signifies biotechnology as applied to aquatic, coastal or marine processes. Little used as yet but a rapidly expanding field, applications here focus on extracting useful substances from water-dwelling bacteria and other organisms.

Biotechnology in all its hues has long been identified as an area that provides both challenges and opportunities for geography (Katz and Kirby, 1991). Following a series of more recent provocations (e.g. Castree, 1999c; Whatmore, 1999a; Spencer and Whatmore, 2001), a body of literature is now finally emerging within the discipline that is taking these opportunities and challenges seriously – see, for example, the articles collected in special issues edited by Bridge, Marsden and McManus (2003) and Greenhough and Roe (2006). Even more encouragingly, the best of this work is eschewing the familiar temptations of economic reductionism or technological determinism in favour of developing conceptually informed, empirically rich accounts of what happens when something new (an object or a technique) is added to an already full world. Thus attention is paid at once to the new spaces of transformation and circulation involving biotechnology and also the questions of coexistence of existing and novel ways of life that such new spaces raise.

**blockbusting**

A tactic engaged by American land speculators to buy housing units and then rent or sell them at inflated prices. In cities such as Chicago, industrialization, African-American migration to northern cities and racial segregation resulted in a growing, but spatially contained, African-American population (Philpott, 1991 [1978]). In White neighbourhoods adjacent to this African-American ghetto, real estate agents would sell or rent a vacant unit to an African-American household, then use fear tactics about lower home values and racial change to persuade white homeowners to sell. Units would then be sold or rented to African-American households at grossly inflated prices. The result spatially expanded the ghetto (Hirsch, 1983).

**body**

A rapidly growing field within geography deals with social and spatial conceptions of the human body – often located in the tension between the body as a social and a biological phenomenon. This upsurge of interest in the body does not confine itself to geography, but occurs all over the social sciences and humanities. The background might be found in a mixture of circumstances. Some authors refer it to changes in the cultural landscape of late modernity, involving a rise of consumer culture and self-expression. Others regard it primarily as a theoretical intervention, rectifying a former deficiency in social theory. And for still others, feminism is held responsible for putting the body on the intellectual map. Initially, there is a division in the social theory of the body, one that is often attributed to Maurice Merleau-Ponty and Michel Foucault, respectively. On the one side stand analyses of the body as lived, active and generative, and on the other side studies of the body as acted upon, as historically inscribed from without. Still other approaches are informed by psychoanalytic theory. These different approaches are mostly

translated into geography by means of feminist writings. A major source is Judith Butler’s Foucauldian theory of performativity, understood as ‘the reiterative and citational practice by which discourse produces the effect that it names’ (1993a, p. 2). For Butler, the body is socially constructed, embodying possibilities both conditioned and circumscribed by historical convention. Moi (1999), following Simone de Beauvoir, forwards a concept of the body as a ‘situation’ – a situation amongst many other social ones, but fundamental in the sense that it will always be a part of our lived experience and our coping with the environment. Grosz (1994) argues for a sexed corporeality in which alterity is constitutive of (material, psychological and cultural) bodies and emphasizes the volatile boundaries of the bodies, permeated by bodily flows and fluids (see also abjection).

Within geography, the degree to which time geography dealt with the body is a contested matter, but two approaches to human geography in the 1970s and 1980s did contain traces of the body. In humanistic geography, lived and sentient body-subjects appeared, and in Marxist geography the body was implicitly present in notions of the material reproduction of labour power. The real upsurge of interest in the body, however, occurred in the 1990s, not surprisingly led by feminist geographies. This work can be summarized around three themes.

The first one is the body as the geography closest in. It includes the spatiality of the body, drawing on phenomenology or on Lefebvre’s theory of the production of space, including both the generative spatializing body and the historical confinement of the body in abstract space (Simonsen, 2005). Mostly, however, the literature has dealt with the inscription of power and resistance on the body, concurrently involving issues of performativity, body politics and the body as a site of struggle. Due to her processual, non-foundational approach to identity, many have incorporated Butler’s notion of performativity into their work on the intersections between gender, sexuality, space and place – for example, the performance of gay skinheads and lipstick lesbians in sexualized spaces (Bell, Binnie, Cream and Valentine, 1994), or gendered performances of work identities within the finance industry (McDowell and Court, 1994). The notion is, however, contested. For example, Nelson (1999) criticizes the translations of the language of performativity into geography for not being aware of what she sees as its radical representational notion of body and subjectivity, in this way initiating a lively discussion of the limits of performativity.

The second, related, theme is other bodies. Taking off from the insights of feminism, post-structuralism and post-colonialism, it tackles the necessity of acknowledging differences and power in embodiment. The body is central in the process where dominant cultures designate certain groups (disabled, elderly, homosexual, fat, female, people of colour, people of other nations and so on: see ageism; disability; ethnicity; homophobia and heterosexism; racism; sexuality) as Other. Subordinate groups are defined by their bodies and according to norms that diminish and degrade them as ugly, loathsome, impure, deviant and so on, while privileged groups, by imprisoning the Other in her/his body, are able to take on the position as disembodied subjects. This ‘scaling of bodies’ has provoked analyses that on the one hand expose processes of domination and socio-spatial exclusion (Sibley, 1995) and on the other explore struggles for recognition and appropriation of space. A well-developed area within this group is queer theory, which explores negotiations and conflicts over symbolic and material spaces marked by exclusionary imperatives and politics.

Third, philosophies on the body have inspired theorists to dismantle dualisms that have long troubled Western thought and culture. Primarily, the mind/body dualism is addressed, subsequently leading to the ones of subject/object, culture/nature, sex/gender and essentialism/constructionism. Feminists have shown how such dualisms have been strongly gendered, connecting the female body to nature, emotionality, non-consciousness and irrationality. Substantially, the dismantling of dualisms has worked as a means to expose the instability and fluidity of bodily-ascribed identities. Epistemologically, it has enforced the acknowledgment that not only the objects of analysis but also the geographer her/himself are embodies. Many geographers have, at least in principle, adopted the notion of embodied or situated knowledge as a substitute for decontextualized, disembodied, ‘objective’ knowledge.

As pointed out by several authors (e.g. Callard, 1998), the first wave of body-literature within geography favoured particular ways of understanding the body. A wealth of studies was devoted to body-inscriptions, body regimes and discourses on bodies, while practices of
material and fleshy bodies attracted less attention. This gap has, however, started to be filled: Longhurst (2001) implements Grosz’s theory of the volatile materiality of the body through ideas of body boundaries, body fluids, ABJECTION and (im)pure spaces; studies on illness, impairment and disability explore ‘body troubles’ in everyday coping with the environment; and theories of practice and non-representational theory focus on moving bodies and the performative and material nature of embodiment. The latter also dissolves the distinction between the human and non-human, the organic and non-organic (see also CYBORG).

border A form of boundary associated with the rise of the modern nation-state and the establishment of an inter-state geopolitical order, founded – most famously with the foundational myths of the 1648 Treaty of Westphalia (Teschke, 2003) – on the political norms of national states claiming and using terror to control TERRITORY (as the etymology is also sometimes interpreted: see Hindess, 2006). Both on maps and on the ground, borders make spaces of national SOVEREIGNTY, and are thus key sites where the ‘inside versus outside’ distinctions of TERRITORIALITY and modern international relations are at once reproduced, reinforced, contested and transcended (Walker, 1993; Agnew, 2003a). Thus, as the French philosopher Etienne Balibar suggests, borders are ‘overdetermined, and in that sense, sanctioned, reduplicated and relativized by other geopolitical divisions’ (Balibar, 2002, p. 79). It is for this same reason that political geographers have increasingly focused on what many call ‘re-(b)ordering’ (Newman, 2002; Kolossov, 2005; Van Houtum, 2005; Van Houtum, Kramsch and Zierhofer, 2005).

Borders appear in geopolitical discourses that at once reproduce and reinforce the nation-state. In media ranging from the legal and pedagogic to the prosaic and banal – from court-case cartography, school maps and museums, to murals, cartoons and even weather forecasts – IMAGINATIVE GEOGRAPHIES script and thereby sanction the divisions of national borders (Paasi, 2005a; Sparke, 2005; Anderson, 2006a; Painter, 2006). These cultural geographies of border construction in turn inform the actual enforcement of borders on the ground through both social practices and state practices of border control (Nevins, 2002; Coleman, 2005). Many border-buttressing social practices are xenophobic, and remain animated today in many parts of the world by provincial, racist and/or masculinist fantasies about foreign ‘floods’ overwhelming homeland defenses (see Theweleit, 1987; Darian-Smith, 1999; Wright, 1999b; Price, 2004). However, while such social reinforcement continues to reduplicate twentieth-century divisions produced by liberal regimes of ethno-racial and sexual GOVERNMENTALITY, contemporary state practices of border control are simultaneously being shaped by the new CLASS divisions and related but context-contingent recombination of neo-liberal governmentality with neo-liberal GOVERNANCE. It is in this way that the borders inside and around various free trade regions are being both softened and hardened simultaneously. Within the EU (Sparke, 2000a; Walters, 2002), the NAFTA region (Bhandar, 2004; Coleman, 2005; Gilbert, 2007), and diverse, smaller scale cross-border free market development zones (for which the Malaysia–Indonesia–Singapore growth triangle is the prototype; see Sparke, Sidaway, Bunnell and Grundy-Warr, 2004), governments are attempting to bifurcate border management: facilitating fast crossing for business travellers and increasing punitive policing of working class ‘others’ deemed dangerous to the neo-liberal free market order.

The neo-liberal class-divided relativization of borders is not happening in the same way everywhere. Within the NAFTA zone there remain all sorts of informal cross-border economies (see Staudt, 1998), and in Europe, while the old Cold War East German/West German border has turned into an Ossie/Wessie social class divide (Berdhal, 1999), the Iron Curtain border of the COLD WAR past has not been bifurcated but, rather, subsumed into an EU growth and integration zone (Scott, 2002; Smith, 2002a). And these kinds of complexities seem minor in contrast to the ways in which the new border between Israeli-occupied enclaves and Palestinian-controlled parts of the West Bank reduplicates the geopolitics of religious and ethnic divisions with a vengeance, all the while relativizing the old Green Line and hopes of a ‘good border’ by imposing a monumental and militarized class divide with the new concrete curtain of the colonial present (Gregory, 2004b; Newman, 2005; see also Falah and Newman, 1995).
Contextual contingencies noted, the emergence of a transnational business class with increasingly global RIGHTS to own PROPERTY, make contracts and move freely has clearly been marked at and on borders the world over. State border management is becoming increasingly transnationalized in its global coordination, with border-relativizing reliance being placed on individualized biometric codes rather than traditional national passports (Adey, 2004; Sailer, 2007). Meanwhile, as the US continues to wage its so-called war on terror, the soft-COSMOPOLITANISM of the border-crossing kinetic elites seems set to be accompanied by the creation of a carceral cosmopolitanism for those border-crossers deemed a threat to the free world (Sparke, 2006). Within these developments we can see—to return to a term of Balibar's—the 'other scene' of borders today: a scene in which the sovereignty system supposedly established at Westphalia is superseded by a new kind of global 'territory', delinked from the nation-state and its geographical borders (cf. Kelly, 2005; Hindess, 2006).

**borderlands** A key term in two contemporary literatures, the concept-METAPHOR of borderlands is employed alternatively as either a research re-focusing concept for scholars who study cross-border regional development (e.g. Pratt and Brown, 2000), or as a meaning remaking metaphor designed to disrupt normalizing notions of NATION and the NATION-STATE (e.g. Anzalduá, 1999). Both uses of the term refer back to the geographical REGIONS surrounding international BORDERS, and both also frequently involve attempts to describe the lives and IMAGINATIVE GEOGRAPHIES of people whose daily practices, economic activities and cultural connections cross the borders that define nation-states. But whereas research on cross-border regional development tries to draw analytical comparisons between different models of borderlands GOVERNANCE, work on the multiple meanings of borderlands seeks to find antidotes to nationalist chauvinism and attendant forms of ethnic absolutism in the cross-cultural intermixing of everyday borderland life. This does not mean that the disruptive uses of the term are always focused on just cultural HYBRIDITY. There are some brilliant borderlands studies that underline how everyday economic, social and political ties across border regions are just as disruptive of normative assumptions about nation-states and related forms of gendered, racialized and/or ethnicized identity (Staudt, 1998; Berdahl, 1999; Darian-Smith, 1999, Price, 2004). Likewise, there are also many usefully sobering studies that show how, in all too many cases, such disruptions still continue to be exploited, controlled and/or destroyed through various combinations of state- and market-mediated VIOLENCE (Wright, 1999b; Nevins, 2002; Lindquist, 2004; Coleman, 2005).

Inspired in part by the studies that highlight how POWER relations become particularly evident in borderlands, and catalysed by an emerging governmental interest in cross-border regional planning, there has been a recent explosion of articles and edited volumes on border-region development that are increasingly attuned to the ways in which such regions make manifest diverse political geographies of reterritorialization (Eskelinen, Likanen and Oksa, 1999; Perkmann and Sum, 2002; Nicol and Townsend-Gault, 2005; van Houtum, Kramsch and Ziehofer, 2005). While a few contributions to this literature seek to emulate a corporate TRANSNATIONALISM and promote branded borderlands for capitalist development (e.g. Artibise, 2005), other works critically chart the ways in which such place promotionalism feeds into and out of the cross-border regional entrenchment of NEO-LIBERALISM (Perkmann, 2002; Nicol and Townsend-Gault, 2005; Sparke, 2005). But borderlands continue to be shaped by a multitude of other forms of reterritorialization too, and whether these take geographical shape as geopolitics (see Scott, J.W., 2002, 2005b; Brunn, Watkins, Fargo and Lepawsky, 2005; Edwards, 2005), hybrid natures (Sletto, 2002; Fall, 2005) or post-colonial sovereignties (Mbare, 2000; Kramsch, 2002; Sidaway, 2002; Sparke, Sidaway, Bunnell and Grundy-Warr, 2004), borderlands provide usefully prismatic lenses on to the changing geography of power in the context of GLOBALIZATION. MS

**Boserup thesis** Classical political economists, and Malthus and Ricardo in particular, developed in the early stages of DEMOGRAPHIC TRANSITION in Europe a macroeconomic theory of the relations between population growth and agriculture. Ricardo (1817) distinguished between intensive and extensive agricultural expansion: **extensive expansion** presumed the extension of cultivation into new lands that were marginal and therefore subject to diminishing returns to labour and capital, whereas **intensive expansion** enhanced the output of existing lands through the application of better
weeding, fertilizer, drainage and so on, which was also subject to diminishing returns to labour and capital. Ricardo, like Malthus (1803), assumed that population growth increases would be arrested by a decline in real wages, by increases in rents and by per capita food decline.

There is a third form of intensification that rests upon the deployment of the increasing labour force to crop farmland more frequently (i.e. to increase the cropping intensity or to reduce the fallow). The reduction of the period of fallow (the period of non-cultivation or recovery in which the land is allowed to regenerate its fertility and soil capacities) was a major way in which European agriculture increased its output during periods of population growth, as observed at the time when Ricardo and Malthus were writing. Fallowing does not imply poorer or more distant land, but as the fallow length is reduced greater capital and labour inputs are required to prevent the gradual decline of crop yields and the loss of fodder for animals.

Esther Boserup (1965, 1981) made fallow reduction a central plank of her important work on agrarian intensification. While fallow reduction is also likely to yield diminishing returns, these are more than compensated for by the additions to total output conferred by increased cropping frequency.

In the eighth century the two-field system predominated in Western Europe, but by the twelfth and thirteenth centuries the three-field system had come to displace its two-field counterpart in high-density regions (see field system). By the eighteenth and nineteenth centuries, the fallow had begun to disappear entirely. Boserup (1965) saw this falling off as the central theme in agrarian history and the centrepiece around which the Malthusian debates over overpopulation and famine ultimately turned (cf. malthusian model). In her view, output per person–hour is highest in the long-fallow systems – for example, the shifting or swiddening systems of the humid tropical forest zone, in which diverse polycropping of plots for one or two seasons is then followed by a fallow of 15–25 years (depending on local ecological circumstances: cf. shifting cultivation) – and population growth is the stimulus both for reduction in fallow and the innovations associated with intensified land use.

Boserup envisaged a progressive series of fallow reductions driven by the pressure of population (and the threat of exceeding the carrying capacity). Long-fallow systems that are technologically simple (associated only with the digging stick and the axe) are displaced by bush fallow (6–10 year fallow) and short fallowing (2–3 year fallow) in which the plough is a prerequisite. Annual, and finally multiple, cropping appear as responses to continued population pressure. Across this progression of intensification is a reduction in output per person–hour, but a vast increase in total output. The shift to annual and multiple cropping also requires substantially new forms of skill and investment, however, which typically demand state-organized forms of investment and surplus mobilization. Boserup saw much of Africa and Latin America as occupying an early position in a linear model of intensification in which output could be expanded by fallow reduction. The ‘Boserup thesis’ refers to the relationship between population growth and agrarian intensification, measured through fallow reduction and a decreasing output per person–hour.

Implicit in the Boserup thesis, although she did not develop these implications, is the changing role of land tenure, the increasing capitalization of the land and more complex forms of state–society interaction. Indeed, Boserup’s work has been taken up by a number of archaeologists and anthropologists, who have charted patterns of state formation and social development in terms of agrarian intensification.

Boserup’s anti-Malthusian theory lays itself open to all manner of charges, including a non-linear form of techno-demographic determinism and a general lack of attention to the ecological limits of intensification (Grigg, 1980; cf. teleology). It is not at all clear how or whether Boserup’s thesis can be applied to market economies. Indeed, her thesis does not seem to be much help, for example, in the English case: in its essentials, the agricultural technology of the eighteenth century (the Norfolk four-course rotation) had been available since the Middle Ages, and although the eighteenth century was a period of population growth, the previous period of sustained demographic growth from the mid-sixteenth century had witnessed no intensification as such (Overton, 1996: see agricultural revolution). Processes of intensification are naturally on the historical record and the reduction of falling in the third world – whether driven by demographic growth or not – has been and continues to be documented (see Guyer, 1997). But intensification is a socially, culturally and politically complex process. To the extent that fallow reduction
involves someone working harder and differently, the question of who works, when and for what return (a question played out in terms of age, gender and class in the peasant household) is not posed by Boserup. Here, newer work on household dynamics has more to offer (Carney and Watts, 1990).

boundary At once a geographical marker and a geographical maker of regulative authority in social relations. As markers of authority, boundaries range considerably in scale, significance and social stability. From international boundaries that mark the borders between nation-states to the barbed-wire boundaries that mark the perimeters of export-processing zones, to the racially, religiously and/or sexually exclusive boundaries that still mark the privileged places of decision-making occupied by straight, white, Christian, men of property in America, boundaries take many different forms. But whether boundaries are the product of international conventions, economic expediency or cultural conservativism, a key point highlighted in the work of geographers is that boundaries are also geographically constitutive makers as well as markers of regulative power relations. In other words, international boundary lines actively operate to create and consolidate the global norms of nation-state territoriality and the national identities forged under the resulting aegis of state sovereignty (Paasi, 1996). Barbed-wire fences around export-processing zones serve directly to carve off such spaces from wider political geographies of civil interaction, labour organization and democratic oversight, thereby depriving workers inside of numerous citizenship rights (Klein, 2002). And the invisible but often impenetrable boundaries referred to by terms such as the ‘glass ceiling’ also clearly help enable and enforce spaces of privileged authority (Berg, 2002).

Nevertheless, not all boundaries create their regulative effects through binary ‘us–them’ partitions. In many cases of state boundary drawing inside modern nation-states – including the boundaries drawn to delineate electoral districts, schools districts, police districts, public health districts and so on – the act of inscribing a boundary on a map and enforcing it with routinized bureaucratic state actions on the ground helps create the larger singular effect we call ‘the state’. As Timothy Mitchell (1991) has argued, following Foucault, state effects can thereby be said to emerge through the everyday acts of spatial organization created by government. This is also no doubt why the publishers of a book such as Seeing like a state (Scott, J.C., 1998b) saw fit to put an everyday image of a distinctly right-angled turn in a road on the cover, an apparently arbitrary turn, presumably produced by some jurisdictional boundary marked on a state map. But since a scholar such as Mitchell argues vis-à-vis traditional state theories (including the highly anthropomorphized and sovereigntist kind advanced by Scott), the lesson of such geographical boundary making is not that there is a king-like state whose boundary-drawing is a sign of top-down state dominance. Rather, the point is that along with all the state practices that the boundaries enable, the process of boundary drawing is itself a disciplinary dynamic that helps consolidate the authority of the state. Mitchell applies this argument most directly to theorizing the emergence of nation-state power, but it can equally be argued to apply to sub-national and transnational forms of state-making too (Sparke, 2005). Once examined in such venues as courtrooms and free trade tribunals, boundary drawing can also be seen as a highly contested mediation process through which the power relations of everyday social life, and the power relations of government themselves begin to reappear as if divided by a stark state/society boundary. However, as work by geographers on everything from electoral gerrymandering (Forest, 2005) to community policing (Herbert, 2006) shows, the concept of such a clear-cut state/society boundary is better reinterpreted as a site of fraught political–geographical struggles, struggles which in the very process of blurring the abstract state–society distinction often end up creating new jurisdictional boundary lines on the ground.

Brenner thesis A thesis proposed by historian Robert Brenner (1976) as a contribution to a running debate within primarily Marxist scholarship about the transition from feudalism to capitalism. Brenner emphasized the ways in which class, and more specifically property relations, served as a ‘prime mover’ of economic change. His basic premise is that the relationship between landlord and tenant was exploitative and depended on ‘non-economic compulsion’. Thus relations of production in thirteenth- and fourteenth-century England were dominated by the institution of serfdom, which was buttressed by the manorial system and the common law that excluded serfs from access to royal courts (which were reserved for those who were legally free). Hence lords could act arbitrarily
in their dealings with their unfree tenants. The power of this exploitative relationship provided a ready explanation for low and declining productivity within the peasant sector before the Black Death, which in this analysis has little if anything to do with a population-resource imbalance as proposed in the POSTAN THESIS. Not only was this relationship inimical to the maintenance of effective husbandry within the peasantry, but it also led to a build-up of tenants on the land, since it curtailed the migration of serfs to areas where their labour could be more effectively deployed.

The struggle between lords and peasants had different outcomes in different regions, which Brenner argues accounts for macro-geographical variations in the move towards agrarian CAPITALISM in EUROPE: in England lords were the victors, since tenants never gained absolute property rights, whereas in France peasants were far more successful. Brenner contends that landlord capacity was diminished in the period of demographic depression after the Black Death, but that when population growth resumed in the sixteenth century, lords who still retained their power were able to evict peasant producers and install entrepreneurial tenants who farmed larger holdings with the increasing use of wage labourers. In this way, Brenner explains how agrarian capitalism emerged earlier in England than in the rest of Europe.

The thesis has been subject to considerable debate in history and HISTORICAL GEOGRAPHY (Aston and Philpin, 1985). Many now claim that serfdom did not operate in the manner proposed by Brenner, since custom gave unfree tenants much protection from market forces – and, indeed, benefited this group in the period of price and rent inflation in the thirteenth and early fourteenth centuries (Hatcher, 1981; Kanzaka, 2002; Campbell, 2005). Furthermore, English customary LAW may have been greatly influenced by the common law to the extent that lords were in no position to operate their courts arbitrarily to their advantage (Razi and Smith, 1996b). While Brenner purports to treat the landlord–tenant relationship as an endogenous component, he is reluctant to admit the impact of exogenous forces associated with demographic change driven by epidemiological movements that have little to do with human agency (Hatcher and Bailey, 2001). Others have argued that changes in the distribution of land and the stimulus of land markets came as much from within the tenantry as it did from landlord initiatives (Glennie, 1988; Hoyle, 1990; Smith, 1998b). Likewise, it has been claimed that middling sized owner-occupied farms were the principal source of an early modern AGRICULTURAL REVOLUTION (Allen, 1992). Even within Marxist circles, there are those who would stress the emergence of a WORLD SYSTEM in which international trade and colonial expansion served to advantage England and its near neighbour Holland, leading to the emergence of large urban centres, which in turn stimulated demand for foodstuffs and the move towards capitalist FARMING. Such arguments have loomed large in the writings of Pomeranz (2001), who also stresses the importance of access to the ‘ghost acres’ of the AMERICAS as fundamental to English economic success.

Aston and Philpin (1985); Brenner (1976).
cadastral mapping  A system of surveying and recording the boundaries, structures and salient features of land parcels in order to confirm ownership, support the buying and selling of land, promote the assessment and taxation of landed property, and delinate the territorial privileges of tenants and others assigned limited rights. In addition to its traditional role in the commodification of land, a modern multi-purpose cadastre provides an efficient framework for urban and regional planning, land-use regulation, and the management of publicly and privately owned infrastructure such as sewers and distribution pipelines for water and natural gas (National Research Council Panel on a Multipurpose Cadastre, 1983). Where data-sharing arrangements and a common plane-coordinate system permit, a geographic information system can readily integrate land-record data with street-address information, terrain data, census results, and environmental and natural-hazard data, including flood-zone boundaries.

Allied with notions of private property, cadastral maps are among the oldest cartographic forms (see cartography, history of), in use at least as early as 2300 BCE, when the Babylonians described land boundaries and structures on clay tablets (Kain and Baigent, 1992, p. 1). The Egyptians and the Greeks were less inclined to map property surveys than the Romans, who used maps to tax private holdings and differentiate them from state lands. The collapse of the Roman Empire in the fifth century AD temporarily ended property mapping in Europe, but Renaissance capitalism revived the map as a management tool for private estates and precipitated the development of intricate state cadastres during the enlightenment. Cadastral mapping was essential to European colonization of the New World, where land grants and orderly settlement depended on map-based land registration (see colonialism).

Cadastral mapping has an important role in the third world, where comprehensive land-record systems can promote land reform by validating traditional holdings, minimizing boundary disputes, promoting conservation of natural resources, and reducing land fragmentation, which can undermine agricultural productivity. However promising, cadastral reform easily fails if poorly planned or not fully implemented (Ballantyne, Bristow et al., 2000).

In the more developed world, online cadastres have heightened the innate conflict between personal privacy and open access to public records (Monmonier, 2003). Public access to cadastral information is a fundamental right in the USA and other countries in which local officials base evaluations of taxable real property on the parcel descriptions and sale prices of nearby or similar properties. Without access, citizens cannot judge the fairness of their assessments and present an informed challenge to an inequitable evaluation. By making transaction data far more readily available, the internet has undermined the expectation of privacy among buyers reluctant to disclose their purchase price. Even so, benefits clearly trump injuries insofar as ready disclosure promotes a more knowledgeable real-property market and arguably fairer tax assessments.

camp  ‘The hidden matrix . . . of the political space in which we are living’ (Agamben, 1998, p. 166). Agamben’s controversial thesis focuses on the juridico-political structure (or nomos) that produced the concentration camp. These camps were introduced by European colonial regimes in Cuba and South Africa at the close of the nineteenth century, but Agamben is most interested in those established by the Nazis during the Second World War. Unlike many writers, Agamben does not see these as aberrations from the project of modernity – paroxysmal spaces – but, rather, as paradigmatic spaces. What took place in them was made possible, so Agamben claims, because the camps were materializations of the space of exception (see exception, space of) in which the state withdrew legal protections from particular groups of people (Jews, gays and Romanies among them). By this means, millions of victims of fascism could be reduced to bare life (cf. Agamben, 1999). But the camp is neither peculiar to fascism
nor limited to an enclosed space. For Agamben, ‘the camp is the space that is opened when the state of exception begins to become the rule’, and he insists that ‘we find ourselves virtually in the presence of a camp every time such a structure is created’ (Agamben, 1988, p. 174). Seen thus, it is by no means absent from liberal-democratic societies. Hence Agamben draws formal parallels between concentration camps and the sites where states now hold illegal immigrants or refugees (cf. Perera, 2002), and he claims that the juridico-political structure through which prisoners taken during the ‘war on terror’ are held confirms that the global generalization of the state of exception is intensifying (cf. Gregory, 2006b, 2007).

‘The normative aspect of law can be thus be obliterated and contradicted with impunity,’ he continues, through a constellation of sovereign power and state violence that ‘nevertheless still claims to be applying the law.’ In such a circumstance, he concludes, the camp has become ‘the new biopolitical nomos of the planet’ (see biopolitics) and ‘the juridico-political system [has transformed] itself into a killing machine’ (Agamben, 1988).

That Agamben’s thesis is concerned with the metaphysics of power and the logic of juridico-political structures needs emphasis. Bernstein (2004) objects that what then becomes lost from view is the complex of institutions, practices and people through which these reductions to bare life are attempted: in the case of Auschwitz, for example, the gas chambers, the guards, the huts, the watch-towers, the railways, the police, the round-ups — in short, the whole apparatus of violence that produced the holocaust. But this is precisely Agamben’s point: ‘Instead of deducing the definition of the camp from the events that took place there, we will ask: What is a camp, what is its juridico-political structure, that such events could take place there? In his view, the urgent political task is to disclose ‘the juridical procedures and deployments of power by which human beings could be so completely deprived of their rights and prerogatives that no act committed against them could appear any longer as a crime’ (1998, pp. 166, 171). Even so, it is not at all clear that Agamben is much interested in the details of those other ‘deployments of power’ or the spaces that are produced through them, and nor does he register the ways in which resistance to the production and proliferation of camps is mobilized.

capital In everyday parlance, capital is an asset to be mobilized by a group, individual or institution as wealth. This economic sense of capital has, according to Raymond Williams (1983 [1976], p. 51), been present in English since the seventeenth century and in a fully developed form since the eighteenth – derived from its general sense of ‘head’ or ‘chief’. Capital in this sense might be a stock of money (invested to secure a rate of return), a pension fund or a piece of property. In the broadest sense – often deployed as such by conventional forms of economics – capital is an asset of whatever kind capable of yielding a source of income for its owner (which is typically, depending on the asset and the legal rights to it, a claim on interest, on rent or on profits). In classical economics, capital was assumed to be one of a trio of factors of production (land and labour being the others), distinguished by the fact that it was produced (contra land), could not be used up in the course of production as might a resource and could be used in the production of other goods. Both Adam Smith and David Ricardo referred to a distinction between fixed and circulating forms of capital. Capital goods are already produced durable goods, available for use as a factor of production. In this classical (and indeed neo-classical) sense, capital was a stock, in contradistinction to investment over time (a flow). Implicit in all of these definitions is a twofold sense of capital being trans-historical (it applies to every society) and it posits the fact of inanimate objects (land) being generative (of income). Over the past half-century there have been many efforts to classify capital beyond its narrow economic meaning. The list is now very long (see Putnam, 2001; Bourdieu, 2002): human capital (skills, competences, education), cultural capital (the symbolic and hermeneutic class powers deployed in the political and economic realm), social capital (the social networks and social agencies deployed in economic development), political capital (political resources deployed within different domains of politics – for example, the state, the family) and finance capital (originally developed a century ago by Hilferding to address the increasing integration of industrial and banking enterprises).

The Marxist conception of capital stands in sharp contradistinction to these sorts of claims and to all conventional definitions. Capital is first a social form that pre-dates capitalism.
but dominates in, and is generic to, capitalism as a system of generalized commodity production. Capital is not a thing, but is a ‘social relation’ that appears in the form of things (money, means of production). Capital does indeed entail making money or creating wealth but, as Marx (1967) pointed out, what matters are the relations by which some have money and others do not, how money is put to work, and how the property relations that engender such a social world are reproduced. Capital, said Marx, ‘is a definite social production relation belonging to a definite historical formation of society which is manifested in a thing and lends this thing a specific social character’ (Marx, 1967, vol. III, p. 48). Under capitalism, capital is ‘value in motion’; that is to say, it is an expansionary social value that drives, and arises from, the production process. The process – multifaceted and unstable – by which money is converted into labour, raw materials, capital goods, commodities and back into money again is what Marx called ‘the general formula of capital’. Capital arises from the social labour organized for generalized commodity production – that is to say, a competitive system in which commodities produce commodities. The enormous complexity of the category is bound up with the ways in which the meaning of the word ‘capital’ shifts and transforms itself in Marx’s work, leading some to note that a word such as capital is bat-like: one can see in it both birds and mice.

Capital comes to dominate in a capitalist mode of production. Capitalist societies are marked by the fact that capital is socially owned and organized in particular ways – by a capitalist class. Contemporary forms of capitalism have, however, vastly complicated this class map, not least by the ways in which shareholder capital (pension funds, individual shareholders and government ownership of stock) has refigured the cartography of the ownership of capital. Geographers have largely focused on the ways in which capital as a social relation has spatial and ecological expressions – for example, the geography of accumulation of industrial districts, and the relations between value in motion and global climate change – and on the prismatic ways in which capital attaches natural characteristics to things that are socially produced (see Harvey, 1999 [1982]; Smith, 1982; RETORT, 2005).

capitalism As a word denoting a distinctive economic system, ‘capitalism’ began to appear, according to Raymond Williams (1983 [1976], p. 50) in English, French and German from the early nineteenth century (although the Oxford English Dictionary cites its first use by Thackeray in 1854). ‘Capitalist’ – as a key actor in a capitalist system – has a longer semantic history, dating back a half-century earlier, but this term too was clearly being used to describe an economic system – sketched by Adam Smith and the Scottish political economists among others – for which the word capitalism had not yet been invented. Capital and capitalist, says Williams, were technical terms in any economic system but gradually became deployed to account for a particular stage of historical development, and out of this shift in meaning crystallized the term capitalism. Marx, who did not use the term until the 1870s, was the central figure in distinguishing capital as an economic category from capitalism as a specific social form in which ownership of the means of production was centralized (through a capitalist class), and that depended upon a system of wage-labour in which a class had been ‘freed’ from property. Capitalism in this sense, again as Williams observed, was “a product of a developing bourgeois society” (1976, p. 51). The term gained some traction in the 1880s in the German socialist movement and was then extended to non-socialist writing, though its first extensive English and French usages seem to not have been until the early twentieth century. In the wake of 1917, and most especially after the Second World War, capitalism was rarely used as a descriptor by its promoters, and was deliberately replaced by such terms as free or private enterprise and, more recently still, the market or free market system (as part of the neo-liberal discourse of the 1980s and 1990s).

What, then, are the defining qualities of capitalism, understood as a distinctive mode of production? It is a historically specific form of economic and social organization and in its industrial variant can be roughly dated to mid-eighteenth century Britain, but the theorization of its conditions of possibility and its internal dynamics have necessarily been an object of intense debate. Classical political economy – Adam Smith and David Ricardo – and its Marxian critique both accepted that capitalism was a class system, that labour and capital were central to its operations, and that capitalism as a system was expansive, dynamic and unstable. These accounts fasten upon the economy – or, more properly, the political economy – and the centrality of property relations, the market–commodity nexus, the separation of the workers from the means of
production and the centralization of capitalist control under the figure of the capitalist-entrepreneur. These claims – to the extent that they reflect some common ground – are subsequently elaborated in radically different ways. Some cling to a narrow definition of economy (theorized in different ways) as central to the intellectual enterprise; others seek to link economy, culture, politics and society into a more elaborated sense – what Max Weber called a ‘cosmos’ – of a capitalist system. In general, the development and institutionalization of the critical social sciences has seen a massive proliferation of opinion – and of conceptual apparatuses – for the examination of actually existing capitalist systems.

Some of this diversity of opinion can be appreciated by a consideration of a quartet of theorists. Adam Smith, like other classical political economists, was concerned with the distribution and accumulation of economic surplus and the problems of wage, price and employment determination. Writing at the birth of industrial manufacture, the key to the Wealth of Nations (see Smith, 2003) is the concept of an autonomous self-regulating market economy described as civil society. Smith’s genius was to have seen the possibility of an autonomous civil society, its capacity for self-regulation if left unhindered and its capacity for maximizing welfare independent of state action. Smith located capitalism at the intersection of the division of labour and the growth of markets. Furthermore, in this system self-interested individuals indirectly and inadvertently promoted collective interest through the functions of self-regulating markets. The growth of commerce and the growth of liberty reinforce one another under capitalism. In its neo-classical variant, labour markets are seen as different than any commodity market and capitalist markets are assumed, if unimpeded by the state or other distortions, to function to produce a general equilibrium. Friedrich von Hayek’s (1944) account of liberal capitalism took this reasoning to its limit. Capitalism was conceived of as a unity of liberty, science and the spontaneous orders that co-evolved to form modern society (the ‘Great Society’, as he termed it). It is a defence of the liberal (unplanned) market order from which the preconditions of civilization – competition and experimentation – had emerged. Hayek, like Weber, saw this modern world as an iron cage constituted by impersonality, a loss of community, individualism and personal responsibility. But, contra Weber, these structures, properly understood, were the very expressions of liberty. From the vantage point of the 1940s this (classical) liberal project was, as Hayek saw it, under threat. Indeed, what passed for liberal capitalism was a travesty, a distorted body of ideas warped by constructivist rationalism, as opposed to what he called ‘evolutionary rationalism’. Milton Friedman (2002 [1962]), in the realm of economic theory, waged this battle from the 1960s onwards.

For Max Weber, the capitalist cosmos was guided by systems of calculability and rationality – this is what gave Western capitalism its specificity – which grew in part as an unintended consequence of Protestantism (see Weber, 2001 [1904–5]). Formal rationality produced a capitalist society characterized by large-scale industrial production, centralized bureaucratic administration and the ‘iron cage’ of capitalism that shapes individuals lives with ‘irresistible force’. Contra Smith’s roseate vision of capitalism – though always wary of the costs of class oppression, in his view dished out by corrupt government – Weber’s vision of capitalism was ultimately bleak, always operating in the shadow of the ‘totally administered society’.

Karl Polanyi was a Hungarian economic historian and socialist, who believed that the nineteenth-century liberal capitalist order had died, never to be revived (see Polanyi, 2001 [1944]). By 1940, every vestige of the international liberal order had disappeared, the product of the necessary adoption of measures designed to hold off the ravages of the self-regulating market; that is, ‘market despotism’. It was the conflict between the market and the elementary requirements of an organized social life that made some form of collectivism or planning inevitable. The liberal market order was, contra Hayek, not ‘spontaneous’ but a planned development, and its demise was the product of the market order itself. A market order could just as well produce the freedom to exploit as the freedom to associate. The grave danger, in Polanyi’s view, was that liberal utopianism might return in the idea of freedom as nothing more than the advocacy of free enterprise, in which planning is ‘the denial of freedom’, and the justice and liberty offered by regulation or control just ‘a camouflage of slavery’. Liberalism on this account will always degenerate, ultimately compromised by an authoritarianism that will be invoked as a counterweight to the threat of mass democracy. Modern capitalism, he said, contained the famous ‘double-movement’ in which
markets were serially and coextensively disem- ed from, and re-embedded in, social institutions and relations. In particular, the possibility of a counter-hegemony to the self-regulating market resided in the resistance to (and reaction against) the commodification of the three fictitious commodities – land, labour and money – that represented the spontaneous defence of society.

Marx’s account identifies a fundamental contradiction at the heart of capitalism – a contradiction between two great classes (workers and owners of capital) that is fundamentally an exploitative relation shaped by the appropriation of surplus. Unlike FEUDALISM, in which surplus appropriation is transparent (in the forms of taxes and levies made by landowners and lords, backed by the power of the church and Crown), surplus value is obscured in the capitalist LABOUR PROCESS. Marx (1967) argues that labour is the only source of value and value is the embodiment of a quantum of socially necessary labour. It is the difference between the sale of a worker’s labour power and the amount of labour necessary to reproduce it that is the source of surplus value. The means by which capital extracts this surplus value under capitalism – through the working day, labour intensification and enhancing labour productivity – coupled to the changing relations between variable and constant capital determine, in Marx’s view, the extent, degree and forms of exploitation. In the first volume of Capital, Marx identifies the origins of surplus value in the organization of production (the social relations of production so-called). In volume II, Marx explains how exploitation affects the circulation of capital, and in volume III he traces the division of the total product of exploitation among its beneficiaries and the contradiction so created. In Marxist theory two kinds of material interests – interests securing material welfare and interests enhancing economic power – are linked through exploitation (exploiters simultaneously obtain greater economic welfare and greater economic power by retaining control over the social allocation of surplus through investments). Members of a class, in short, hold a common set of interests and therefore have common interests with respect to the process of exploitation (see also MARXISM).

In the wake of Marx’s work, the central debates over capitalist exploitation have turned on (i) whether the labour theory of value is a necessary condition for any truth claim about exploitation, (ii) whether exploitation can be made congruent with the complex forms of class differentiation associated with modern industrial society, and (iii) whether there are non-Marxist accounts of exploitation. In NEOCLASSICAL ECONOMICS, for example, exploitation under capitalism is seen as ‘the failure to pay labour its marginal product’ (Brewer, 1987, p. 86). Exploitation in this view is micro-level and organizational. That is to say, using micro-economic theory exploitation is a type of market failure due to the existence of monopoly or monopsony. In more developed versions of this organizational view, exploitation can be rooted in extra-market forces; for example, free-riding or asymmetric information (the so-called principal–agent problem). A more structural account of exploitation from a liberal vantage point would be the ideas of Henry George or John Maynard Keynes, for whom land owners or rentier classes (non-working owners of financial wealth) produce not exploitation in the Marxist sense, but exploitation as waste and inefficiency due to ‘special interests’.

In the Marxian tradition, there has been in general an abandonment of the labour theory of value – away from the view of Elster (1986) that ‘workers are exploited if they work longer hours than the number of hours employed in the goods they consume’ (1986, p. 121) – towards John Roemer’s notion that a group is exploited if it has ‘some conditionally feasible alternative under which its members would be better off’ (Roemer, 1986a, p. 136). Perhaps the central figure in developing these arguments is Erik Olin Wright (1985), who sought to account for the contradictory class location of the ‘middle classes’ (in that they are simultaneously exploiters and exploited). Building on the work of Roemer, Wright distinguishes four types of assets, the unequal control or ownership of which constitute four distinct forms of exploitation under capitalism: labour power assets (feudal exploitation), capital assets (capitalist exploitation), organization assets (statist exploitation) and skill assets (socialist exploitation). While pure modes of production can be identified with single forms of exploitation, ‘actually existing capitalism’ consists of all four, opening up the possibility of the simultaneous operation of exploiter/exploitee relations (e.g. managers are capitalistically exploited but are organizational exploiters).

A long line of Marx-inspired theorizing has attempted to grasp the relations between (European or transatlantic) capitalism, EMPIRE and the non-capitalist (or developing) world. This is the heart of theories of IMPERIALISM
(Lenin, 1916), whether as the coercive extraction of surplus through colonial states (Fanon, 1967 [1961]), through unequal exchange (Arrighi and Pearce, 1972), or through the imperial operation of transnational banks and multilateral development institutions (the World Bank and the International Monetary Fund). The so-called ‘anti-globalization’ movement (especially focusing on institutions such as the World Trade Organization) and the ‘sweatshop movements’ (focusing on transnational firms such as Nike) are contemporary exemplars of a politics of exploitation linking advanced capitalist state and transnational corporations with the poverty and immiseration of the global south against a backdrop of neo-liberalism and free trade (Harvey, 2005; Starr, 2005).

It is axiomatic that there has been enormous controversy over the operations, the merits and the costs of the capitalist system since the nineteenth century. Much ink has also been spilled attempting to provide periodization or classifications of actually existing capitalisms and the origins of capitalism in the transformation from feudalism. The pluralization of the word capitalism – capitalisms – highlights enormous geographical, temporal, institutional and cultural diversity of what is now a global and integral form of political economy. The originary question hinges in large measure on engaging with Marx’s account of primitive accumulations and the British enclosures, and the extent to which the feudal system was transformed by the corrosive effects of the markets and/or urban-based merchants, by demography or by internal contradictions within the feudal system (reflections in class and other struggles between tenants, lords, the Church and merchants). The periodization of capitalism turns on similar theoretical tensions: Was ‘early’ capitalism characterized by expansionary trade and the dominance of merchants’ capital? Was this early mercantile capitalism actually in the business of inventing new systems of capitalism production (e.g. the plantation)? What was – or is – the relation between forms of unfree labour (some of which still exist, although not as organized mass slavery) and the development of industrial capitalism? To what extent were the accumulations associated with differing phases of the development of the world system – slavery, informal empire, and the first age of empire – integral to the rise of industrial capitalism in Britain or elsewhere in Europe? These questions have produced a vast body of scholarship and theorizing. What can be said, with some trepidation, is that while the trajectories of capitalism in Europe and elsewhere have some substantive diversity, there is some agreement that the rise of industrial manufacture in Britain in the eighteenth century, the growing concentration of capitals (and the linking of industrial and bank capital) at the end of the nineteenth century, the institutionalization of a sort of Keynesian capitalism in the wake of the First World War, and the genesis of a resurrected ‘liberal capitalism’ (dubbed neo-liberalism, echoing the late nineteenth century) as a force driving the post-1945 globalization of transnational capitalism are key moments – or watersheds – in the long march of modern capitalism. The national and local forms in which the great arch of capitalist development has been institutionalized – sometimes theorized as systems of regulation or social accumulation (see Regulation Theory), sometimes as national capitalisms, sometimes as models or cultures of capitalism – has generated a very substantial and sophisticated body of work over the past three to four decades, including an important dialogue over the differences between the first and ‘late’ developers (e.g. the so-called Asian tigers).

Geographers, particularly since the 1970s, have been especially concerned to address the relations between space, environment and the reproduction of the capitalist system. The most elaborated account in the English language is the body of work of David Harvey (1999 [1982]) – but one might easily point to an equally expansive and synoptic account in the work of Henri Lefebvre (2003 [1970]). Harvey’s work began as a critical account of the city in the advanced capitalist states, but quickly developed into a magisterial re-reading of capital in which the friction of space – and what he termed the ‘spatial fix’ – provided a key theoretical ground on which to understand the circuits of capital (see figure) and the built environment, the changing geography of capitalist accumulation and the environmental costs of – and, more recently, the relations between American empire and primitive accumulation (what he calls accumulation by dispossession). Other geographers have naturally contributed to the space–nature–capitalism triumvirate: Doreen Massey on spatial divisions of labour, Neil Smith on uneven development, Richard Walker on regional and agrarian capitalism, Ash Amin on industrial districts, Gillian Hart on trajectories of capitalism, Stuart Corbridge and Richard Peet on neo-liberalism and development, and so on.
Since the 1990s, the spectacular rise of neo-liberalism as a specific form of capitalist development and its relation to questions of empire, development and environment has drawn much critical attention. David Harvey’s *A brief history of neoliberalism* (2005) attempts to map the dismantling of the social democratic world, with a special focus on the British form of national Keynesianism, inflected by the command economy of the Second World War, but whose roots lay earlier in the response of the managers of North Atlantic capitalism to the Depression, and which came in the form of welfare safety nets, income redistribution, domestic industry protection, state-financed public works and capital controls – ‘embedded liberalism’ of the Polanyian sort.

The rise of neo-liberal capitalism was in a sense the victory of Friedrich von Hayek’s *The road to serfdom*. It was Margaret Thatcher, after all, who pronounced, at a Tory Cabinet meeting, ‘This is what we believe’, slamming a copy of Hayek’s *The constitution of liberty* onto the table at 10 Downing Street. His critique of collectivism – that it destroys morals, personal freedom and responsibility, impedes the production of wealth, and sooner or later leads to totalitarianism – is the ur-text for market utopians. Collectivism was, Hayek said, constructivist rather than evolutionary, organized not spontaneous, an economy rather than a ‘catallaxy’, coerced and concrete rather than free and abstract.

As Antonio Gramsci might have put it, there has been a Hayekian ‘passive revolution’ from above, in which we have witnessed what Perry Anderson has dubbed a ‘neoliberal grand slam’ (2000c). The vision of the Right has no equivalent on the Left; it rules undivided across the globe and is the most successful ideology in world history.

The process by which neo-liberal capitalist hegemony was established, and its relation to forms and modes and sites of resistance, remains a story for which, even with Harvey’s synoptic survey at hand, we still have no full genealogy. Neo-liberalism was a class reaction to the crisis of the 1970s (Harvey talks of a ‘restoration of class power’); on that much, Milton Friedman and David Harvey are agreed. But we are still left with many paradoxes and puzzles. Why, for example, did the LSE and Chicago – once the respective centres of Fabianism and a certain version of (American) liberalism under Robert Hutchins – become the forcing houses of neo-liberalism? What were the facilitating conditions that fostered the arrival of the maverick Ronald Coase in Chicago, marking a neo-liberal turning point? How did the World Bank – a bastion
of post-war development economics and, it must be said, of statism – become the voice of laissez faire? How can we grasp the fact that ‘shock therapy’ in eastern Europe was more the product of the enthusiastic Hungarian reformers than of the more reticent American neo-liberal apparatchiks? It is sometimes noted that the 1991 World Development Report (shaped by former US Secretary of the Treasury Lawrence Summers) marked a neo-liberal watershed in its refiguring of the role of the state. But it was AFRICA (not LATIN AMERICA or eastern Europe) that proved to be the first testing ground of neo-liberalism’s assault on the over-extended public sector, on physical capital formation and on the proliferation of market distortions by government. There is much that remains unclear in the rise of neo-liberal hegemony as a particular force of capital accumulation.

As Polanyi might have anticipated, three decades of radical neo-liberalism culminated in the autumn of 2008 with a spectacular and massive implosion of the US financial sector, turning quickly into a deeper and systemic crisis of capitalism itself. The catastrophic collapse of US investment banks – which ramified globally producing de facto bank nationalizations in much of western Europe – was triggered by a classic housing bubble. During the 1990s, however, this bubble was, unlike the past, driven by new and dubious financial and mortgage instruments, and by the utter failure of the financial regulatory institutions (the credit rating agencies and the Securities and Exchange Commission in particular). By late 2008, in spite of a massive $700 billion bailout by the US Treasury, credit and the banking sector remained in effect frozen and the prospect of a massive global recession loomed. The great experiment in free market utopianism - the so-called ‘neo-liberal grand slam’ - had put Keynesianism back on the political agenda. In the US and much of Europe, a Polyanian counter-revolution - in the US there is talk of a new New Deal – is now in the offing.

**capture–recapture methods** A SAMPLING technique that was developed in ECOLOGY to estimate population size and vital rates (including survival, movement and growth). A search is made in a defined area and identified ANIMALS are captured and marked or recorded in some way. Visits are made on subsequent occasions and the proportion of unmarked animals is recorded; this allows, given assumptions, the estimation of the total population. Model-based approaches (Cormack, 1989) have been developed that use CATEGORICAL DATA ANALYSIS to provide confidence intervals for the estimates. With human populations, the method uses the extent to which the same individuals are to be found in different data sources; thus Hickman, Higgins, Hope et al. (2004) estimated the total number of drug users by using five data sources – community recruited survey, specialist drug treatment, arrest referral, syringe exchange, and accident and emergency.
Just as prisons restrict the mobility of individuals inside their walls, they are central to the regulation of movement of people across boundaries, particularly given concerns about security in this age of panic about terrorism. The most obvious example here is the USA, which operates a separate set of prisons for those accused of immigration violations. These detention centres are run by the executive branch of the federal government, and thus lie largely outside judicial review. Detentions can be indefinite, and detainees left bereft of legal representation. Such detention centres reportedly house many suspected of plotting terrorist acts (Dow, 2004). Beyond its own territory, the USA operates camps and so-called ‘black sites’, part of a global war prison where practices of torture and otherwise inhumane detention take place outside the constraints of international law (Gregory, 2007).

Incarceration thus becomes implicated in wider processes of citizenship, migration and national security. Borders become heavily policed (Nevins, 2002) and those arrested crossing illicitly are subject to indefinite detention and possible deportation. Those who do manage to cross illegally come to inhabit ‘spaces of non-existence’ (Coutin, 2003), invisible to legal and other authorities, and thus deprived of the benefits of formal recognition. Full citizenship, however, hardly leaves one outside of places that are heavily monitored and tightly controlled: in a world of increasing surveillance and security consciousness, the scope of carceral geographies promises to widen.

**Carrying capacity** A concept developed mainly in population biology and ecology that commonly refers to the maximum number of a given species that a given environment can support indefinitely. Developed with respect to animal populations that grow quickly and then crash precipitously when they exceed their environment’s carrying capacity, it has been widely but controversially applied to human–environment relations (e.g. efforts to quantify the maximum number of park visitors compatible with conservation, or the maximum human population that the Earth can support). Such applications frequently neglect more relevant questions regarding the complex social dynamics of resource use, particularly issues of distributive justice and technological change.

**Cartesianism** In order to provide a firm and permanent structure for the sciences, the philosopher René Descartes (1596–1650) outlined a method of enquiry based on certain and indubitable knowledge. The kind of knowing learned from hearsay, teachers and parents was seen to be suspect, marked by the uncertainties of opinion (doxa). Only knowledge derived from reason and method (episteme) provided adequate foundations for scientific knowledge, and clear and explicit criteria for demarcating scientific from non-scientific claims (Bernstein, 1983, p. 23). For Logical empiricism and logical positivism, such methods were seen to offer the possibility of developing a universal science that would share common foundations and principles. Such Cartesian science was to be disinterested, objective, value-free, universal and abstract, and it was based on a firm belief that science represented nature in a direct manner, serving – as Rorty (1979) suggested – as ‘the mirror of nature’ (cf. mimesis). Bernstein (1983) referred to this history of scientific efforts to found basic statements in direct observation of an external reality as the Cartesian anxiety, a term that Gregory (1994, pp. 71–3) extended to the cartographical and geographical project (see cartographic reason).

In the 1960s, the growing power and reach of universal science, hypothetico-deductive methodologies and mathematical abstraction in the natural and social sciences led to a series of disciplinary methodenstreiten (‘struggles over method’). The Positivist dispute in German sociology (see Adorno, 1976) was particularly influential in this struggle, bringing together the views of a broad group of philosophers of science, including Thomas Kuhn, Karl Popper, Imre Lakatos, Paul Feyerabend, Jürgen Habermas and Theodor Adorno, on the limits of disinterested, value-free and universalist understandings of science. In Human geography, a critique of Cartesianism, and the clearest reflection of this broader methodenstreit, was provided by Gregory (1978a), who argued against positivism and spatial analytic claims to a privileged form of knowledge production. Instead, geographical science was never disinterested or innocent, but always a social activity framed by determinate interests. Habermas (1987a [1968]) had argued that knowledge claims must be understood in terms of such interests (see also phenomenology),
and Gregory elaborated these claims for geography. In the place of a single privileged scientific method, Gregory outlined a plurality of scientific epistemologies, each one determined by the specific knowledge-constitutive interests that give rise to them (he identified three: technical, interpretative and emancipatory). Corresponding to each knowledge-constitutive interest was a particular form of science: empirical, HERMENEUTIC and critical (see CRITICAL THEORY). Since then, it has become commonplace to treat geographical enquiry, like all forms of intellectual enquiry, as an irredeemably social practice, although this has been understood in ways that often differ significantly from Habermas’ original theses, and the rise of a CRITICAL HUMAN GEOGRAPHY has been accompanied by a series of searching enquiries into the effects produced through REPRESENTATION and other modes of apprehending the world (see NON-REPRESENTATIONAL THEORY).

**cartogram**  A customized MAP PROJECTION that adjusts area or distance to reveal patterns not apparent on a conventional base MAP. For area cartograms this adjustment might be specific, as when the areas of countries or provinces are made proportional to their populations (Dorling, 1993), or expedient, as when small places such as Luxembourg or Rhode Island are rendered sufficiently large so that their symbols on a CHOROPLETH map are readily visible. Similarly, distance cartograms might adjust distances to reflect TRANSPORT COST relative to a particular place (Mommonier, 1993, pp. 198–200) or rearrange transport routes to promote clarity, as on the widely imitated London Underground map.

**Suggested reading**  Gastner and Newman (2004).

**cartographic reason**  The belief that cartographic and geographical representations are direct representations of an external and independent world or, as the philosopher Richard Rorty (1979) put it more generally, they are the ‘mirror of nature’ (see also CARTESIANISM; OBJECTIVITY). In this view, the task of CARTOGRAPHY and GEOGRAPHY is to represent the external world faithfully, and the criterion for success and hence ‘truth’ is the degree to which this correspondence is achieved. This view of REPRESENTATION depends upon a cartographic theory of correspondence in which, to take the METAPHOR at its most literal, information about the world is accurately transmitted (primary sense data) through a medium (the MAP) to a receiver (the map reader) (for a critical reading, see Pickles, 1992). The accuracy of the transmission of the information from the real world to the reader is a measure of the accuracy and hence effectiveness of the mapping process. This representational notion of SCIENCE presumed that the world was external and independent of the observer and that the nominally scientific observer could describe the world in ways that corresponded directly to the reality of the world. Such foundational and objectivist epistemologies have variously been referred to as observer epistemologies or, in an acknowledgement of the effects that they produce, the ‘god-trick’ (Haraway, 1991d) and the ‘Cartesian Anxiety’ (Bernstein, 1983). It was this latter term that Gregory (1994) adapted as the cartographic anxiety to characterize a particular mode of GEOGRAPHICAL IMAGINATION.

Some commentators have associated such critiques of cartographic reason with the influence of POSTMODERNISM on HUMAN GEOGRAPHY, but some of the most telling interventions have been inspired by MODERNISM and its sustained interrogation of representational practices. Thus for Olsson (2007, p. 4), the thought of such a tabula rasa, a pristine world uncontaminated by the act of knowing, is literally unimaginable, and theories of human knowledge that presume such a beginning point or possibility are deeply flawed. Instead, for Olsson, the drawing and interpreting of a line is the cartographic act exemplified. It is always an act that creates meaning; every drawing of a line is the creation of a distinction, the delimiting of an identity, and the creation of a BOUNDARY. As Pickles (2004) shows, by inscribing lines, creating distinctions, and drawing borders, cartography and, by extension, geography, can be seen as a part of a diverse array of cultural practices and politics that are constantly producing and reproducing worlds (see also Farinelli, Olsson and Reichert, 1994).

**cartography**  (1) The design and production of MAPS by individuals or organizations; (2) the scientific study of the technology of mapmaking and the effectiveness of maps as communication devices; and (3) the scholarly examination of the societal role and impact of maps. The term’s association with mapmaking reflects lexical roots in carte (French for map) and graphie (Greek for writing). Although mapmaking is an ancient art, cartography is a nineteenth-century word, introduced in 1839 by Portuguese
scholar Manuel Francisco de Barros e Sousa, Viscount of Santarém, who used it to describe map study in the same way that historiography refers to the history of historical writing (Wolter, 1975). Although Santarém referred only to early maps, the word evolved to include contemporary maps and mapping as well as ancient artefacts (Harley, 1987, p. 12).

As a synonym for mapmaking, cartography is often construed to include the collection of geographical information through systematic surveys, formal or otherwise, of the physical landscape or its human occupants. In an institutional context, cartography might refer narrowly to the production of artwork for printed maps (also called ‘map finishing’) or more broadly to the overall mission of a commercial firm such as Rand McNally or a government agency such as the Ordnance Survey. Although individuals working as freelance mapmakers or non-faculty staff members of an academic geography department are still content to call their work cartography and themselves cartographers, the term’s other institutional connotations declined markedly in the final years of the twentieth century, when new technologies (see DIGITAL CARTOGRAPHY; GEOGRAPHIC INFORMATION SYSTEMS; REMOTE SENSING) and new business models undermined the paper map’s traditional role in storing and distributing geographical information, and organizations at different levels replaced ‘cartography’ as a descriptor with more fashionable labels based on ‘geospatial’ or ‘geographical information’.

As a scientific endeavour focused on the increasing efficiency in mapmaking, improving the reliability of map communication, or enhancing the understanding of cognitive processes involved in decoding and using maps, cartography remains an active if somewhat retrenched sub-discipline of GEOGRAPHY. Moreover, its boundary with GEOGRAPHIC INFORMATION SCIENCE is blurred insofar as many (perhaps most) academics trained as cartographers not only understand the power and limitations of geospatial technology but know how to use GI software. Similarly, many (but probably not most) academics trained as GI scientists not only appreciate the map as an interface and display device but also recognize the inadequacy of current GI software as a design tool. Labelling became especially important in the 1990s, as older faculty retooled and academic departments converted course titles and job descriptions from cartography to GIS. The American Cartographer became Cartography and Geographic Information Systems in 1990, only to reposition itself as Cartography and Geographic Information Science nine years later. Despite this blatant but apparently successful attempt to retain market share through re-branding, the journal remains committed to improving the practice and understanding of map communication, albeit with a clear emphasis on electronic and digital cartography.

Map-design research has theoretical, technical and more ostensibly scientific–empirical themes, with the latter often relying on subject-testing to improve pedagogical approaches to map reading, enhance understanding of how the human eye-brain system processes map information (MacEachren, 1995), and evaluate the effectiveness of competing solutions to design problems (Montello, 2002). In the latter three empirical realms, academic cartographers constitute a numerical and philosophical majority only in design-related cartographic research, which also includes work on dynamic and interactive maps, multi-sensory cartographic interfaces (see VISUALIZATION), and tactile maps for persons with impaired vision (Perkins, 2002). Not surprisingly, educational psychologists and cognitive psychologists dominate explorations of map-reading and cognitive mapping, respectively.

Arthur Robinson’s The look of maps (1952) was the seminal work in empirical map–design research, a topic taken up in various guises by Robinson’s graduate students and their intellectual offspring. Robinson held that effective map design required an appreciation of the design’s impact on map viewers, whose ability to decode cartographic symbols was understandably impaired if they could not read labels or detect crucial differences in line thickness, greytones or colour. Aligned philosophically with the LOGICAL POSITIVISM of the QUANTITATIVE REVOLUTION, map-design researchers uncritically adopted psychophysics, a PARADIGM in experimental psychology that treats the magnitude of a response as a power function of the magnitude of the activating stimulus (Montello, 2002, pp. 288–9). A succession of empirical studies attempted to ‘rescale’ graduated circles, line weights and greytones to the perceptual prowess of a hypothetical average map reader, an attractive concept undermined by variations in cognitive style, training and prior knowledge as well as by the unavoidable distractions of nearby symbols in the ‘map environment’. Although less ambitious studies of ‘just noticeable differences’ among lines, greytones and colours provided reliable guidance for mapmakers,
map-design research lost momentum in the 1980s, when the shortcomings of psychophysical rescaling became apparent. Despite this disappointment, subject-testing remains a useful strategy for evaluating solutions to problems in map design, and empirical studies experienced a revival in the 1990s, when the computer proved a valuable tool for testing subjects and qualitative methods such as focus-group interviews offered further insights (Suchan and Brewer, 2000).

Computers fostered numerous technical advances as well, including automated strategies for placing labels in non-overlapping locations, generalizing linear features, classifying data for choropleth maps, interpolating isolines, generating oblique views of three-dimensional surfaces, and creating visually effective animated and interactive maps (Monmonier and McMaster, 2004). Although the computer was ostensibly an instrument of mapmaking, these techniques clearly functioned as tools for map design insofar as the map author could readily experiment with thresholds, parameters and methods of symbolization. Although the limitations of psychophysics were readily apparent in the 1980s, interactive maps that the user could query with a cursor further undermined the need to improve value estimation by rescaling map symbols.

Two other theories prominent in cartography in the 1970s were the communication model and a conceptual framework called visual variables. Derived from feedback-loop models in information theory, the cartographic communication model in its simplest form treated the map as a channel connecting a map author (source) with a perceiver (destination). A more elaborate version treated the map author as a filter that helped form the percipient’s view of the world and added a reverse flow (feedback), which encouraged a modification of the map’s design or content to promote a more accurate transmission of the map author’s intended message. Particularly noteworthy was a comparatively sophisticated modification by Antonín Koláčný (1969), whose model described the cartographer’s reality and the map user’s reality as overlapping but not completely coincident subsets of a larger reality. Although the communication paradigm received considerable attention in the academic press and no doubt heightened awareness of communication among academic cartographers, the notion that all maps, or even most maps, contain discernible biases made the label ‘social construction’ particularly appropriate (Vujakovic, 1999; Schulten, 2005).

Harley challenged scholars to question the motives of mapmakers by deconstructing contemporary as well as historic maps (cf. deconstruction). Although the studies that followed sometimes bordered on mild paranoia in their disdain for evidence of intent or impact – Pickles’ (2004, pp. 60–71) critique of exaggerated claims for the ‘power of maps’ includes some good examples – other scholars combined an insightful examination of the map author’s mindset with a careful appraisal of the institutional context in which maps were produced. For example, Herb (1997) tied the development of strident late-1930s German
propaganda maps, which probably convinced few people who were not already Nazi sympathizers, to a post-First World War collaboration between scholars and activist politicians eager for a ‘Greater Germany’. Similarly, Cosgrove and della Dora (2005) offer a perceptive interpretation of the vivid pictorial Second World War maps of *Los Angeles Times* cartographer Charles Owens, a self-trained newspaper artist fascinated with aviation, cinema and photo-journalism. Cloud (2002), whose work is similarly grounded in archives and interviews, studied the ‘military–industrial–academic complex’ during the Cold War and provides numerous insights on the intelligence community’s contributions to private-sector GIS and remote sensing, including the use of classified satellite imagery to update domestic TOPOGRAPHIC MAPS and the paradox of conceptual details of top-secret research and development efforts ‘hidden in plain sight’ in readily available cartographic and photographmetric journals.

Research on the societal impacts of mapping is also concerned with public access to geographical information, including the role of government and other institutions in producing and distributing maps, influencing their content, and restraining or promoting their use. In this context, the map becomes not only an artefact or tool, but also a piece of intellectual property or an opportunity for international collaboration (Rhind, 2000). Moreover, growing use of the Internet as a medium for delivering and integrating geographical information has not only altered the appearance and usability of maps but substantially altered relationships between public and private sectors as well as between map author and map viewer (Taylor, 2006a). The increasingly eclectic nature of maps and mapping promises to make map study a fascinating and challenging geographical endeavour, whatever one calls it.

**Cartography, history of** The study of the processes whereby people in all cultures and in all periods have variously made and used MAPS to comprehend, organize and act in space and place, together with their motives for and effects of doing so. A primary element of HUMAN GEOGRAPHY and the HISTORY OF GEOGRAPHY, the history of CARTOGRAPHY is also widely recognized across the HUMANITIES and social sciences as an intellectually vibrant and exemplary interdisciplinary field of study that draws on and makes significant contributions to many historical fields. Note that ‘historical cartography’ *per se* is the practice of representing past distributions or events in maps; as such, it constitutes a particular topic for historians of cartography (Skelton, 1972).

Librarians, professors, lawyers and lay scholars (notably collectors and their dealers) have studied maps as historical phenomena since the 1700s. Traditionally, such studies have elucidated the content of old maps in order to generate locational and morphological data for use by other historians, notably those of geography, exploration and COLONIALISM, but also historical geographers, geomorphologists, lawyers, archaeologists and students of cities and landscapes. Even so, there was little disciplinary identity for such ‘map history’ before the twentieth century: map historians were few in number, widely dispersed and they were constrained within national schools by differential physical and linguistic access to primary sources. The viscount de Santarém’s 1839 neologism of ‘cartography’, to mean the study of old maps, accordingly could not take root; it was instead quickly appropriated by professional mapmakers. A more coherent scholarly community coalesced around *Imago Mundi*, founded in 1935 by Leo Bagrow; this is still the leading journal in the field and has since 1967 given rise to biennial international conferences (Skelton, 1972; Harley, 1986, 1987; Edney, 2005a).

The successful promotion after 1945 of cartography as an academic subject entailed the expansion and consolidation of a previously minor, sporadic and internalist history of cartographic techniques. The new concern for such a ‘history of cartography’ was truly innovative in that it focused on map form rather than on map content, and on archival and contextual research rather than on cartobibliography and map analysis. It generated significant studies, for example of the histories of map printing and thematic mapping. From this perspective, academic cartography provided historians of cartography – however briefly – with both an intellectual framework (Woodward, 1974) and an institutional home (Harley and Woodward, 1989; Edney, 2005b).

Both ‘map history’ and the ‘history of cartography’ were thoroughly intertwined with the modern ideology of cartography. Indeed, that ideology has in large part depended upon...
cartographic history for legitimation: the historians’ narratives of past cartographic progress, whether in content or in form, validated the modern convictions that maps are unproblematic replications of geographical data (see CARTOGRAPHIC REASON) and that cartography is an inherently moral practice aimed at improving the human condition. Map history has thus served as a surrogate for the triumphs of modern Western SCIENCE and CIVILIZATION generally. These EMPIRICIST and POSITIVIST ideals were further perpetuated by the historical narratives constructed in order to justify an academic status for cartography (Edney, 2005b), and they further underpin a rapidly growing popular literature that allies the powerful myth of cartographic progress to the equally powerful myth of the lone scientific genius.

Paradoxically, the ‘history of cartography’ ended up establishing the broader intellectual potential of map studies and led to the proliferation of a ‘history of cartography’ that has taken map studies far beyond the confines of academic cartography and geography (Edney, 2005a,b). Several factors contributed to the shift: attention to the larger historical record revealed many more cartographic activities than were encompassed by the established canon; detailed archival studies increasingly suggested that maps must be considered as humanistic as well as technological/scientific documents; academic cartography’s adherence to models of communication made some historians aware of the need to study how maps were used as well as made; and academic cartography’s claims to intellectual autonomy were matched by arguments that the history of cartography should no longer be subservient to other fields (esp. Blakemore and Harley, 1980). A triumphal, empiricist history of cartographic progress was increasingly recognized as intellectually bankrupt. In 1977, Denis Wood could accordingly present a structuralist reinterpretation of the history of cartography as part of a larger critique of academic cartography (see STRUCTURALISM). For Wood, the history of cartography replicated the development of spatial cognition in the individual; he has subsequently clung to this argument, even as he has made truly significant distinctions between the necessarily social processes of ‘map making’ and individual processes of cognitive ‘mapping’ (Wood and Fels, 1992).

By the late 1970s, Brian Harley and David Woodward had set out to create a new, autonomous discipline of the history of cartography by unifying the widely dispersed literature within a multi-volume History of cartography. Even with only three of six volumes published to date, the series has already proven enormously influential in promoting the Catholic and humanistic study of cartographic history. The extensive consideration given to non-Western and pre-modern cartographies has loosened the West’s putative stranglehold on ‘proper’ cartography and has seriously undermined the conviction that maps must be geometrically consistent, measured and graphic in nature. The series has demonstrated unequivocally not only that the history of cartography is a valid field of study in its own right but also that it cannot hope to make significant contributions as long as it adheres to modern cartographic IDEOLOGY (Harley and Woodward, 1987–continues; see Woodward, Delano Smith and Yee, 2001, esp. pp. 23–9; Edney, 2005b).

Harley also set out to create a new intellectual identity for the field. His initial foray, with Michael Blakemore, drew on the art-historical principles of ICONOGRAPHY to demonstrate the manner in which maps necessarily bear cultural and social significance in addition to factual and locational data (Blakemore and Harley, 1980). Subsequently, and largely influenced by the work of philosopher–historian Michel Foucault, Harley advanced a series of essays on the inherently political nature of all maps (Harley, 2001b). Harley’s essays from the 1980s were crucial in that they crystallized the intellectual concerns with modern cartographic ideology already expressed by many scholars across several disciplines, waved the flag for more critical map studies and served as prominent vehicles for human geography’s adoption of approaches informed by POST-STRUCTURALISM. His essays were nonetheless incomplete. Harley succeeded brilliantly in exposing modern cartographic ideology by wrenching off its mask of OBJECTIVITY, but he was ultimately unable to theorize a new, critical PARADIGM (Edney, 2005a).

Parallel to, drawing on, and at the same time motivating Harley’s theoretical exposés were studies by scholars in other fields who, unburdened with any disciplinary baggage, recognized (or simply ignored) the traditional shortcomings of map history. These scholars included sociologists and political scientists as well as historians (e.g. Winichakul, 1994; see GEO-BODY), but most were literary scholars who began to consider maps as simply one more strategy of REPRESENTATION within
have been habitually circumscribed; and the patterns of map consumption, particularly in terms of ‘print culture’, in order to delimit the social limits of specific discourses in which maps figured and to explore the interconnections between maps and other representational strategies (Edney, 2006). All told, critical histories of cartography have promoted cartographic studies into a significant component of research in the humanities and social sciences.

Yet there is need for caution. Modern cartographic ideologies continue to infect much supposedly critical work. Whereas the very concept of ‘map’ is itself culturally determined (Jacob, 2006) and the making of maps is distributed across several modes that are not necessarily connected (Edney, 1993), there remains a tendency to treat ‘map’ as a self-evident category that is constant across cultures and to understand ‘cartography’ as a singular endeavour; discourse analysis based on such misconceptions inevitably fails. Again, a reading of Harley’s essays without consideration of the larger stream of post-structuralist thought has led many scholars to continue to understand map meaning as being determined solely by mapmakers working for socially privileged patrons: in this arrangement, a map’s meaning is bifurcated into a culturally insensitive ‘factual’ layer and a ‘symbolic’ layer that is manipulated by the map’s maker to achieve some kind of effect on its readers. Such an approach denies the agency of the map-reader and so fails to realize fully the conventions of cartographic discourses and their constructions of spatial meaning. In this respect, the transition to a coherent critical paradigm of cartographic history remains incomplete.

Furthermore, critical theory does not provide by itself a sufficient basis for the history of cartography. Rigorous analysis of a spatial discourse requires a clear grasp of the forms of maps involved in the discourse, of the social and geographical patterns of that discourse, and of the relevant political and economic contexts. That is, critical studies must be competently grounded in an empirical archive. Much scope accordingly remains for cartobibliographies to elucidate the patterns of map availability (e.g. Krogt, 1997– ), although the carto-bibliographies need to be carefully designed and implemented.

The history of cartography might thus at present be described as a three-layer intellectual palimpsest. Traditional approaches have not been completely erased: they are still quite...
CASE STUDY

visible, especially within popular writing, and it is hard to escape the restrictions of the progressivist canon and its underlying presumptions. Academic cartographers continue to pursue an internalist history, now reconfiguring it to account for the new directions being taken by digital technologies (Slocum, McMaster, Kessler and Howard, 2008).

Intelliectually, the future clearly lies with the new catholic and critical history of cartography; its challenge is to turn the older strains of cartographic historiography to its own ends, remaining empirically strong but consolidating a coherent and interdisciplinary intellectual presence.

case study The case study epitomizes a process or complex set of processes in context, thereby demonstrating how theoretical tools can be applied to the social world. The idea of the case study emerged in the 1930s through attempts to make the human sciences a parallel enterprise to the biophysical sciences, specifically in trying to see instantiations of sociological theory in the manner of medical case histories. Urban sociologists, mainly from the CHICAGO SCHOOL, saw the case study as the ideal method to produce hypotheses. For instance, Whyte’s Street corner society (1943) is a classic case study of life, gangs, work and politics in a working-class Italian neighbourhood in Boston. By the late 1960s, the sociological approach of Grounded Theory advocated building theory through case studies, as a kind of stylized empiricism.

However, sociological thought has paid much longer attention to what Max Weber called ‘configurations’ of seemingly objective regularities or hypothetical laws, which only become intelligible in specific, concrete situations (Weber, 1949). Considered as a Weberian configuration, the case study separates contingent from necessary causes and context from structuring process, to show how both elements come together in concrete conjunctures. The Weberian approach, it would seem, provides more durable analytical tools than some of its successors in urban sociology.

Contemporary critiques from scholars such as Dipesh Chakrabarty of the Subaltern Studies Collective question the underlying presumption to objectify lived histories in cases that conceal the translation of local into expert knowledge (see SUBALTERN STUDIES). This insight would suggest that as long as disciplinary authority is itself part of the object of analysis, case studies can remain efficacious in engaging concrete interactions between expert knowledges and forms of belonging. Such an interactive conception of the case study is particularly useful from the perspective of a HUMAN GEOGRAPHY that strives to show how broader processes work through specific constellations of social space. Through Massey’s notion of an extroverted SENSE OF PLACE (Massey, 1994b), one can conceive of ‘case geographies’ as intersections of dynamic, mobile, constructed and contested spatial processes. Another constructive critique of case studies emerges from Mary Poovey’s (1998) interrogation of the boundaries between descriptive and interpretive evidence in the making of the modern fact. Poovey’s analysis contrasts the kind of evidence that makes for case studies against the seemingly non-evaluative numerical and statistical indices that surround such objects of evidence. The useful insight in thinking of particular geographical cases is to ask what work the division of NOMOTHETIC and IDIOGRAPHIC forms of knowledge accomplishes in maintaining or undermining the coherence of actual cases.

caste An endogamous social hierarchy of enduring political significance, believed to have emerged some 3500 years ago around highly questionable categories of Aryans and non-Aryans in the Indian subcontinent. The former – comprising brahman, kshatriya and vaishya – emerged as dominant occupational castes of so-called dvija (twice-born). The shudra caste(s) – regarded as non-Aryan and ‘mixed’ – were occupationally marginalized and racialized, as was also the case later with the ‘outcastes’ (Dalit), whose touch was deemed polluting (Thapar, 1966). This order was challenged from the sixth century BCE, but all major religions in India came to bear the social imprint of caste. Brahman social dominance was bolstered by a British neo-Brahmanical ruling IDEOLOGY, and provoked a backlash (Bose and Jalal, 1997). Significantly, leaders such as Lohia analytically separated the high castes from women, shudra, Dalit, Muslim and adivasi (‘indigenous’) and underscored the political necessity of marriages between shudra and dvija, while disrupting the rift between manual and brain work, which contributed to the formation, rigidification and violence of caste.
catastrophe theory A branch of ‘bifurcation theory’, which is itself a branch of non-linear dynamic systems theory. Bifurcation theory studies how, in certain non-linear systems, there may be paths and shifts in behaviour dependent on small changes in circumstances or the current position of the system. One type is the sudden jump or catastrophe, where a dramatic change results from a small change in the parameters. Other forms of bifurcation include ‘hysteresis’, where the reverse path to some point is not the same as the original path, and ‘divergence’, where a small change leads the system towards a very different state (but not in a ‘jump’).

Bifurcation and catastrophe theory were developed by the French mathematician René Thom in the early 1970s (Thom, 1975). In human geography, several studies suggested that it could be used to understand settlement pattern changes, both in terms of the sudden emergence and growth of cities and the sudden collapse of layers in a central place system (for a review of these and other studies, see Wilson, 1981). The difficulty with these, and with many other suggested applications in the social sciences, is that they were speculative and one had to assume particular non-linear relationships and parameters to generate a system subject to catastrophes, and the perspective has not been as productive as many originally hoped. The most detailed and analytical developments in human geography have been those by Wilson, which add dynamics in the classic retail, gravity and urban structure models and explore potential bifurcations. Like its relative chaos theory, catastrophe theory is now treated as part of the wider complexity theory.

categorical data analysis A family of quantitative methods in which the variables are gauged at a low scale of measurement. Such variables may be binary categories (male/female; rich/poor), ordered multiple categories (as in a Likert scale such as, unhappy, neutral, happy), unordered multiple categories (travel to work by car, foot, train, cycle), or a count (the number of crimes in an area). Such data often arise through survey analysis in which answers to questions are limited to a number of categories. Until the 1970s, analysis of such data was limited to simple description in a cross-tabulation, testing for independence of variables through such procedures as chi-square, and assessing association with a range of measures of correlation such as Cramer’s $V$ and Yule’s $Q$. More recently, a full-scale modelling approach has been developed for such data in a regression-like framework.

All regression models consist of three components: the response or outcome variable; a function of the predictor or explanatory variables; and a random term that represents the stochastic variation in the outcome variable that is not accounted for by the predictors. In a standard regression model the response is a continuous variable that is related to the predictors in a linear (straight-line) fashion (the so-called ‘identity link’). With such a continuous outcome, the random term is usually assumed to follow a normal distribution and is summarized by an estimate of the unexplained variation, such as the variance. In categorical data analysis, in what are known as generalized linear models, the response is not continuous but discrete, the link between outcome and predictors is non-linear, and the random distribution is not normal but takes an appropriate distribution, depending on the scale of measurement of the dependent variable.

A number of key members of the family are defined by different types of measurement for the response variable. One that is binary or a proportion with a relatively small absolute denominator (e.g. the unemployment rate for small areas) requires a logit link and a binomial distribution; this is known as the logit regression model. Multiple categories are usually analysed with logit link and a multinomial distribution. Responses which are counts are usually analysed with a logarithmic link and a Poisson distribution: this is known as the Poisson regression model. Such models also offer a very flexible approach to longitudinal data analysis, called discrete time analysis, in which the response is whether or not an event (e.g. marriage/separation/divorce) occurred in a specified time-period.

This model-based approach allows assessment of the relationship between an outcome and a predictor variable (which may be continuous or categorical), taking account of other predictor variables. It is possible to test for relationships, derive overall goodness-of-fit measures and use diagnostic tools as part of exploratory data analysis for assessing whether the model’s assumptions have been met. There is now a wide range of software
CELLULAR AUTOMATA

FOR QUANTITATIVE ANALYSIS. This is vital, as the procedures used to calibrate models do not permit exact analytical solutions as in standard regression, but require an iterative approach, which can be computationally expensive. KJ

cellular automata Models of spatial phenomena, usually comprising a raster grid of cells, each of which has a value representing its present ‘state’ on a variable of interest. Algorithms with theoretically derived rules are applied to the initial system configuration to simulate changes. Run many times (each run is termed a ‘generation’), the algorithm produces an evolving pattern. A classic example is the well-known ‘game of life’, in which all cells are initially identified as either alive or dead (Conway, 1970); its algorithm’s rules specify that, for example, if any cell has fewer than two live neighbours, it too will die.

Cellular automata have been used for several decades in human geography to simulate spatial patterns and change – as in Torsten Hagerstrand’s original work on the diffusion of innovations (see Morrill, 2005). Developments in computer technology, especially geographic information systems and geocomputation, have enabled large-scale use of cellular automata models to simulate a wide range of environmental and other geographies (cf. agent-based modelling). RJ

census An enumeration, usually undertaken within the state apparatus, to provide needed data for state purposes. The Latin word census translates as ‘tax’, giving a clear indication of the purpose of such enumerations, the first of which are believed to have been taken in Egypt some 3,000 years ago. Many ad hoc censuses were taken before the nineteenth century – as with the 1086 Domesday book in England. Since then, an increasing number of countries have conducted regular (usually decennial) censuses as part of the development of statistics to inform the ever-widening range of government decision-making (Cullen, 1975). Censuses of population and housing are the most common, but separate censuses of, for example, agriculture, construction, (local) governments, manufacturing, mining and retailing have been held. A few countries – mainly in Scandinavia – have replaced censuses by continuously updated, geocoded population registers.

Censuses are constitutionally mandated in some countries. In the USA, for example, Section Two of the First Article states that ‘Representatives and direct taxes shall be apportioned among the several states . . . according to their respective numbers’: the first census was to be conducted within three years of the constitution’s acceptance, and ‘within every subsequent term of ten years’. They have been conducted decennially since 1790, and their findings have sometimes been hotly disputed because of their implications – as with the allocation of seats to the US House of Representatives after the 2000 census (Johnston, 2002: on the history of the US Census, see Eckler, 1972).

Although the primary role of a census is to collect factual information to inform public policy – both current and future (such as population projections) – nevertheless they cannot be considered ‘neutral’ tools. The data that they collect all refer to categories (occupational class, ethnicity etc.) that are social constructions, whose nature is determined by some theory of what should be measured, and how – as with the main ethnicity categories now used in the US Census (White; Black or African-American; American Indian and Alaskan Native; Asian; Native Hawaiian and Other Pacific Islander; Hispanic or Latino Origin) which dominate discourse about race and ethnicity there (Robbin, 2000; Yanow, 2002). Early US censuses generated considerable conflict between northern and southern states over counting slaves: southerners wanted to count them, because they would boost their entitlements to federal revenues and representation; northerners opposed to slavery were against. Eventually a compromise was reached, and slaves were counted as three-fifths only of ‘all other persons’ until after the Civil War. ‘Indians not taxed’ were excluded entirely until 1936. A similar situation obtained in Australia, whose original constitution – passed in 1900 – included ‘In reckoning the numbers of the people . . . aboriginal natives shall not be counted’. This remained the case until 1967, when voters overwhelmingly approved (91 per cent in favour: voting is compulsory in Australia) a referendum including the requirement that Aboriginals ‘be counted in reckoning the population’.

Just as there is a politics and a sociology of official statistics, including censuses (on which see several chapters in Alonso and Starr, 1987), so there is also a politics and sociology of their use. Data can be deployed in a variety of ways to sustain particular cases, including
partisan political projects – as illustrated by the use of 2001 census data in the UK to portray the country’s changing ethnic geography in ways that, while not wrong, emphasize findings that sustain a particular case (Dorling, 2005; Johnston and Poulsen, 2006).

The conduct of censuses is a major administrative task involving the distribution to and collection of forms from every address in the country, followed by the collation of large volumes of data. That administration is in almost every case geographical in nature: the country is divided into small areas (variously termed ‘collectors’ districts’, ‘enumeration districts’, etc.) in each of which data collection is overseen by a trained administrator (a role partly eliminated in some cases by use of postal and/or on-line questionnaires). Those small areas may also be deployed as reporting units, with data made available to users at very fine spatial scales. (The average collection district at the 2001 New Zealand census contained 106 persons, for example.) Elsewhere, the smallest reporting units are specially designed to provide information about NEIGHBOURHOODS in urban and separate settlements in rural areas, as with CENSUS TRACTS in the USA. For the 2001 UK census, geographers were involved in designing a three-level hierarchy of output areas which are relatively homogeneous on two criteria – dwelling type and tenure – as well as meeting size and shape constraints and fitting within local authority boundaries: their average populations were 297, 1,513 and 7,234 persons, respectively (Rees, Martin and Williamson, 2002).

Although an increasing number of census authorities release data at such small spatial scales, thereby facilitating detailed geographical analyses (cf. FACTORIAL ECOLOGY; SEGREGATION; SOCIAL AREA ANALYSIS) – some of value to policy-makers, as in the identification of areas of SOCIAL EXCLUSION within cities towards which programme money may be directed – a major purpose of a census is to provide information about and for sub-national governmental and administrative units. These then form the context of much geographical analysis although geographers have been employed to define other spatial architectures for data dissemination that are commensurate with the contemporary spatial structure of economy and society, which may not be the case with administrative areas: examples are the use of COMMUTING data to define METROPOLITAN AREAS in several countries.

Although the nature of the data collected and the spatial units for which they are released are important constraints to SPATIAL ANALYSIS, nevertheless censuses provide a wealth of information that has been deployed by geographers and others to portray many aspects of SOCIETY – not least through the production of atlases (e.g. Dorling and Thomas, 2004) notably, though not only, in POPULATION, SOCIAL and URBAN GEOGRAPHY. In addition, census authorities are increasingly providing a wider range of material: public-use micro-samples of entirely anonymized individual records are released in some countries, for example, which may be linked across censuses to facilitate LONGITUDINAL DATA ANALYSES. In some countries, too, the original manuscript census returns are made available (including on the internet), perhaps 100 years after they were collected, allowing detailed analyses in HISTORICAL GEOGRAPHY not previously feasible.

census tract  A small areal unit, containing a few thousand residents, used to collect and report CENSUS data. The first tracts were defined by the US Bureau of the Census in 1920 to approximate natural areas or NEIGHBOURHOODS, providing useful data for analysing urban social geography (cf. SOCIAL AREA ANALYSIS). Many censuses now use a similar spatial architecture – with varying terminology; some report data for areas with only a few hundred residents. Most tracts and comparable areas are designed for logistical convenience, although those for the 2001 England and Wales census were defined by geographers to produce areas with different housing characteristics (Martin, 2002).

central place theory A theoretical statement of the size and distribution of settlements within an urban system in which marketing – especially retailing of goods and services – is the predominant urban function. The theory assumes that both customers and retailers are utility-maximizers, making it a normative statement against which actual patterns can be compared.

Of the two separate central place theories developed, Christaller’s (1933) has been most influential. It was based on two concepts: the range of a good – the maximum distance that people will travel to buy it; and the threshold for a good – the minimum volume of sales necessary for a viable establishment selling that good (or a bundle of linked goods, such as groceries). In order to maximize their utilities, retailers locate establishments to be as near their customers as possible and customers visit the nearest available centre: in this way, expenditure on transport costs is minimized and spending on goods and services maximized.

On a uniform plane with a uniformly distributed population, Christaller showed that application of these two concepts produced a hexagonal network of central places housing the establishments, organized in a hierarchy whose number of levels reflected the number of goods/services with similar range and threshold values (he identified seven). Each was centrally located within its hinterland, with those at the hierarchy’s lowest level having the smallest number of establishments and serving the smallest hinterlands, and thus most widely distributed. The ways in which smaller settlements nested within the hinterlands of larger ones depended on a further set of principles. Christaller identified three (as shown in the figure). The marketing principle \((k = 3; a \text{ in the figure})\) minimizes the number of settlements so that each is at the meeting-point of three hexagonal hinterlands for centres at the next hierarchical level up: the number of centres in each order is 1, 2, 6, 18, 54, 162 and 486. According to the transport principle \((k = 4; b \text{ in the figure})\) the goal is to minimize the length of roads joining adjacent places. Each settlement is located centrally on the boundary line between the hexagonal hinterlands of two places in the next highest order hierarchy, and the number of centres is in the ratio 1, 2, 8, 32, 128, 512 and 2,048. Finally, the administrative principle \((k = 7; c \text{ in the diagram})\) has each lower-order settlement and its hinterland nested exclusively within the hinterland of a single settlement in the next highest order, producing a much larger number of places in the ratio 1, 6, 42, 294, 2,058, 14,406 and 100,842.

Lösch’s (1940) model was much less restrictive than Christaller’s. Rather than bunch all functions into seven ‘orders’ he treated each as having a separate range, threshold and hexagonal hinterland. Where feasible, functions were clustered into settlements but all central places with certain functions in them need not – as in Christaller’s scheme – also contain all of the functions with smaller ranges and thresholds. This produced a much wider range of settlements in terms of size and complexity of business profiles: whereas Christaller’s theory produced a stepped hierarchical urban system, Lösch’s was consistent with a more continuous distribution of urban sizes.

Central place theory was a major stimulus to work in the early years of geography’s quantitative revolution: it was described by Bunge (1968, p. 133) as ‘geography’s finest intellectual product’. Christaller’s work, in particular, was the basis of much research into the size and spacing of settlements and into consumer behaviour (both inter- and intra-urban), and also as the basis for planning settlement patterns – not only in the anodyne cases of new settlements in the Dutch polders and the distribution of new shopping centres in cities, but also in the violent resettlement of Eastern Europe as part of the Nazi holocaust.

With greater mobility and customer choice available in many, more developed, societies, the underlying assumptions are increasingly irrelevant and the theory remains more as an exemplar of modelling during that period of geography’s history than as a paradigm for understanding contemporary settlement patterns, although it is one of the theories ‘rediscovered’ in the new economic geography. (See also periodic market systems.) RJ

centrifugal and centripetal forces Terms adapted from physics by C.C. Colby (1932) to describe two countereacting forces generating intra-urban land-use changes. Centrifugal
central place theory  The size and spacing of central places, plus their hinterlands (left) and routes (right), according to three variants of Christaller’s model: (a) the market principle, which minimizes the numbers of centres; (b) the transport principle, which minimizes the road length; and (c) the administrative principle, in which hinterlands are nested hierarchically.
forces push residential, business and other users away from the congested, polluted, high-density and expensive inner-city areas towards the suburbs and beyond (cf. deconcentration: see COUNTER-Urbanization; Decentralization; Sprawl), whereas centripetal forces attract them towards the centre for the benefits of ACCESSIBILITY and AGGLOMERATION (cf. Gentrification). The balance of these two forces at any time determines the changing urban morphology.

**chain migration** A term used to describe **migration** that occurs in a sequence, when the movement of one person causes others to follow. It is a major component of **network-based** theories of migration. Chain migration typically begins at the family scale, with a single person moving to a new place in search of better opportunities. Once settled, that person facilitates the migration of other members of the nuclear or extended family (Hugo, 1994). In time, the migration network extends to friends and acquaintances as well. As this occurs, migration becomes self-perpetuating. New arrivals are assisted by those who have already learned to cope in the receiving society (Castles and Miller, 2003). This is particularly effective in the process of finding shelter and work, and newcomers generally live in close proximity, and take similar jobs to those who help them. This process leads to the development of immigrant enclaves in housing and labour markets, as Banerjee (1983) has shown in the case of internal migration in India (cf. Segregation and segmented Labour Market). Chain migration also fosters financial transfers, or remittances, between immigrants and family members who are still residents of the source country, as well as other forms of transnationalism (Levitt and Glick Schiller, 2004).

From the point of view of receiving countries, the chain migration process can be thought of as an ‘immigration multiplier’, in the sense that each individual immigrant is likely to generate the entry of several others over time (Jasso and Rosenzweig, 1986). Once established, these networks develop routinized systems of movement that can even circumvent state authority (Bocker, 1994). It is widely believed, for example, that chain migration has been an essential ingredient in the entry of the approximately 12 million undocumented immigrants residing in the USA. This insight has often been used by critics of immigration, who argue that the combination of the self-perpetuating nature of chain migration and the multiplier effect will cause a geometric increase in immigration (cf. Goering, 1989). However, it is worth remembering that social networks are just one contributing factor in migration, and that other factors, notably economic differentials between countries and various forms of violence, are structural causes of migration.

**Suggested reading** Castles and Miller (2003); Hugo (1994).

**chaos theory** A branch of non-linear mathematical theory dealing with dynamic systems which exhibit aperiodic behaviour that is sensitive to initial conditions and is unpredictable in detail. Such sensitivity to initial conditions is often referred to as the ‘butterfly effect’, with the illustration that the flapping of a butterfly’s wings in one part of the world might, through tiny impacts on the atmosphere, have major impacts elsewhere in the world. The behaviour of systems that exhibit chaos may appear to be random, even though the system is deterministic in the sense that it is well defined and contains no random parameters. This technical use of the word ‘chaos’ is at odds with everyday language, which suggests complete disorder. Chaotic systems are ‘orderly’ in being deterministic, and also usually have well-defined system structure and statistics. A very simple example of such a system is provided by May (1973) in his standard logistic model of population growth:

\[ X_{t+1} = aX_t[1 - bX_t/a], \]

where next year’s population \( X_{t+1} \) is dependent on the current population \( X_t \) and parameters \( a \) and \( b \). The system exhibits very different behaviours depending on the values of \( a \): if \( 1 < a < 3 \), then \( X_t \) tends towards a stable equilibrium population. If \( a > 4 \), then there is a divergence to minus infinity (a total collapse of the system), but for values of \( a \) between 3 and 4, there are interesting dynamics: if \( 3 < a < 3.8495 \), then \( X_t \) oscillates with a regular, periodic frequency, but if \( 3.8495 < a < 4 \), then the oscillations are chaotic, with no regular frequency.

Chaos theory was a popular and much-vaunted term for a time, but, like the related mathematical systems of catastrophe theory, it is usually now treated as part of the wider arena of complexity theory, and further reading will be found under this term.

**Chicago School** The first sociology department in the USA (founded in 1892), located
at the University of Chicago, where scholars including Robert Park, Louis Wirth and Ernest Burgess established an agenda, approach (HUMAN ECOLOGY) and METHODOLOGY for the study of urban areas. From the 1910s through to the 1930s, the scholars at the Chicago School set out to study the city as ‘a product ... of human nature’ (Park, 1967 [1925], p. 1). Indeed, the Chicago School sociologists saw the city as ‘the natural habitat of civilized man [sic]’ (Park, 1967 [1925], p. 2). Fundamental to their theories about urban life was an expectation of social organization and control. They anticipated that land use patterns in a city would reflect ‘an orderly and typical grouping of its population and institutions’ (Park, 1967 [1925], p. 1), and sought to study these systematically. Chicago School sociologists developed detailed descriptions of urban life based on field observations of Chicago. In doing so, they advocated that ETHNOGRAPHIC methods drawn from anthropology be applied to urban cultures (Park, 1967 [1925]). Their in-depth observations were hindered by a tendency to generalize from the single Chicago case, but their emphasis on observation remains influential in COMMUNITY research.

The Chicago sociologists drew upon Darwin’s theories of order and ‘cooperative competition’ among species in a shared TERRITORY and applied them to humans in urban environments (Park, 1936). The concept of community articulated the biotic level of social organization, which correlated for the Chicago School scholars with RACE and ETHNICITY (Theodorson, 1961; Knox, 1994). Social communities as defined by ethnicity formed ‘natural areas’ that were segregated from one another (Park, 1967 [1925]). By applying biological METAPHORS to sociology, Park and his colleagues were creating a scientific justification and legitimation for the study of social phenomena (Entrikin, 1980). At the same time, however, their naturalizing of racialized social communities fostered and reinforced notions of a GHETTO that was both voluntary and temporary: ‘they never saw the difference between the ethnic enclave and the black ghetto’ (Philpott, 1991 [1978], p. 141). Further, Philpott argues that with the exception of the ‘Black belt’ African-American ghetto, the natural areas (social communities) about which the Chicago sociologists wrote were never as homogeneous as some of their writings suggested.

Well-known and influential studies of ‘natural areas’ that were developed by the Chicago School faculty and their students include Zorbaugh’s The gold coast and the slum (1929) and Frazier’s ‘Negro Harlem: an ecological study’ (1937). Perhaps the most famous among the writings of the Chicago School, however, is that of Ernest Burgess on ‘The growth of the city’ (1967 [1925]). In it, he offered a descriptive MODEL of urban structure to explain land use, urban growth and NEIGHBOURHOOD change. He posited urban expansion based on differentiation of land uses and competition among those uses (a basic premise also articulated in the VON THÜSEN MODEL and also other land-use models by Hoyt (1939) and Alonso (1960), among others). His ZONAL MODEL represented the city as a series of ‘concentric circles’, or zones. The central zone at the core of the city was the CENTRAL BUSINESS DISTRICT (CBD), called the ‘loop’ in his model due to the influence of Chicago as the empirical case study. Successive zones were described as residential areas, differentiated from one another based on categories of ethnicity, social CLASS and housing type.

The process of urban expansion was explained by Burgess (1967 [1925]) in terms of the INVASION AND SUCCESSION of one zone (predominant land use) into the next outer zone adjacent to it, with physical expansion of the city the result. The MOBILITY assumed in the model to be inherent to urban expansion was seen by Burgess to be both a stimulus to urban growth and the source of instability, especially in lower-income and immigrant communities. Thus, CRIME, POVERTY, HOMELESSNESS and social and psychological instability were seen as naturally occurring phenomena in the zone of transition just outside of the expanding CBD (Burgess, 1967 [1925], p. 54).

Burgess’ model, and the overall goals of the Chicago School to study urban life, community and organization, have been extremely influential in urban studies generally, including URBAN GEOGRAPHY. The inherent (and explicit) SPATIALITY of Burgess’ model of urban growth is appealing to geographers. Terms such as CBD are ubiquitous in the field. Yet the assumptions underlying the model and its theory of growth, particularly the naturalization of RACE, ETHNICITY and social problems such as CRIME and HOMELESSNESS, limit its use and applicability.

The Chicago School is clearly situated in and thus limited by its time and place – because of its reliance on human ecology and Darwinian METAPHORS, and upon the city of Chicago as the main CASE STUDY. Yet Park’s (1967 [1925]) original description of an
CHILDREN

agenda for research included POPULATION and DEMOGRAPHY, LAND USE, patterns of home ownership and MIGRATION, community development and character, neighbourhood history, occupational and class mobility, social unrest and social control (including POLICING and urban policies). Many of these topics remain of vital interest to urban geographers, and draw upon ideas from the Chicago School about PATTERN, PROCESS and community, although our contemporary approaches to and theories of these topics are necessarily different.

children A burgeoning area of scholarship in HUMAN GEOGRAPHY that encompasses notions of children as active producers of SPACE, as geographical subjects and as environmental agents, at the same time as it recognizes children’s limited MOBILITY, the peculiarities of their exposure to various environmental degradations and HAZARDS, and the mediated nature of their spatial engagements.

The earliest work in the field, pioneered by James Blaut and the psychologist David Stea, addressed the ‘ontogeny of environmental behavior’ by looking at children’s geographical learning, especially their understandings of spatial relationships, mapping skills and PLACE knowledge (Blaut and Stea, 1971, p. 387). Their Place Perception Project (1968–71) spurred much generative work in the field, including Roger Hart’s (1979) landmark study of children’s place experience, Denis Wood’s fascinating research on the relationship between young people’s spatial behaviour and their cognitive MAPS, and research on such issues as children’s differentiated access to the outdoor environment or ‘home range,’ their understanding of environmental processes and human–environment interactions, and their ability to negotiate aerial photographs. At about the same time as Blaut, Stea and their colleagues at Clark University were researching children’s acquisition of environmental knowledge, William Bunge (see Bunge et al., 1971) was launching the Detroit Geographical Expedition, which examined the effects of noxious and deteriorated environments on children’s well-being, and developed projects of environmental ACTIVISM around the uneven geographies of people’s everyday lives and children’s exposure to problems rooted in these geographies. These two streams of work – not, coincidentally, by radical geographers – set the stage for much subsequent scholarship on children’s geographies and the geographies of children, even as some of their key practitioners were marginalized from the field.

As geographers have continued to address the development of spatial cognition, mapping skills and environmental learning, there has been an ongoing debate about whether mapping represents a cultural universal that children share from earliest childhood, as Blaut and Stea and their colleagues have argued, or is dependent on cognitive development, as Roger Downs, Lynn Liben and their colleagues have argued. While much of this debate has concerned children’s relative preparedness for acquiring spatial concepts and mapping skills (and thus was an argument about the role of geographical EDUCATION at different ages), it was animated by the principals’ understandings of the nature of Piagetian developmental psychology and what Blaut considered its IDEALIST underpinnings. Both sides recognized children’s embrace of geographical concepts, and advocated their being taught mapping and spatial skills in all phases of their education, agreeing that it would not only be a cornerstone of enhanced geographic literacy but contribute to cognitive development and learning in other arenas (Blaut, 1997; Liben and Downs, 1997; cf. Matthews, 1992). Despite this conclusion and the decades of scholarship that support it, there remains a surprising disconnection between the work of scholars interested in geographical or environmental EDUCATION and those who look at children’s place experience and their acquisition of environmental knowledge and spatial skills.

Work on children’s geographies has been developmental, ecological, milieu focused, comparative and concerned mostly with the global North. As the field evolved, its concerns expanded to include children’s understanding and experience of place (Hart, 1979; Matthews, 1992; Wood and Beck, 1994), their knowledge of environmental processes and human–environment relations (Kates and Katz, 1977; Hart, 1997; Katz, 2004), the social ecologies of their environmental interactions (Ruddick, 1996; Valentine, 1997; Aitken, 2001) and studies of particular children’s environments, such as playgrounds, schools, parks and NEIGHBOURHOODS (e.g. Skelton and Valentine, 1998; McKendrick, 1999). In tandem with broader disciplinary concerns, research focused on children and
geography has shifted to address new arenas of experience and has recognized the socially constructed nature of childhood. Recent work has examined children and the electronic environment (Holloway and Valentine, 2000); children as environmentalists (Hart, 1997; Holloway and Valentine, 2000); aspects of place experience, such as fear, constriction and surveillance, which have peculiar ramifications for young people (Valentine, 1997; Katz, 2005; Pain, Grundy, Gill et al., 2005); the emotional geographies of youth and childhood; identity formation and issues of difference; landscapes of consumption; and questions of youth participation and rights (Hart, 1997). A growing number of geographers are attending to children’s geographies in the global south and addressing the questions of difference that they raise (Holloway and Valentine, 2000; Katz, 2004).

In geography as in other disciplines associated with the ‘new social studies of childhood,’ children are recognized as subjects and social actors in their own right at the same time as they are both becoming something else and subject to structural forces beyond their control. Children and young people are seen to shape their own and others’ lives, the social formations in which they live and the social construction of childhood itself. While children’s experiences are often cast in relation to adults, geographers and others are clear that age and life course are not the only differences that structure young people’s experiences. Geographers examine how differences of gender, class, nation, race, embodiedness and sexuality separately and in conjunction affect young people’s experiences and understandings of the world (Skelton and Valentine, 1998; Holloway and Valentine, 2000). Childhood is now recognized as a social construction that varies historically and geographically, and scholars seek to understand it for itself rather than as a stage on the road to adulthood. If research only recently moved away from the latter perspective and its focus on the practices and processes of socialization, it has long been the case that scholarship on children’s geographies has treated children methodologically as social actors rather than as objects of learning or vessels for knowledge. This perspective can be readily seen in the methodologies adopted – and invented – for studying children’s geographies. Beginning with the early work of Blaut and Stea and their students and colleagues, children have been asked to navigate actual and representational geographies, make maps, engage in landscape modelling, enact ‘geodramas’, take photographs and make films, keep journals, write narratives, lead walks and – more recently – shape the research itself. These strategies have long complemented research methods such as surveys, interviews, participant observation and the like in children’s geographies.

In the past decade, children’s geographies has been recognized as a vibrant sub-field of the discipline. This achievement was marked by the inauguration of an international journal, Children’s Geographies, the online revival of the Children’s Environments Quarterly as CYE (Children, Youth, and Environments), the establishment of an IBG/RGS Working Group on the geographies of children, youth and families; the publication of a number of edited collections (e.g. Skelton and Valentine, 1998; Holloway and Valentine, 2000) and monographs (e.g. Matthews, 1992; Ruddick, 1996; Aitken, 2001; Katz, 2004); and the proliferation of specialized international workshops, conferences and special sessions at geography meetings. Perhaps the significance of this sub-field to the broader discipline, as much as its own ‘coming of age’, can best be seen in how a growing number of geographers have refracted issues such as globalization, gentrification, migration or homelessness, and theoretical constructs such as scale, social reproduction or the production of space through the lens of childhood and youth (e.g. Ruddick, 1996, 2003; Katz, 2004).

Chinatown Chinese peoples living in cities beyond China have formed compact and comparatively exclusive settlements known as Chinatowns, in which they have resided, worked and traded (Benton and Gomez, 2003). Following the classic ideal-type Chinatown formulated by Lawrence Crissman (1967) based on studies of Chinese societies in South East Asia and North America, scholars of the overseas Chinese such as William Skinner and Wang Gungwu have portrayed Chinatown as an extension of homeland practices, where principles of social organization based on descent, locality and occupation that had ordered rural life in China were transplanted to overseas urban settings. In many countries, Chinatown demography was fuelled by an initial phase – taking place during the nineteenth and the first half
of the twentieth centuries – characterized by either indentured labour systems or kinship-based CHAIN MIGRATION (predominantly of men), followed by a post-Second World War phase during which a ‘bachelor society’ was gradually transformed by the presence of more female migrants and family immigration (Chen, 1992; Benton and Gomez, 2003). Largely self-organizing entities, socio-political life and the provision of cradle-to-grave services in these transplanted communities were anchored, to different extents in different communities, by Chinese associations based on clan, surname, dialect or provenance. Portrayed as an immigrant neighbourhood or an ethnic enclave, Chinatown is identified as a reception area for newcomers, an agglomeration of ethnic businesses (including ‘illegal’ or ‘immoral’ practices such as drug trafficking, gambling and prostitution) serving its ‘own kind’, and the focal point of a well-knit community in a foreign land. The Chinatown depicted in this vein is essentially an outpost of a foreign country, comprising a DIASPORA of unassimilable foreigners.

Recent scholarship has challenged our understanding of Chinatown in at least three ways. First, Chinatown is not just an exported structure, but the product of host society reception, including colonial labour policies in some instances and racial discriminatory and discursive practices more generally. In colonial cities of South East Asia, Chinatown as a racial categorization and spatial container to accommodate the Chinese emerged as part of colonial urban planning, and often featured in colonial discourses as a landscape of filth, pestilence and moral decay (Yeoh and Kong, 1994). In Western contexts, by placing the idea of Chinatown at the centre of RACE-definition processes, Anderson (1987, p. 581) argues that ‘Chinatown is a social construction with a cultural history and a tradition of imagery and institutional practice that has given it a cognitive and material reality in and for the West.’

More than a PLACE-NAME or a social community, Chinatown is also part of the IMAGINATIVE GEOGRAPHIES underpinning white European cultural HEGEMONY (see CHINATOWN).

Second, using Chinatown as a spatial reference for an essentialized Chinese IDENTITY or ‘chopsticks culture’ fails to recognize differences of class, sub-ethnic affiliation and cultural history among members of Chinese communities. Social and economic mobility, generational change and the influx of later arrivals from different parts of mainland China, Hong Kong, Taiwan and other Chinese communities have transformed closed social structures and introduced diversity in terms of CLASS, occupations, educational backgrounds, political affiliations and even ethnic consciousness among those identified with Chinatown (Chen, 1992; Kwong, 2001; Christiansen, 2003).

Third, against portrayals of Chinatown as an enclave economy that defies integration into the mainstream, Zhou (1992) argues that immigrant Chinese in Chinatowns in the US context are able to draw upon social capital and networks to surmount structural barriers and facilitate socio-economic mobility. From this perspective, Chinatown as an ethnic enclave provides a mechanism for eventual immigrant incorporation into mainstream society.

Chinatown landscapes are also increasingly revitalized for the purposes of HERITAGE TOURISM or promoted as gentrified, conservation settings to enhance urban aesthetics in globalization cities. Along with other ethnic neighbourhoods ranging from Koreatown to Little India, Chinatown as the inscription of race in place has continued to evolve in tandem not only with IMMIGRATION dynamics but with the politics of PLACE.

**chorology/chorography** The study of the variation in the Earth’s surface from place to place (see also AREAL DIFFERENTIATION). Chorology represents the oldest tradition of Western geographical enquiry. It was first codified by Hecataeus of Miletus in the sixth century BCE and systematized by Strabo in the seventeen books of his Geography, probably written between AD 18 and 24. The geographer, he wrote, is ‘the person who attempts to describe the parts of the earth’ (in Greek, chorographin). The two key words were ‘describe’ and ‘parts’: in effect, Strabo was recommending what would now be called REGIONAL GEOGRAPHY as the core of geographical reflection. He was not interested in chorography for its own sake, but intended it to serve a higher purpose. The production of geographical knowledge was an indispensable complement to political and moral PHILOSOPHY, because it provided a material ground for understanding truth, nobility and virtue. For this reason, Strabo’s geography was fundamentally concerned with human activities. It was also directed towards political and social
ends, and paid considerable attention to the interests of the political ruler and the military commander. Although Strabo was born in Greece, he enjoyed the patronage of Augustus and did most of his work in Rome, so that his Geography can be read as an attempt to explain the post-Republican world (the inhabited world, or ECUMENE) to the citizens of the new Roman Empire (Dueck, 2000). Chorography was not supposed to provide a comprehensive gazeteer or regional inventory: it was partial and purposive, and Strabo focused on Rome and began with EUROPE because ‘it is admirably adapted by nature for the development of excellence in men and governments’ (van Paassen, 1957, pp. 1–32).

Strabo’s conception of geography was challenged by Claudius Ptolemaeus (or Ptolemy) round about AD 150. In his view, the purpose of geography was to provide ‘a view of the whole head’ and this meant that he separated geography from chorography, which had the purpose ‘of describing the parts, as if one were to draw only an ear or an eye’. As this passage implies, for Ptolemy, graphein did not mean describing but drawing and, specifically, mapping. Ptolemy’s ‘geography’ was geodesy and CARTOGRAPHY, and he preferred to leave out everything that had no direct connection with that aim: ‘We shall expand our “guide” for so far as this is useful for the knowledge of the location of places and their setting upon the map, but we shall leave out of consideration all the many details about the peculiarities of the peoples’ (van Paassen, 1957, p. 2).

The distance between Strabo and Ptolemy could not be plainer, and it is indelibly present in the modern constitution of GEOGRAPHY too. As late as the seventeenth century, Strabo and Ptolemy continued to provide the main models for European geography. The usual distinction was between a Special Geography, devoted to a description of particular regions, and a General Geography, mathematically oriented and concerned with the globe as a whole. The premier illustration is the work of Bernhard Varenius, who published both studies in Special Geography and his famous Geographia Generalis, in which, for the first time, geography sought to engage with the ideas of Bacon, Descartes and Galileo (Bowen, 1981).

The modern case for geography as chorology was argued most forcefully by Hartshorne (1939), and following the subsequent debate over EXCEPTIONALISM in geography – and despite the nuances and qualifications that Hartshorne had registered – chorology was often used in polemical opposition to SPATIAL SCIENCE (cf. Sack, 1974a). But the temper of the original version, with its acknowledgement of the importance of POWER and philosophical reflection (cf. Casey, 2001, p. 683), is a forceful reminder of the continuing need to attend to the politics of geographical enquiry, while Koelsch (2004) has insisted that contemporary attempts to understand the heterogeneous geography of the world still have much to learn from ‘the place-based, cultural–historical model’ of Strabo.

**choropleth** A map that portrays a single distribution for CENSUS TRACTS, counties or similar areal units; portrays each areal unit as homogeneous; divides the data into discrete categories; and typically describes spatial variation of intensity data with a darker-means-more sequence of greytones. Readily rendered by mapping software, choropleth maps can present misleading patterns when based on count data, highly heterogeneous areal units, inappropriate CLASS INTERVALS or illogical sequences of colours (Brewer and Pickle, 2002; Monmonier, 2005). Although most choropleth maps depict quantitative distributions such as median income or the percentage rate of population growth, qualitative choropleth maps are useful for showing distributions such as dominant religion or form of government.

**chronotope** Translated as ‘time–space’ from its origins in Greek, the term is used to designate the spatio-temporal contexts and categories embedded within a text or other cultural artefact. The term was devised by Russian literary theorist and philosopher Mikhail Bakhtin (1895–1975) in the 1920s, partly influenced by the revolutionary transformation of physics by Einstein, Planck and others, and it was subsequently imported into literary history and cultural studies. In the most general terms, the idea of a chronotope acknowledges the inseparability of TIME and SPACE while deploying their unity to materialize concrete cultural formations. It is perhaps best to think of a chronotope as a kind of matrix that allows cultural analysts to situ-ate a work within its historico-geographical setting in order to facilitate its interpretation.
Bakhtin (1984, p. 246) offered the concrete example of the French literary salon as a key nineteenth-century chronotope, ‘where the major spatial and temporal sequences of the novel intersect’ in the works of Balzac and Stendhal. Not surprisingly, the term has been influential in theatre studies, with the stage providing an intuitive location for the observation of chronotopes in action, and theories of performance have developed these immanent geographical tropes still further by insisting on the contextual boundedness of human actions. In HUMAN GEOGRAPHY, Folch-Serra (1990) proposed a dialogical conception of landscape that derived directly from Bakhtin and promised to reconstruct the power-laden interactions ‘that alternately “anchor” and destabilize the “natural harmony” of a region’. This focus on the narration of landscape resurfaces in interdisciplinary studies of landscape and identity (Lehman, 1998), but the sense of diversity, dialogue and disputation that is crucial for any Bakhtinian approach is best exemplified by O’Reilly’s (2007) study of the unfolding micropolitical relations between competing voices and the co-production of gendered time–spaces of participation in development projects in North India. As she shows, and as the concept of a chronotope strongly suggests, struggles over meaning are also and reciprocally struggles over the production of distinctive time–spaces.

**citizenship** The rights and duties relating to an individual’s membership in a political community. In the past several centuries, the boundary of this community has been the nation-state and membership has implied some degree of integration into a common national heritage. In its early formulations, however, citizenship was understood as a set of rights and freedoms located primarily at the local scale. The expansion of individual freedoms (such as the right to work and habeas corpus) into a national institution was one of the key components of the growth of modern citizenship. It reflected a shift from local, communal relations and social rights rooted in village membership into a sense of a national community and of individual rights guaranteed by a state. This shift in scale from the local to the national and from communally sanctioned rights to those protected by the state is an absolutely fundamental aspect of modern citizenship, and one that is profoundly intertwined with the growth of industrial capitalism, liberalism and modernity in the West (Weber, 1978 [1922]; Turner, 1993; Marston and Mitchell, 2004).

As it has developed in British and North American societies, citizenship owes its modern legacy to a succession of legal and political rights and responsibilities originating in Britain mainly in the seventeenth century and continuing through to the present. According to T.H. Marshall, citizenship can be usefully periodized in terms of: (a) the eighteenth-century development of civil citizenship, which encompasses civil and legal rights, especially property rights; (b) the nineteenth-century expansion of political citizenship, which involves the rights to vote, to associate and to participate in government; and (c) the rise of twentieth-century social citizenship, which involves entitlements such as provisions for health, housing and education (see Mann, 1987, p. 339; Marshall and Bottomore, 1992). Marshall envisioned a continuous positive trajectory for citizenship in terms of the ongoing inclusiveness and expansion of universal rights, as well as the evolution of those forms of state welfarism (social citizenship) that guaranteed all members the chance to access those rights and participate in the politics of the community. Although his framework remains influential, Marshall has been criticized for his lack of attention to the experiences of women (Vogel, 1994; Walby, 1994), for the linear and evolutionary qualities of his model (Giddens, 1982), and for his unquestioned liberal assumptions relating to the positive integrative capacity of citizenship itself (see liberalism).

Like many mid-twentieth-century liberals, Marshall was a strong nationalist who conceptualized citizenship as corresponding with a specific state territory and as fundamentally linked with its economic development and cultural narratives. For him and many others, citizenship necessarily assumed both a sense of belonging and identity rooted in a shared national past and a commitment to the production and defence of its territorial borders. Over the past few decades, however, these types of assumptions have been overturned. As a result of the powerful new forces of globalization and transnationalism, both the national narratives of heritage and community and the state’s discrete and autonomous jurisdiction over territory and population have been called into question. One of the many new kinds of tensions that have erupted in this
period involves the meaning and practices of contemporary citizenship.

With the ever-increasing volume and speed of the flows characteristic of globalization, including those of trade, finance, commodities, information, ideas, culture and human beings, the ability of state actors to control and regulate border-crossings and their increasingly mobile populations has greatly diminished. At the same time, most states have maintained various kinds of power through new types of geopolitical alliances, new forms of disciplining and regulation of people across borders, and the development of new transnational or supranational institutions and practices of rule. In all of these assemblages of power, the meaning, status and practice of citizenship has remained a crucial and much sought-after prize, and it has been at the centre of multiple hegemonic struggles worldwide over the past two decades.

The scholarship on citizenship has burgeoned over the same time period, with hundreds of titles on different forms of citizenship, such as post-national, transnational, dual and multicultural. Those with an empirical bent have tracked the transformations in citizenship law in different national sites over this period and/or the numbers of immigrants or denizens who have become citizens, or whose status or benefits or rights have changed. Those leaning towards post-structuralism have written about the cultural qualities of contemporary citizenship, emphasizing in particular its multi-layered nature and/or the ways in which belonging and identity are morphing into something quite different from earlier nation-based understandings and assumptions. Many have also remarked on the different scales of citizenship, from supra-national (e.g. the EU) to sub-national (e.g. Basque) citizenship possibilities. Soysal (1994) argues that the development of both of these forms manifests the declining importance of national citizenship and the rise of new forms of post-national membership in Europe.

Almost all current scholarship engages with citizenship as a constantly evolving, non-linear formation that is tied to the development of modern nation-states as well as to the evolution of contemporary economic systems. In the West, it is inevitably interrelated with the form and logic of capitalist development. This said, it should be noted that the ways in which citizenship takes shape at different historical periods and in different places always reflect the actions of those to whom its transformation matters. State and economic restructuring responding to civic or popular action – whether it is of resistance or accommodation – shifts the terrain of rights, responsibilities and belonging on which citizenship is based, leading inexorably to new formations through time.

city The etymological roots of the term lie in the Latin civitas; it is related to the Greek polis, the Latin urbs, the French la cité, la ville, the Italian la città and the German die Stadt. Today, a more generic usage of the term refers to an urban demographic, economic and above all political and jurisdictional unit, usually bigger than a town. In the USA, cities are considered to have self-government granted by the states. In Canada, where municipal autonomy is more restricted, cities are under the constitutional jurisdiction of provinces. In the UK, reference is to a large town that has received title from the Crown.

Cities are usually trading centres and marketplaces. Their emergence is linked to the historical separation of non-agricultural work from the land (see urban origins). Ancient cities in the Indus valley, in Mesopotamia, Egypt and China were based on a hydrological agricultural economy, and were the seats of religious and military power, and the state. The built environment developed around a temple or ziggurat, and was walled for defence and internal control of the population. In ancient Greece and Rome, city-states (Athens, Rome) were cores of larger empires (Mumford, 1961; Benevolo, 1980). Medieval cities in Europe are often seen as the Western archetype of urban socio-spatial organization and the core of an urban-based network of trade systems (e.g. the German Hansa). During that period, cities were municipal corporations of free citizens embedded in – usually feudal – larger territorial units. Cities were seats of church power and of the emerging bourgeoisie, as well as the tightly organized artisan trades. Many cities became the location of the first universities.

Today’s most common image of cities is influenced by the industrial age. The industrial revolution led to the large-scale demographic concentration of working-class populations around manufacturing plants or industrial complexes, and housed in the typical tenement and rowhouse settlements of the nineteenth-century city. Industrial core
CIVIL SOCIETY

regions such as the British Midlands or the German Ruhr area became sites of rapid urbanization, creating regional agglomerations of industrial cities. In the USA, Chicago stands in as the prototypical industrial city that grew explosively around the turn of the twentieth century.

Improved transportation allowed longer commuter distances and suburbanization at the beginning of the twentieth century. The planned suburbanization and automobileization, as well as functional separation of land uses in particular, were ultimately considered a major contributor to the ‘fall’ of the modern city (Jacobs, 1992 [1961]; see suburb). The twentieth century saw metropolitanization and the rise of the megalopolis, a supercity stretching across several urban areas. City life now encompasses most areas of society as ‘urbanism as a way of life’ (see urbanism) becomes pervasive. Post-industrial cities now characterize most Western nations, as industries first moved to suburban locations and then to developing countries where – as in Korea, Brazil or China – renewed waves of urbanization and industrialization seem to repeat the history of the industrial city in Europe and North America.

In the global south, cities have often grown from colonial outposts into global trading centres (Hong Kong and Singapore). In Africa, Asia and Latin America today, cities grow dramatically, often largely on the basis of large-scale squatter settlements (see squatting) and informal urbanization. Cities have recently enjoyed renewed attention as a post-Westphalian system of global governance has restructured the role of nation-states, and as new types of global cities and megacities have begun to exert territorial, economic and political power at a global scale.

The city has been the object of much scholarly debate in geography and the social sciences. As David Harvey (1973, p. 196) has noted: ‘Urbanism may be regarded as a particular form or patterning of the social process. This process unfolds in a spatially structured environment created by man [sic]. The city can therefore be regarded as a tangible, built environment – an environment which is a social product.’ Urban theory of the twentieth century, strongly influenced by the work of German sociologist Max Weber (1958 [1921]) and the Chicago school of sociology (Park, Burgess and McKenzie, 1925; Wirth, 1938), tended to fetishize the city spatially as something that appeared distinct from society. Neo-Marxist and neo-Weberian critiques led to a new phase of studying the city in the 1960s and 1970s (Castells, 1972; Harvey, 1973; Smith, 1979b; Saunders, 1986; Lefebvre, 2003 [1970]), pointing to the notion that the modern city is an economic or administrative part of capitalist society and cannot be studied in separation from it. Castells influentially defined the city as the site of collective consumption and a site for social movement mobilization (Castells, 1972, 1983). A related strand of thought redefined the city as a product of urban growth machines and governing regimes interested in the increase in property values (Logan and Molotch, 1987). Whereas in the 1970s and 1980s ‘the city’ often became synonymous with the site of social crisis, pathology and delinquency, the postmodern turn in geography and urban studies reinvigorated the discussion on the city in the 1990s, as Los Angeles was temporarily viewed as the new ‘Chicago’: a distinct and pervasive model of urbanization in a globalized capitalist system (Scott and Soja, 1996; Dear, 2002; see postmodernism). As China’s cities grow in size and significance as global players, they have become the focus of increased attention at the beginning of the twenty-first century, while the sprawling megacities of the global South are considered to be on a trajectory different from the ones in the West and in the North.

Although the death of the city had been predicted as a consequence of the development of transportation and information technologies that allegedly make agglomeration less necessary and less likely, the opposite has occurred in the past decade: economic power has been re-concentrated in cities as a new wave of re-centralization of people and economic activities has led to a ‘fifth migration’ to urban centres (Fishman, 2005). Much of this had to do with a distinct process of ‘metropolization’, a state growth strategy that concentrates specifically on cities. As a consequence, cities have been rediscovered as the site of ‘creative industries’, but also as the contested space of social struggles, gentrification and displacement.

**civil society** Understood as a domain of associations autonomous from the state, this concept has been critical to the history of Western political thought. Originally posited in Europe in the eighteenth century to denote
a realm of social mutuality, the idea of civil society increasingly came to signify aspects of social existence that occur beyond the state. In its different uptakes, the concept of civil society has been central to the development of both the liberal-parliamentary tradition and the socialist-Marxist one. Although demarcated differently by theorists of the French, German and Scottish ENLIGHTENMENTS, all attempts to articulate a notion of civil society shared the perceived tensions between the public and the private, the social and the individual, collective responsibility and self-interest, and state prerogatives and individual freedoms. But Italian Marxist Antonio Gramsci offered an alternative perspective. In his Prison Notebooks (1971 [1929–35]), he explored aspects of the state and civil society that liberal theory ignores – namely, the relations of power and influence between political society (what liberal theorists call ‘state’ or ‘government’) and civil society (the ‘private sector’ in liberal vocabulary), which mutually reinforce each other to the advantage of certain strata and groups. Contra LIBERALISM, Gramsci recognized civil society as the terrain of Hegemony rather than freedom.

The contemporary revival of the idea of civil society within academia and policy circles is a curious event. It appears to be correlated to the demise of the Soviet Union and the MARKET triumphalism that followed (see NEO-LIBERALISM). For advocates of economic GLOBALIZATION – an institutionalized project of market deregulation – the term ‘civil society’ functions as placeholder for an array of signifiers that are used almost interchangeably: private sphere, free market, free society, democracy, social capital and so on. In short, civil society denotes that desirable zone of activities and associations that is putatively free from state intervention.

Contrast this usage with that by communarians and left liberals, who worry about the expansion of administrative and economic mechanisms into virtually all spheres of life under late CAPITALISM. For them, the concept of ‘civil society’ represents a fading terrain of DEMOCRACY that must be preserved and resuscitated. Thus, civil society appears in their writings as the sphere of social interaction composed of ‘the intimate sphere (especially the family), the sphere of associations (especially voluntary associations), social movements, and forms of public communication’ (Cohen and Arato, 1992, p. ix). It is differentiated from both a political society of ‘parties, political organizations and political publics (in particular, parliaments)’ and an economic society ‘composed of organizations of production and distribution, usually firms, cooperatives, partnerships, and so on’ (ibid.).

**civilization** (1) A complex sociocultural formation. (2) An evolutionary process of cultural development, most often associated with the German sociologist Norbert Elias (1897–1990), who traced a ‘civilizing process’ in post-medieval Europe. The two have often been connected through the distortions of a colonialist imaginary that treats the ‘West’ as coterminous with ‘civilization’, divides the world into superiors and SUBALTERNS (often described as ‘barbarians’ or ‘savages’), and advances its own ‘civilizing mission’ to ‘enlighten’ or ‘develop’ them (cf. PRIMITIVISM). It is scarcely surprising to find that the term ‘civilization’ originated in Europe in the middle of the eighteenth century, when Europe was so busily encountering its ‘OTHERS’ (Mazlish, 2005). In the course of the twentieth century, anthropologists, archaeologists, ancient historians and other scholars recognized multiple civilizations, however, and increasingly treated civilizations as complex, adaptive SYSTEMS (Butzer, 1980). These more technical concepts were put to work in comparative HISTORICAL GEOGRAPHY: for example, in studies of URBAN ORIGINS it is common to distinguish the Harappan civilization in the Indus Valley or the Mayan civilization in Meso-America. But the older colonial distortions have also resurfaced through polemical arguments about a contemporary ‘clash of civilizations’.

The most detailed version of this thesis was proposed by American political scientist Samuel Huntington (1993, 1997; see also Kreutzmann, 1998). Huntington argued that questions of collective IDENTITY – ‘Who are we?’ and ‘Who are they?’ (cf. IMAGINATIVE GEOGRAPHY) – assumed a special force under the pressures of GLOBALIZATION. He saw these as intrinsically cultural questions, whose answers were almost invariably provided by RELIGION. Far from the secular world of MODERNITY carrying all before it Huntington believed that the world was witnessing a global religious revival. For this reason he used religion to identify seven or eight major civilizations and to explain the conflicts emerging on the ‘fault-lines’ between them. His thesis was a
generalization of a polemic by British Orientalist Bernard Lewis on ‘The roots of Muslim rage’ and had the same destination (see ORIENTALISM). ‘The overwhelming majority of fault-line conflicts,’ Huntington concluded, ‘have taken place along the boundary looping across Eurasia and Africa that separates Muslims from non-Muslims’. Huntington attributed this to what he called, with offensive disregard, ‘the Muslim propensity toward violent conflict’, and argued that since the Iranian revolution that toppled the Shah in 1979, a ‘quasi-war’ had been in progress between Islam and the West. Huntington’s ideas gained a new lease of life following 9/11 (Salter, 2002), but they have been sharply criticized both for their conceptual crudity – in particular, Huntington’s unsophisticated rendition of cultural interaction and identity formation (Said, 2000; Sen, 2006) – and for their unreflective demonization of Islam, or Islamophobia.

Kreutzmann (1998); Robertson (2006).

class In The communist manifesto (2002 [1848]), Karl Marx and Friedrich Engels asserted that ‘[t]he history of all hitherto existing society is the history of class struggles’. This declaration marks the foundations of class analysis. Although the concept of class has since come into wide usage, it remains contested. There is disagreement on how best to define it, on its general role in SOCIAL THEORY and on whether it remains relevant to the analysis of contemporary societies. For some, classes have become largely redundant in today’s societies; for others, class persists as one of the fundamental forms of social inequality and POWER. Some view class as a narrow economic phenomenon, while others embrace a more elastic conception that spans cultural dimensions and economic conditions. In its most persistent popular sense, class refers to a social division or system of rank order, evident in the phrase ‘upper, middle and lower classes’, that is associated with position, privilege and hereditary advantage (or the lack thereof). Class is also construed as distinctive bodily practices, such as attire, carriage, speech, diet, habitation and forms of lifestyle consumption – all linked to underlying unequal structures of material resources.

Uses of the term ‘class’ are always evaluative, whether positive or pejorative. Hence, the upper classes are sometimes the ‘aristocracy’ – endowed with a natural authority and disposition to rule – or else the ‘leisured class’ – parasitic on society’s surpluses and given to ostentatious consumption. Correspondingly, the middle classes are sometimes the ‘enterprising’ classes, who embody individual initiative, toil and prudence, and form the mainstay of civil society. Alternatively, they are the bourgeoisie – merchants, traders, entrepreneurs and professionals, committed to defending the inequalities and privileges of private property and to organizing the exploitation of the working classes. The lower classes are sometimes the ‘working classes’ or the ‘working poor’ – simple, hard-working and law-abiding people, who can claim no inherited privileges – or, alternatively, the ‘lower orders’ – uncivilized and unruly (and in some renderings, criminal and sexually promiscuous), who court idleness and are a drag on economic progress. The eventful ‘discovery’ of an UNDERCLASS by US-based conservative academics and commentators in the 1980s added a gendered and racial twist to these negative portraits. In this ‘culture of poverty’ discourse, which significantly influenced the 1990s policy shift in the US from welfare to workfare, the underclass came to signify a disaffected layer of work-shy, feckless, criminal, undeserving and semi-detached poor people, typically black and from disorganized households headed by single mothers, who had grown accustomed to surviving on excessively generous handouts from government-run welfare programmes.

From an academic standpoint, the analysis of class has taken two dominant forms, sorted by historical lineage. The first set of approaches, deriving from Karl Marx, pivots around the concepts of class relations and class structure (see MARXIST ECONOMICS). Other adjectival uses of the term class – class location, class conflict, class interests, class formation and class-consciousness – obtain their meanings from their link to class relations and class structure. Sociologist Erik Olin Wright contends that class relations should be viewed, sensu stricto, as a specific form of prevailing social relations of production (Wright, 2005). These, he says, designate the different kinds of rights and powers of persons in society who participate in production. When the rights and powers of people over productive RESOURCES are unequally distributed – when some people in a society have greater RIGHTS and powers with respect to certain productive resources than do others – these relations can be described as class relations (see CAPITALISM). It is important to note that the rights and
powers in question do not pertain to the ownership or control of things in general, but specifically to resources or assets as they are deployed in production. The fundamental contrast in capitalist societies, for example, is between owners of means of production (machines, inputs, space etc.) and owners of labour power, where each category of owner – the capitalist and the labourer – deploys the resource that they own in production. That said, it is worth emphasizing that class relations as defined are elastic enough to recognize patriarchy within the household and beyond and racial discrimination within society (see racism) as concurrent class processes. Meanwhile, work in radical geography has convincingly shown that exploitative class relations are fundamentally spatial and that this spatial organization is critical to understanding the nature of uneven development.

The ambiguity of class location – or location within social relations of production – is forcefully illustrated by managers within corporations, who exhibit the rights and powers of both capital (they can hire and fire workers, make decisions about new technologies and changes in the labour process, etc.) and labour (they cannot sell a factory, they have limited discretion in the use of surplus or profit, they can be fired from their jobs if the owners are unhappy, etc.). Workers as corporate shareholders (via an employee stock ownership plan, for example) provide another vivid illustration of ambiguity, since they simultaneously occupy two class locations. Other instances that complicate the empirical exercise of class location include persons who work at two jobs, one as a worker in a firm and the other as a self-employed tradesman; professional women, who employ a full-time housemaid; or historically, working-class sepoys stationed in colonies who, by virtue of racial difference, found themselves in positions of class superiority vis-à-vis natives (one imagines a similar phenomenon at work in today’s imperial outposts). In short, class relations, class structure and class location in societies are complex – as such, we should presuppose neither unity of purpose (class interest) nor consciousness (class agency) within a given class category (see Marx, 1963 [1852]).

The German sociologist Max Weber’s analysis of class is the primary alternative to Marxist class analysis. In Weber’s scheme, classes are distinguished by positions of relative advantage and disadvantage in terms of wealth and income. He writes: ‘We may speak of a “class” when (1) a number of people have in common a specific causal component of their life chances, in so far as (2) this component is represented exclusively by economic interests in the possession of goods and opportunities for income, and (3) is represented under the conditions of the commodity or labor markets’ (Weber 1968 [1946], p. 181).

While there are overlaps here with Marx’s understanding of class, there are also clear differences. Weber, for instance, emphasizes ‘personal life experiences’ and ‘life chances’ as critical aspects of ‘class situation’, and takes class to be ‘any group of people that is found in the same class situation’ (ibid.). Thus, whereas for Marx class is an objective set of social relations, for Weber subjective elements become key. Also in contrast to the Marxist view of class as relational, the Weberian view emphasizes class as market position. Classes are hierarchical arrangements, but potentially dynamic ones because market position may be changed by collective strategies in the labour market (e.g. through professional associations or trades unions). In underscoring the ‘life chances’ that accompany ‘class situation’, Weber draws attention to individuals’ prospective ‘personal life experiences’: ‘the probabilities of social and occupational mobility; of educational access and achievement; of illness and mortality’ (Clarke 2005, p. 40). While classes, in Weber’s view, derive unambiguously from economic interest, they are linked to political organization (party) and social position (status), both of which may be shaped by non-economic processes and may influence ‘class-consciousness’. The French sociologist Pierre Bourdieu is a prominent example of a scholar who has creatively fused the Marxist and Weberian perspectives of class in his analysis of various forms of capital.

**class interval** A key element in the design of a quantitative map that partitions the range of data values into discrete categories, each assigned a unique symbol. Common on choropleth maps, class intervals are also used for maps of linear and point phenomena and embedded in maps on which isolines divide the data into categories or layers. Typically, a map key links the class intervals to their respective symbols, which may vary in size, greyscale value or color. Because different class intervals can yield radically different depictions of the same data, viewers
should be wary of ill-informed, careless or biased map authors (Evans, 1977; Monmonier, 2005).

**classification and regionalization** Procedures – most of them quantitative – for grouping individuals into categories. *Classification* involves splitting a population into mutually exclusive categories on pre-determined criteria, either deductively (using a previously determined set of classes, such as town size-groups) or inductively (finding the best set of classes, on pre-determined criteria, for the data set being analysed: cf. DEDUCTION; INDUCTION). Some procedures start with the entire population and divide it; others start with individuals and group them into classes. Most proceed hierarchically, generating classes that nest within each other at various scales. The goal is to produce classes whose members are more like other members of their class than they are members of other classes: classes are internally homogeneous and externally heterogeneous. A range of classification algorithms is available in standard statistical packages.

*Regionalization* (cf. REGION; REGIONAL GEOGRAPHY) is a special case of classification in which the individuals classified are spatially defined units (usually areas) and the resulting classes (regions) must form contiguous spatial units. Because of this constraint, regions may not be as internally homogeneous as would be classes generated for the same set of areas but without the insistence on contiguity. These latter form regional types, areal units grouped without a contiguity constraint, so that similar areas may be spatially discontinuous (e.g. areas with Mediterranean climates).

Recent work has argued that classifications should not impose firm boundaries, and suggested instead the use of *fuzzy sets* to indicate the probability that an individual belongs to any particular class. (See also DISTRICTING ALGORITHM; GEODEMOGRAPHICS; MODIFIABLE AREAL UNIT PROBLEM; REDISTRICTING.)

**climate** Conventionally understood to comprise the meteorological elements – rainfall, wind, temperature, insolation, humidity and so on – which characterize the general atmosphere over a zone of the Earth’s surface for a period of time. The Intergovernmental Panel on Climate Change (IPCC) (2003) thus identifies climate, in its Glossary of terms, as ‘average weather’ or ‘more rigorously as the statistical description of the mean and variability of relevant quantities over a period of time ranging from months to thousands or millions of years’. To this, the IPCC glossary adds that the World Meteorological Organization specifies 30 years as the ‘classical’ temporal period for determining average conditions. The crisp clarity of this definition, however, masks the concept’s contested historical lineage. During the period of the European ENLIGHTENMENT, for example, Diderot and d’Alembert’s celebrated *Encyclopédie* identified as one of its definitions of climate a REGION with characteristic seasons, soils and cultural mores (Feldman, 1990). The Victorian geologist Samuel Haughton (1880, p. 74) similarly typified climate as the ‘complex effect of external relations of heat and moisture upon the life of plants and ANIMALS’, including the human species. Given these associations, it is not surprising that the study of climate has routinely embraced matters of social, moral and political concern.

**HUMAN GEOGRAPHY**’s engagements with climate have thus been manifold. Among the most conspicuous have been a noticeable inclination amongst its advocates to reduce ENVIRONMENTAL DETERMINISM to climatic determinism; the incorporation of climatic conditions into studies of the perception of ENVIRONMENTAL HAZARD and RISK; discussion about the role of human agents in inducing climate change and GLOBAL WARMING; medical geography’s earlier interest in the role of climate-correlated pathologies; and imperial debates about human capacities to adapt to different climatic regimes. Each of these domains has witnessed controversy. Amongst early-twentieth-century environmental determinists, for example, climate was often called upon to justify various racial ideologies that attributed excellence to the temperate zones and explained the historical trajectory of civilization in the vocabulary of climatic circumstance (Livingstone, 1994: see also RACE). Controversy has also attended proposals over the steps that need to be taken to curb the influence that human society has had in climate change and over the degree to which the Earth’s planetary atmosphere can be understood as a self-regulating system: this has immediate political implications, since individual states have been reluctant to bear the political consequences of prioritizing environmental restraint over economic growth.
Amongst early medical geographers, debates about climate revolved around whether disease should be understood in miasmic–ecological terms or in the language of the new germ theory (Rupke, 2000: see also MEDICAL GEOGRAPHY). Debate raged too amongst colonists over whether human acclimatization was possible and, if so, under what conditions it could be effected.

Other human dimensions of climatic discourse and practice have also recently been the subject of geographical investigation. The realization that climate has often been conceived of in moral categories has established it as a significant component in a range of MORAL GEOGRAPHIES. Thus historians of SCIENCE, for example, have demonstrated how the study of meteorological conditions was rooted in a suite of discourses about the prediction of ominous social and political happenings (Jankovic, 2000). The ways in which climate was used to pathologize whole zones of the GLOBE by resorting to it as the explanation for debility as well as parasitic fecundity have also been exposed (Naraindas, 1996). At the same time, enquiries within historical geography have revealed how climate was culturally constructed to serve various, often racial, interests among philosophers, geographers, medical practitioners, travel writers and artists (Livingstone, 2002a). These pronouncements contributed directly to the production of the idea of TROPICALITY by castigating the tropical world as medically and morally degraded, and by providing a naturalistic justification for various labour practices in the colonial world and IMMIGRATION policies in the West. Read in this register, climate has persistently surfaced as a cultural category that has been deployed as a HERMENEUTIC resource to advance moral, political and social interests.

The practices of meteorological instrumentation have also raised significant geographical questions. Weather conditions are derived from a variety of instrumental devices, such as anemometers, hygrometers, thermometers, barometers and pluviometers (see SCIENTIFIC INSTRUMENTATION). At centres of calculation, such as the Meteorological Office, the aggregate mensural yield of widespread meteorological networks is assembled as affiliated observation stations return standardized records to weather information centres. As Anderson (2005a, p. 290) puts it: ‘Philosophically, the science of meteorology was global; in practice, global science developed in distinctively different political and geographical landscapes, and contemporaries insisted on the importance of the differences.’ The inherently geographical nature of this process of knowledge production as information moves from specific sites into general circulation has been the subject of interrogation by both historians and geographers, who have examined this scientific impulse to escape the bounds of the local (Jankovic, 2000; Naylor, 2006). The significance of missionaries in the gathering of climatological data has also attracted scrutiny, as their records provide information on the weather history of locations in which they worked (Endfield and Nash, 2002). Such work has drawn attention to issues congregating around the standardization of measurement practices, the social geography of who can be trusted to deliver reliable climatic information, the regulation and management of distant observers, and the cultural politics of shifting boundary lines between amateur and professional.

Matters of climate are thus profoundly implicated in a range of discourses. The racial politics of climatic determinists, the apocalyptic tincture of certain strands of climatic prophecy, the economic geography of weather-related insurance, and the social constitution of climatological knowledge are just a few of the ways in which climate is clearly disclosed as a cultural construct.

Jankovic (2000); Livingstone (2002a).

Clusters A concept usually associated with the work of Michael Porter, from Harvard Business School’s Institute for Strategy and Competitiveness. Porter defines clusters as ‘... geographic concentrations of interconnected companies, specialized suppliers, firms in related industries, and associated institutions (for example universities, standards agencies, and trade associations) in particular fields that compete but also cooperate’ (Porter, 1998c, pp. 197–8). According to Porter's work, within a cluster: (1) information flows increase between related and supporting industries; (2) market awareness of firms improves thanks to the concentration in the cluster of demanding clients; (3) peer pressure/competition drives INNOVATION as rivals seek to out-compete one another; and (4) local ‘factor conditions’, such as the availability of skilled labour in a particular area, are exploited to make firms globally competitive. These four forces form part of Porter’s ‘diamond model’ for successful clusters. In addition, as Porter also points out, the social foundations of a cluster are vital because
success is reliant on ‘... social glue that binds clusters together, contributing to the value creation process. Many of the competitive advantages of clusters depend on the free flow of information, the discovery of value-adding exchanges or transactions, the willingness to align agendas and to work across organisations, the strong motivation for improvement. Relationships, networks, and a sense of common interest undergird these circumstances’ (Porter, 1998c, p. 225).

The concept of the cluster mirrors in many ways ideas contained in a wider set of literatures. Dating back to Marshall’s (1890) work on INDUSTRIAL DISTRICTS and, more recently, through studies of what have been called LEARNING REGIONS and innovative milieux (Asheim, 1996; Malmberg and Maskell, 2002), emphasis has been placed on the importance of geographically distinctive arrangements of firms in one industry for knowledge production and circulation. This has become especially important in light of recent debates about the KNOWLEDGE ECONOMY and the need for cities and regions to be globally competitive centres of INNOVATION. It is Porter’s cluster concept that has gained most traction in policy circles, with regional authorities throughout the world employing Porter and his followers to develop a cluster strategy for their local industries. Many are, however, critical of this approach. For geographers, the main concern with the cluster concept has been its apparent geographical fuzziness and the way in which the boundaries of a cluster are never defined in existing work. In addition, the way in which iconic spaces such as Silicon Valley are used to produce ‘elastic’ theoretical models that can be turned into fashionable development concepts has also caused concern, particularly because of the questionable levels of success of such models (see Martin and Sunley, 2003). co-evolution In biology and ECOLOGY, co-evolution refers to the reciprocal changes that occur between populations of species as they interact. In one sense all evolution is co-evolution, as all species are considered to affect and be affected by changes to other species and their environments. In more specific terms, co-evolution is understood to apply to those interactions where there has been mutual, symbiotic or parasitic changes that have affected both parties that are temporally and spatially proximate. In HUMAN GEOGRAPHY and the social sciences, the term has been used loosely to understand the complex relationships between, for example, technology and place (Graham, 1998), economy and environment (Costanza, 2003) and humans and companion species (Haraway, 2003). The shared aim is to avoid reductionism and determinism, and point to the relational character of change. SJH

cofabrication An orientation towards research and intervention emphasizing the ontological and political requirement of ‘working together’ (Whatmore, 2003). Derived from the work of the philosopher Isabelle Stengers (1997), the implications and practices involved in co-fabrication have best been exemplified in SCIENCE and technology studies and ACTOR-NETWORK THEORY, where the production of reality is demonstrated to be something other than a zero-sum game. Rejecting discourses of either pure human invention or discovery of already existing reality, co-fabrication enacts a relational understanding of ONTOLOGY, suggesting that the more activity there is from a researcher, the more – if they are to be successful – activity there is from the researched (Latour, 1999c). This maxim applies as much to human-microbe ASSEMBLAGES in the laboratory as it does to studies of, or with, social groups. In terms of the latter, co-fabrication leads to something akin to ACTION RESEARCH, though with the added implication that all participants in the research process are treated less as informants and more as colleagues (Stengers, 1997). For social science, this requires a change of stance, away from distanced, expert critique and towards the crafting of co-operative ventures. SJH

cohort A group of people with a common demographic vintage. Cohorts are most often defined on the basis of being born in the same year or years (i.e. birth cohorts, such as the US ‘baby boom’ born in the US between 1946 and 1964), although marriage, divorce, MIGRATION and graduation events also define groups whose life experiences and biographies can be analysed over time. Adopting a cohort approach has deepened understanding of very low levels of FERTILITY (Leshtega and Willems, 1999) and spatial variations in MIGRATION (Plane, 1992), and supplements period approaches that analyse changes occurring between two points in time. AJB
Cold War  

The period of international diplomatic, political and military rivalry between the United States of America (USA) and the Union of Soviet Socialist Republics (USSR), conventionally understood as lasting from the end of the Second World War in 1945 to the fall of the Berlin Wall in 1989. As with other periods of international transformation, the Cold War is subject to a variety of different interpretations, each highlighting different causes.

The conventional historiography of the Cold War understands the period as one of realist geopolitics, in which the balance of power and spheres of influence were historical necessities (Halle, 1991). Although allies during the defeat of Nazi Germany, the USA and the USSR approached the postwar order with different visions, the USA backing a market-oriented liberal order (see capitalism; democracy), while the USSR sought friendly regimes on its borders and the spread of communism internationally. At the 1945 Yalta summit, President Roosevelt, General Secretary Stalin and Prime Minister Churchill outlined plans for zones of military occupation in defeated Germany, with the liberated territories to be democratic. But with Soviet forces occupying the east and the allies dominant in the west, Europe was divided by what Churchill called an ‘Iron Curtain’. This produced two competing military alliances – the North Atlantic Treaty Organization (NATO, est. 1949) organized by the USA in the west, and the Warsaw Pact (est. 1955), dominated by the Soviets in the east, with the former seeking to contain or roll back the latter.

These ‘ideological blocs’ (see ideology) became the basis for the organization of international politics for more than 40 years, with their enmity symbolized by the nuclear arms race and materialized in a number of global events, including the building of the Berlin Wall in 1961 and the Cuban Missile Crisis of 1962, amongst many others. Although many flashpoints were in Europe, the Cold War was a global geopolitical formation that produced the ‘third world’ as a non-aligned group of states that declined to side with either the ‘First World’ (the USA and its allies) or the ‘Second World’ (the USSR and its allies). Although the Cold War did not erupt into direct ‘hot’ war between the two superpowers, there were numerous proxy conflicts between their allies, largely in Africa and Asia, often piggybacking on indigenous struggles, in which millions perished. The enmity between the blocs was eased by diplomacy, especially the period of ‘detente’ in the 1970s, and ended by the early 1990s when a variety of forces intersected to remove the Soviet hold over eastern Europe and the eventual demise of the USSR as a superpower.

Revisionist accounts of the Cold War have detailed the economic forces driving American expansionism, with the conflictual imagi-native geographies of capitalism and communism having existed prior to the geopolitics of the post-Second World War era. Perspectives from critical geopolitics (e.g. Campbell, 1998; Glassman, 2005) argue that the Cold War was a discursive formation as much as a geopolitical condition. This ‘architecture of enmity’ (Shapiro, 1997) materialized political identities that have survived the demise of the Soviet Union and helped constitute new enemies.

collective consumption  

Basic public services such as schools, health services and utilities, usually provided by the state, which facilitate or enable the reproduction of labour power (Castells, 1977) (see social reproduction). The notion of collective consumption developed within Marxist urban theory, with the spheres of production (of goods and services) and labour reproduction as defining elements (Pinch, 1989). It is an effort, therefore, to theorize social relations in capitalist space; specifically, the means by which labour is reproduced ‘on a daily and intergenerational basis’ (Pinch, 1989, p. 47). Castells (1977) identified collective consumption as the basis for a framework for the analysis of labour reproduction in a specific sphere of social and spatial life, that of the urban (Saunders, 1986, p. 172). According to Castells’ (1977) framework, since housing, recreational and health facilities, for example, are provided to people in specific locations on the basis of their collective use, investigation of collective consumption constitutes a fixed territorial setting for empirical analysis (Saunders, 1986). Thus, Castells (1977) argued that he had identified a specifically urban space with the specification of the labour reproductive and collective consumption processes. However, these processes do not occur exclusively in urban places, and the challenges of reproduction and collective consumption are also evident.

Weeks (1999, Chs 5 and 8).
in rural areas or small towns (Saunders, 1986).

Castells refined his approach to collective consumption in his influential *The city and the grassroots* (1983). In it, he argued that the increasing role of the state in collective consumption, as part of efforts to resolve the contradictions of capitalism, did not solve those contradictions but, instead, led to an increasingly contentious and political consumptive sphere (Castells, 1983; Saunders, 1986). The result is collective activism: urban social movements organized against or as a challenge to the state over its management of and provisions for collective consumption.

Pinch (1989) argued that, with the state posited as the provider of goods and services for collective consumption, the concept is too narrow, since many collective goods can be privately provided. Indeed, with increasingly neo-liberal states, collective consumption seems an outdated concept. The problem and question of the reproduction of labour – such as how to provide for childcare or health services – however, remains salient (Pinch, 1989).

Contemporary scholars concerned with these issues focus less on the state and more on its role as one element in public–private partnerships, and the responses in and effects on various communities (see community).

Castells (1983); Herbert (2005).

**Collinearity** A statistical problem associated with the general linear model, especially multiple regression analysis. If two or more of the independent variables are substantially correlated, the resulting regression coefficients will provide unreliable statements of the true relationships and be difficult to interpret. Statistical tests can identify the extent and impact of collinearity in an analysis.

**Colonialism** An enduring relationship of domination and mode of dispossession, usually (or at least initially) between an indigenous (or enslaved) majority and a minority of interlopers (colonizers), who are convinced of their own superiority, pursue their own interests, and exercise power through a mixture of coercion, persuasion, conflict and collaboration (cf. Osterhammel, 1997, pp. 14–20). The term both denotes this relationship and serves as an interpretation of it – customarily one in which the experiences of colonizers and the colonized are at odds. Derived from the Latin word ‘colonia’ (estate, distant settlement), and typically promulgated within the framework of an empire, ‘colonialism’ was first used as a term of disapprobation in eighteenth-century debates about the morality of slavery, and has since been conceptualized as a distinctly Western modality of power that has been closely connected to the evolution of capitalism, modernity and eurocentrism.

(1) **Concept and imagery.** Colonialism is commonly viewed as the chief variant and consequence of imperialism: the tangible means by which disparate parts of the world became subordinated to the drives and dictates of a separate and distant imperial centre (metropole or mother country), and struggles over territory, resources, markets and national prestige became displaced overseas (cf. world-systems theory). The term ‘colonization’ denotes the array of expansionist projects – exploration, war, geopolitical rivalry, military conquest and occupation, commerce, migration, settlement, state formation and cultural representation – from which particular colonialisms arise.

A common – and not inaccurate – image of colonialism is of a state-centred system of power characterized by brute exploitation, astonishing cultural arrogance and racism, which reached its heyday in the early twentieth century, when European colonial empires spanned the globe (the British Empire covering 20 per cent of the world’s land surface), and colonial rule (then justified as a ‘civilizing mission’) seemed secure to its protagonists, in spite of widespread anti-colonial resistance. Colonialism has also been viewed as symptomatic of an epistemological malaise at the heart of Western modernity – a propensity to monopolize and dictate understanding of what counts as right, normal and true, and denigrate and quash other ways of knowing and living. Yet it is more than just a will to exercise dominant control, or a proprietary project that constructs the world as the West’s bequest – although it is surely both of these things. Nor has it simply been a hierarchical and diffusionist process, solidified in a core–periphery relationship, which spawned what Frantz Fanon (1963 [1961], pp. 37–8) described as ‘a world cut in two’ and a colonial world ‘divided into compartments’ – with the colonized enjoined to emulate the West. Colonialism has also been characterized by subversion and, some argue, by inherent flux and contradiction, ambivalence and hybridity. Not feeling at home in empire was a visceral experience for the colonizer the world over.
It has become commonplace to observe that colonialism involves a mutual interdependence of forms, at root because colonial identities are constructed in relation to both a metropolitan core and indigenous/colonized lands and peoples. Identities are formed and stretched across both metropolitan colonial and colonizer/colonized divides, creating what Edward Said (1993, pp. 3–61) – a key thinker and influence on geographers – dubs ‘overlapping territories’ and ‘intertwined histories’. The interdisciplinary critical project of POST-COLONIALISM, which is inspired, in part, by a ‘desire to speak to the Western paradigm of knowledge in the voice of otherness’, has sought to show that Western/metropolitan SUBJECTIVITY has not been constituted in a self-contained box, but through this long, stretched and often violent process of colonial exchange, and tries to expose and destabilize the way in which Western and non-Western, and colonial and post-colonial, identities have been shaped by potent binaries – of ‘CIVILIZATION’ and ‘savage’, ‘modernity’ and ‘tradition’ and so on (Goldberg and Quayson, 2002, p. xiii).

This critical reconfiguration of Western history and CULTURE is intrinsically linked to what many see as the cornerstone of colonialism’s SPATIALITY: the importance of displacement for both colonizer and colonized (and for both their knowledge systems and ways of life), and the subsequent difficulty of ever going back to some pristine or authentic connection between PLACE and IDENTITY that is uncontaminated by the experience of colonization. ‘Just as none of us is outside or beyond geography,’ Said (1993, p. 7) writes in an influential passage, ‘none of is completely free from the struggle over geography. That struggle is complex and interesting because it is not only about soldiers and cannons but also about forms, about images and imaginings’. Colonialism can be distinguished from IMPERIALISM in terms of the local intensity and materiality of this geographical struggle, centrally over home and territory. Said spurred interest in how colonialism works as a cultural discourse of domination animated by images, narratives and representations – and mediated by CLASS, RACE, GENDER, SEXUALITY, NATION and RELIGION – as well as a material project and feat of power. Over the past twenty years, colonialism has been studied as a ‘cultural technology of rule’ imperilled by various ‘investigative modalities’ (Cohn, 1996).

Said (1978, pp. 49–73, 327) deploys the term IMAGINATIVE GEOGRAPHY to capture the connective imperative between geography and DISCOURSE within the unequal framework of empire: the ‘dramatisation’ of difference between ‘us’ and ‘them’, and ‘here’ and ‘there’, with texts ‘creat[ing] not only knowledge but also the very reality they appear to describe’. In famously showing how the Orient was produced, its meaning regulated and Western dominance over it shaped, by Western knowledge, institutions and scholarship (by a discourse of Orientalism), Said does not collapse the distinction between representation and reality. Rather, he underscores how ORIENTALISM and other colonial discourses exert authority by creating asymmetrical relationships between Western and ‘other’ knowledge systems. It is through this process of ‘knowledgeable manipulation’ that distorted images and stereotypes of foreign lands and peoples become taken-for-granted, traits of difference become ascribed to particular spaces, places, environments and natures, and ‘other’ peoples are deemed unable to represent or govern themselves. This is what Said (1978, p. 63) means when he describes ‘the Orient’ as an ‘enclosed space’ and a ‘stage affixed to Europe’, and David Arnold (2005, p. 225) when he describes how British observers ‘affixed’ India to alien European ideas of landscape and nature – as part of the Tropics (see TROPICALITY). While Said has been criticized for obscuring how non-Western peoples responded to this epistemological onslaught, he revealed how colonialism revolves around grammars of difference, othering and exclusion that are acutely spatial – that function as ‘trait geographies’ (Gregory, 2001b).

(2) History and interpretation. As much of the above implies, there is more than one MODEL of colonialism. Indeed, it is important to recognize how different meanings and models of colonialism have evolved and operate a posteriore. Important distinctions have been drawn between different types of colonies: exploitation colonies (e.g. British India, French Indochina; slave colonies, ‘protectorates’ and ‘dependencies’), which were established primarily for the purpose of capitalist economic extraction, where tiny expatriate colonial elites often governed large subject populations, and ideologies of RACE and paternalism played a pivotal role in colonial rule; settler colonies (e.g. North America and AUSTRALASIA), whose political economies were premised on the availability of extensive tracts of cultivable and resource-rich land, and where indigenous peoples were systematically displaced by
colonists and native populations plummeted due to disease; and maritime enclaves (e.g. Aden, Hong Kong, Jakarta and Malacca), which served as commercial and military nodes in encompassing imperial networks. While these are ideal types – for instance, French Algeria and Spanish Peru were both extraction and settler colonies – a large literature identifies the distinct power relations pertaining to these different colonial formations. The close association of colonialism with European/white minority rule has meant that the term has been deemed inapplicable to some situations – until recently, the colonial period of US history, where colonists along the Atlantic seaboard soon outnumbered native people. And the ‘salt water’ association between colonialism and distant overseas possession explains why expressions such as ‘internal colonialism’ have been used to describe situations in which colonialist relationships exist within the borders of, or contiguous to, an imperial state or kingdom (e.g. between England and its ‘Celtic fringe’, especially Ireland).

The history of colonialism has also been divided into distinct periods: Spain and Portugal’s initial sixteenth-century conquest of the New World; the seventeenth-century creation of an ‘Atlantic world’ revolving around the circulation of people and commodities, and centred on slavery and the racialized plantation economies of the Caribbean; the eighteenth-century extension of European (especially British and Dutch) trade and domination in Asia; the nineteenth-century building of European land empires in Africa and Asia and the emergence of the USA as a significant player in the making of the world; the maturation of colonial export economies between 1900 and 1945; and a postwar welfare-minded colonialism that became entangled with independence struggles and decolonization.

Since the 1980s work on colonialism – much of which is either aligned with, or sees itself as a response to, post-colonialism – stems from the recognition that the postwar break-up of Europe’s colonial empires did not quickly or necessarily put once colonized regions on a par with the West – at any level. In 1965, Kwame Nkrumah coined the term neo-colonialism to describe how the West (and especially the USA) was perpetuating colonialism while upholding ideals of independence and liberty, the contradiction being as apparent in development models, which were the vehicles of a new cultural imperialism, as it was blatant in new international investment and trade relations (Young, 2001, pp. 44–56; cf. Development Geography; Third World; Transnational Corporation).

Some remarkable theoretical treatments of colonialism from this era – for example, the work of Fanon and Aimé Césaire – alight on the enduring and nefarious psychological influence of colonial categories of thought and social pathologies on post-independence politics and nationalism. And if, as this suggests, the colonial past was not over, then Derek Gregory (2004b, pp. 6, 117), adds what now seems an obvious rider: that the colonial past ‘is not even past’. Empire is being revived through the creation of new ‘colonizing geographies’ of division, partition and enmity (the war-torn Middle East currently bearing the brunt of them) that displays many affinities with past colonial ideas and practices. The United Nations has declared the period 2001–10 the ‘Second International Decade for the Eradication of Colonialism’.

Indeed, there is now arguably a greater range of opinion about colonialism than there has been for 50 years, including burly affirmations of its supposed benefits that feed on imperial nostalgia. On the other hand, there has been a radical re-reading of the West’s conception of its cultural evolution, and much academic soul searching, not least within European and North American geography, which has strong ties with empire, blasting apart disciplinary allegories of objectivity, progress and self-contained development (cf. Geography, History). Many discourses and practices that have been deemed central to geography’s make-up and heritage – exploration, mapping, surveying, Environmental Determinism, geopolitical model-building and latterly GIS – have been pressed into (and are still designed for) imperial service.

Cartography has been a colonizing tool par excellence. Maps brought ‘undiscovered’ lands into spatial existence, emptying them of prior (indigenous) meanings and refilling them with Western place-names and borders, priming ‘virgin’ (putatively empty land, ‘wilderness’) for colonization (thus sexualizing colonial landscapes as domains of male penetration), reconfiguring alien space as absolute, quantifiable and separable (as property), drawing mapped space into the unifying framework of Western knowledge and reason, and, along with the clock and calendar, effecting a fundamental reorganization (standardization) of the relations between time and space (Edney, 1997; cf. Time-Space Distanciation). Little wonder, then, that concepts and metaphors
of mapping and location have a seminal place in post-colonial theory.

(3) Critical problematics. While recent work on colonialism eludes simple characterization, it can usefully be located within a series of interrelated spatial poles of interpretation, which grapple with whether colonialism, in extremis, can and should be treated as uniform or diverse, coherent or fragmentary, centred or decentralised, and whether it put in train a cultural history of affinity or difference, connection or separation, inclusion or exclusion. These analytics can be traced through two pairs of watchwords that infuse work in the field of colonial studies and the wider project of post-colonialism.

With regard to diversity and specificity, recognition of the historical-geographical diversity of colonialism is often registered as a warning about the perils of generalizing about ‘it’ from particular locations (Algeria, India and the Caribbean being the crucibles of much theorizing). Colonialism is conceived as less amenable to abstraction than imperialism, as more localized and differentiated than models suggest, and in need of more comparative research. This critical impulse to extend what Fanon (1963 [1961], p. 239) called ‘the will to particularity’ – to expose the duplicity of Western universals and absolutes – has been manifested in calls to bring metropole and colony into ‘a unitary analytical field’ (Cooper and Stoler, 1997a, p. 1), to conceptualize colonialism as a ‘forged concept’ involving both similitude and difference (Lloyd, 1999, p. 7), and to re-examine those processes (both violent and intimate) that colonizers and the colonized shared, as well as those that set them apart.

A range of recent scholarship on struggles over ‘who was inside and who was outside the nation or colony, who were subjects and who were citizens’, demonstrates the importance of escaping older scholarly containers and ‘mapping . . . difference across nation and empire’ (Hall, 2002a, p. 20; Lambert and Lester, 2006). Starting from an analytical standpoint of liminality (how colonialism operates in terms of what it excludes and places outside its domain of comprehension and action), and from the premise that significant gaps existed between metropolitan/imperial prescriptions of power and the daily realities and pressures of colonial rule, a feminist-inspired literature examines how colonialism involves incessant struggles over the making and protection of cultural boundaries and frontiers – struggles that are gendered, sexualized and racialized, and that work to demarcate the foreign from the domestic, the civilized from the wild or savage and home from away (Stoler, 2002; Blunt, 2005).

Emphasis is now routinely placed on the spatiality of such struggles and dynamics, and geographers have been particularly concerned with how colonialism operates through: (i) particular sites and contact zones, such as ships, forts, plantations, trade posts, ports and cities, native reserves, mission stations, museums and exhibitions; (ii) the networks and institutions – such as the London-based Royal Geographical Society and Seville-based Council of the Indies – that coordinated the flows of people, goods, orders and information connecting this array of places and spaces; and (iii) the inscription devices and systems of representation – forms of recording, writing, and calculating distance and measuring difference, such as maps, journals, ledgers, paintings and despatches; practices of exploration, observation, fieldwork, classification and synthesis; and discourses justifying colonialism – that both shaped and were shaped by such sites, domains and networks (Driver, 2001a; cf. Centre of Calculation; Climate; Tropicality). This body of work emphasizes that Europeans’ ability to know, physically reach and govern distant and far-flung lands was something made, practiced and performed (and thus amenable to criticism and re-invention) rather than given (and was not some innate and distinguishing European quality and mark of its superiority).

However, such site-specific and de-centred readings can arguably lose sight of colonialism’s trans-historical traits and general effects – such as (for some) its propensity to racialize difference the world over, and (for others) the way in which the state is deemed to be the bearer of the most rational and civilized practices of rule – and thus undermine an anti-colonial politics that is responsive to the commonalities of experience among the colonized. Anti-essentialist and non-teleological approaches to colonial history that refuse to generalize and conceptualize colonialism in extremis, or as a totality, can trivialize its impact, and can serve divisive ethnic and nationalist agendas in the post-colonial world that ‘repeat . . . colonialism’s own strategy . . . to regionalize, split up, divide and rule’ (Young, 2001, p. 18). Conceptual and ethical tensions also arise when critical affiliation with the colonized (and other so-called ‘injured identities’) is derived from a critical stance that
underscores colonialism’s inherently fragmentary character, and sees both colonialism’s civilizing mission and ‘THIRD WORLD’ NATIONALISMS and revolutionary movements as doomed to failure and self-interest. One the other hand, geographers operating at the former margins of empire complain about the metro-centric focus of both older imperial histories, and newer critical accounts of the colonizing impact that metropolitan-based initiatives (such as cartography and travel) had on outlying regions. Viewing the colonized world from the (former) imperial centre – which is where a good deal of critical work on geography and empire emanates from – can blunt understanding of the specific and changing composition of colonial power in particular localities (Harris, 2004).

With regard to discursivity and dislocation, geographers have considered how a wide range of spatial practices and representations of space work as colonizing discourses – as textual and visual ‘scriptings’ and ‘spaces of constructed visibility’ that have shaped what Europeans understood to be ‘out there’ and framed how interaction was to proceed and be recorded (Duncan and Gregory, 1999). In prosecuting such ideas – TRAVEL WRITING being a prime focus – geographers have been critical of the reduction of colonialism to issues of discourse and representation, and a concomitant erasure of historical–geographical specificity, which has characterized much (especially literary) work in this area, and have coined expressions such as ‘spaces of knowledge’ and ‘geographies of truth and trust’ to underscore the materiality of discourse and the situated and embodied nature of colonial knowledge and power (Gregory, 2001b). Nevertheless, much of this literature has been preoccupied with the agency and texts of European/Western/colonizing projects and actors, and either overlooks native agency or subordinates indigenous knowledge to the gaze of the Western/metropolitan/post-colonial critic by representing it as the background noise against which the colonizing West stakes its claims to truth and power. While the difficulties involved in bringing native agendas and ‘other’ voices back into the colonial spotlight should not be underestimated, work that aims – laudably – to expose and question previously undisclosed connections between discourse and domination runs the risk of reinforcing the ideas, images and categories (of, for example, exoticism, primitivism and race) that it sets out to challenge. It does so, in part, Nicholas Thomas (1993) has pointed out, by obfuscating how colonial encounters operate as two-way and intersubjective (albeit still unequal) processes rather than as a one-way projection of desire and fear, or as a unitary imposition of power (see also TRANSCULTURATION).

All of this helps to dispel the illusion of a seamless or ineluctable process of Western expansion, and makes the current promulgation of a ‘post-colonial geography’ that seeks to assess what about geography (as a discipline, discourse and practice of power) might need decolonizing more than a belated or ironic gesture, as some have suggested. DCL

command economy An economy in which the means of production are owned and controlled by the state and in which central planning prevails. The term is used to distinguish economies, such as those in Eastern Europe until the early 1990s, from either capitalism or a mixed economy. The dismantling of command economies in Eastern Europe reflected an inability to produce goods in the quantities that people had come to expect, as a result of difficulties of coordination and the lack of efficiency incentives. However, the economies that replaced them have their own imperfections, including large-scale criminalization, reflecting the difficulty of creating market-regulated economies in former socialist states (cf. SOCIALISM). DMS

commercial geography A forerunner of ECONOMIC GEOGRAPHY concerned with describing, tabulating and cartographically representing the geographical facts of commerce for practical, business ends. Coined by the philosopher Immanuel Kant (1724–1804) in the late eighteenth century as one of his six divisions of GEOGRAPHY, commercial geography was systematically taken up by German geographers from the middle of the nineteenth century. In Britain, the Scottish geographer George Chisholm (1850–1930) provided the first English-language version of the project in his 1889 tome, A handbook of commercial geography, and identified three sections: how commodities are produced, what commodities are produced and where commodities are produced. Chisholm provided no indication of the complexity of the concept of COMMODITY, however, and seven years before his book was published the German geographer Götz
had already recognised a new sub-discipline, economic geography, that was to be a science rather than an encyclopaedia of facts for improving the bottom line (Sapper, 1931, p. 627).

**commodity** With its price tag, said the great German critic Walter Benjamin, the commodity enters the market. The *Oxford English Dictionary* defines a commodity as something *useful* that can be turned to *commercial advantage* (significantly, its Middle English origins invoke *profit*, *property* and *income*); it is an article of *trade* or *commerce*, a thing that is expedient or convenient. A commodity, in other words, is self-evident, ubiquitous and everyday; it is something that we take for granted. Marx (1967 [1867]) said that commodities were trivial things but also bewildering, ‘full of metaphysical subtleties and theological capers’.

Commodities are everywhere, and in part define who and what we are. It is as if our entire cosmos, the way we experience and understand our realities and lived existence in the world, is mediated through the base realities of sale and purchase. Virtually *everything* in modern society is a commodity: books, babies (is not adoption now a form of negotiated purchase?), debt, sperm, ideas (intellectual property), pollution, a visit to a national park and human organs are all commodities. Even things that do not exist as such appear as commodities. For example, I can buy a ‘future’ on a basket of major European currencies, which reflects the average price (the exchange rate) of those national monies at some distant point in time. Other commodities do not exist in another sense; they are illegal or ‘black’ (heroin, stolen organs). Others are fictional (e.g. money scams and fraud). Visible or invisible, legal or illegal, real or fictive, commodities saturate our universe.

Commodity-producing societies – in which the dominating principle is commodities producing commodities – are a quite recent invention, and many parts of the world, while they may produce for the market, are not commodity societies. Socialist societies (and perhaps parts of China and Cuba today) stood in a quite different relationship to the commodity than so-called advanced capitalist states (cf. *socialism*). Low-income countries, or the *third world* so-called, are ‘less developed’ precisely because they are not mature commodity-producing economies (their markets are undeveloped or incomplete, as economists might put it) – they are not fully *commoditized*.

So the full commodity form as a way of organizing social life has little historical depth: it appeared in the West within the past 200 years. And over large parts of the Earth’s surface the process of *commodification* – of ever greater realms of social and economic life being mediated through the market as a commodity – is far from complete. Perhaps there are parts of our existence, even in the heart of *modernity*, that never will take a commodity form.

A peculiarity of a commodity economy is that some items are traded as commodities but are not intentionally produced as commodities. Cars and shoes are produced to be sold on the market. But labour – or, more properly, labour power – is also sold and yet it (which is to say me as a person) was not conceived with the intention of being sold. This curious aspect of labour as a commodity under capitalism is as much the case for land or Nature. These sorts of curiosities are what Karl Polanyi, in his book *The great transformation* (2001 [1944]), called ‘*fictitious commodities*’. Polanyi was of the opinion that market societies that do not regulate the processes by which these fictitious commodities become commodities will assuredly tear themselves apart. The unregulated, free-market, commodity society would eat into the very fabric that sustains it by destroying *nature* and by tearing asunder the most basic social relationships (see *capitalism*).

The commodity raises the tricky matter of price, which after all is the *meaning* of the commodity in the capitalist marketplace: how it is fixed, and what stems from this price fixing. For example, the running shoes that a poor inner-city kid in the USA yearns for are Air Nike, which cost slightly more than the Ethiopian GNP per capita and perhaps more than his mother’s weekly income. Or consider the fact that a great work of art, Van Gogh’s *Wheat field*, is purchased for the astonishing sum of $57 million as an investment. The problem of the determination of prices and their relations to *value* lay at the heart of nineteenth-century classical *political economy*, but it is an enormously complex problem that really has not gone away or in any sense been solved. The ‘metaphysical subtleties’ that Karl Marx refers to are very much about the misunderstandings that arise from the way we think about prices, and what we might call the sociology or social life of commodities. But if there is more to commodities than their physical properties and their prices, which are derived from costs of production or supply and demand curves, then there is a suggestion
that commodities are not what they seem. Commodities have strange, perhaps ‘metaphysical’, effects. For example, the fact that a beautiful Caravaggio painting is a commodity – and correlative, that it is private property and only within the means of the extravagantly rich – fundamentally shapes my experience of the work, and of my ability to enjoy its magnificent beauty in some unalloyed way. Its commodity status has tainted and coloured my appreciation of it.

A commodity, then, appears to be a trivial thing but it is in fact bewildering, even theological. The commodity, said Walter Benjamin, has a phantom-like objectivity, and it leads its own life after it leaves the hands of its maker. What on earth might this mean?

One way to think about the commodity is derived from Karl Marx, who begins his massive treatise on capitalism (Volume 1 of Capital) with a seemingly bizarre and arcane examination of the commodity, with what he calls the ‘minutiae’ of bourgeois society. The commodity, he says, is the ‘economic cell form’ of capitalism. It is as if he is saying that in the same way that the DNA sequence holds the secret to life, so the commodity is the economic DNA, and hence the secret of modern capitalism. For Marx, the commodity is the general form of the product – what he calls the generally necessary form of the product and the general elementary form of wealth – only in capitalism. A society in which the commodity is the general form of wealth – the cell form – is characterized by what Postone (1993, p. 148) calls ‘a unique form of social interdependence’: people do not consume what they produce and produce and exchange commodities to acquire other commodities.

But the commodity itself is a queer thing. Because while it has physical qualities and uses, and is the product of physical processes that are perceptible to the senses, its social qualities – what Marx calls the social or value form – are obscured and hidden. ‘Use value’ is self-evident (this is a chair that I can use as a seat and that has many fine attributes for the comfort of my ageing body) but value form – the social construction of the commodity – is not. Indeed, this value relation – the ways in which commodities are constituted, now and in the past, by social relations between people – is not perceptible to the senses. Sometimes, says Marx, the social properties that things acquire under particular circumstances are seen as inherent in their natural forms (i.e. in the obvious physical properties of the commodity). The commodity is not what it appears. There is, then, a hidden life to commodities and understanding something of this secret life might reveal profound insights into the entire edifice – the society, the culture, the political economy – of commodity-producing systems. It is possible to construct a diagrammatic ‘biography’ of the broiler from production to consumption, which depicts many of the actors involved in the commodity’s complex movements and valuations. This is a commodity circuit or a commodity chain (in French, it is referred to as a filière). Commodity circuits can depict different types of commodity chains and contrasting commodity dynamics.

Marx invoked commodity fetishism to describe the ways in which commodities have a phantom objectivity. The social character of their making is presented in a ‘perverted’ form. By this, he meant a number of complex things: first, that the social character of a commodity is somehow seen as a natural attribute intrinsic to the thing itself; second, that the commodities appear as an independent and uncontrolled reality, apart from the producers who fashioned them; and, third, in confusing relations between people and between things, events and processes are represented as timeless or without history, they are naturalized. Another way to think about this is that commodity production – the unfathomable swirl of commodity life – produces particular forms of alienation and reification. In his book Society of the spectacle (1977), Guy Debord argues that in a world of total commodification, life presents itself an as immense accumulation of spectacles. The spectacle, says Debord, is when the commodity has reached the total occupation of social life and appears as a set of relations mediated by images. The great world exhibitions and arcades of the nineteenth century were forerunners of the spectacle, celebrating the world as a commodity. But in the contemporary epoch, in which the representation of the commodity is so inextricably wrapped up with the thing itself, the commodity form appears as spectacle, or as a spectacular event, whether four men trying to play chicken or a chef playing football with a frozen broiler. Whatever else it may be, the terrifying events of 11 September 2001 and the collapse of the twin towers of the World Trade Center represented an enormous spectacle in the Debordian sense; and a spectacle for which there could be no spectacular response of equal measure. Necessarily, this spectacle of spectacles was a product of commodification and necessarily it has become a commodity itself. Within weeks of the attacks,
Ground Zero in New York City had become a small marketplace for 9/11 T-shirts and other mementos, just as shirts bearing the image of Osama Bin Laden and the falling towers were selling like hot cakes in Bangkok, Jakarta and the West Bank as icons of anti-imperialism.

We began with the commodity as a trivial thing and have ended with a world of commodities that ‘actually conceals, instead of disclosing, the social character of private labour, and the social relations between the individual producers’ (Marx, 1976 [1867], pp. 75–6). But this hidden history of the commodity allows us to expose something unimaginably vast; namely, the dynamics and history of capitalism itself. The commodity as its ‘cellular form’ is surely one of the keys to unlocking the secrets of what Max Weber (2001 [1904–5]) called the ‘capitalist cosmos’.

**commodity chain/filière** A collection of interrelated economic activities and industries that produce a particular kind of product or service. While commodity chains connote ‘vertical’ coordination among firms, from design to assembly to final distribution, the term seems to have first been used by Hopkins and Wallerstein in 1977 in a programmatic call to de-centre the NATION-STATE in international political economy. Coming from the perspective of world systems theory (see CORE-PERIPHERY MODEL), they argued for attention to be paid to ‘the widespread commodification of processes’ by ‘tak[ing] an ultimate consumable item and trac[ing] it back to the set of inputs that culminated in this item – the prior transformations, the raw materials, the transportation mechanisms, the labor input into each of the material processes, the food inputs into the labor’ (p. 128). The alternative – and more common – usage of this concept seems to have independent origins in agro-food studies (see AGRO-FOOD SYSTEM), representing a rare case in which AGRICULTURAL GEOGRAPHY led the way in economic geography. Friedland, Barton and Thomas (1981) first use of the term ‘commodity systems analysis’ to focus on the mutual interaction of agricultural production practices, grower organization, labour, science and extension, and marketing and distribution systems, which was quickly followed by the actor-oriented variant associated with Wageningen University to emphasize how the specificity of farm labour processes can give rise to different styles of FARMING (van der Ploeg, 1985).

For some scholars, the utility of commodity chains is largely descriptive, a lens through which to examine industrial organization and/or economic geography. For instance, the global commodity chain approach, most associated with Gary Gereffi and his colleagues, focuses on the transnational reach of inter-firm networks of manufacturers, suppliers and subcontractors to each other, and to markets. In respect to the strong coordination role that apparel design firms started to play in the 1980s, they also suggested an epochal shift from producer-driven to buyer-driven chains. Recently, they have posited the existence of regulation- or consumer-driven commodity chains, in light of the increased salience of ethical products and the increasing power of private systems of regulation to construct and ensure quality in certain spheres of commodity production (see Gereffi, Humphrey and Sturgeon, 2005).

One variation on this approach is value chain analysis, which draws attention to how surplus distribution along a given chain is a function of rent-generating barriers to entry, which are in turn a function of chain governance (Kaplinsky, 2004). Kaplinsky and others have argued that that national DEVELOPMENT prospects can be improved by industrial ‘upgrading’ to higher value-added processes.

For another set of scholars, the commodity chain approach is a tool of radical scholarship, in that it has the potential to make the workings of CAPITALISM more transparent, particularly because GLOBALIZATION seems to make most commodities inscrutable as to how they are made and distributed (Hartwick, 1998). Other geographers, notably Leslie and Reimer (1999), are critical of the notion that commodities can be ‘unveiled’. Leslie and Reimer have also remarked that commodity chains privilege FLOWS relative to SCALE. JGU

**common pool resources** Resources, usually natural, from which it is difficult to exclude users, and whose use reduces resource availability for others (Ostrom, Dietz, Dolsak, Stern, Stonich and Weber, 1999). Contra the tragedy of the commons thesis and its calls for privatization or centralized state control, common pool resources have often been governed sustainably by common property regimes, whose rules are structured around the resource’s size, mobility, renewability and other characteristics. Common pool resources thus differ from true open access resources. It is unclear, though, whether and how these lessons can be ‘scaled up’ to address contemporary problems at larger scales, with more users and greater rates of change.

**common property regimes** Forms of ownership and access whereby all or parts of a local environment are owned and managed by a community. This differs from private ownership, state ownership and open access regimes, where nobody owns the environment.

Common property regimes have existed for thousands of years. They have become more popular as indigenous practices are recognized and validated, and the limitations of state ownership, top-down management and private property become increasingly apparent. Common property regimes may be particularly suited to ‘resources’ where it is possible to restrict access, but private ownership, while possible, is a very costly way to manage the resource.

**communication(s)** The geography of communication treats the sending, receiving and exchange of information and messages face-to-face or via other means (letters, media, telephone, Internet). Because communication is essential to social relations, it is central to many of the processes of interest to human geographers, such as the construction of difference, the definition of community, the causes and consequences of segregation and the conduct of social movements. At issue is who has access to what information, and how space, place and networks shape this access.

Despite the power of information technology to enable communication at a distance (see time–space compression; time–space convergence; time–space distanciation), face-to-face communication is still prized in many theories in human geography. In economic geography, for instance, the spatial agglomeration of certain types of industry (such as software development, the film industry or watchmaking) in industrial districts is seen as a prime facilitator of innovation: the key motivation for such agglomerations is believed to be the ease of face-to-face communication, which many see as necessary to the development of trust in social interactions (Murphy, 2006). In urban geography, the desire for relatively easy face-to-face communication is seen as the main rationale for the clustering (see clusters) of producer services in dense urban areas. Information exchanged face-to-face in social networks is also important to the functioning of labour and housing markets, because large numbers of people learn about and evaluate employment and housing options via such channels. Because the nature of the information exchanged, including its locational dimensions, depends in part on the characteristics of the people in a social network, the social identity of network constituents is important. In sum, the process of face-to-face communication plays an important role in concentrating certain types of human activity in certain places and in certain groups of people.

Because telecommunications permit communicating over great distances, questions arise as to the power of such technologies to support the dispersal of human activity. Will information technologies such as the Internet and video conferencing undermine the raison d’être for urban agglomerations and industrial districts (i.e. the need for face-to-face contact)? In addressing this question, geographers have examined the extent to which communication via technology is a substitute for face-to-face interaction (in which case one might expect greater dispersal of human activity), a stimulus to face-to-face interaction (in which case one would expect information technologies to lead to a greater demand for face-to-face contact and therefore increased agglomeration effects) or a complement to personal contact (in which case one might expect information technologies to have little impact on the concentration or dispersal of human activity) (Janelle, 2004).

**communism** A tradition of thought based on the principle of the communal ownership of property (primitive communism) and common ownership of the means of production (full communism). Although traceable back to ancient Greece, in its modern form it is most widely associated with the writings of Karl Marx, especially *The communist manifesto* (Marx and Engels, 2002 [1848]). Writing at the height of the industrial revolution, Marx observed the increasing exploitation of newly urbanized wage labourers (the proletariat), and the widening gulf between the rich and the poor. He argued that the socio-economic system known as capitalism was responsible for the exploitation and alienation of these labourers, and that only by transcending it through revolutionary struggle could society advance to a better system, that of communism. In communism, all private property is abolished, there are no discernible classes and the people are self-governing. In pure communism the state is unnecessary, but according to Marx and most of his followers, communism will be preceded by a transitional stage called socialism, in which the state plays a major role.

Although pure communism has never been implemented, Marxist theories were central in galvanizing workers' movements in Europe in the late nineteenth century, and socialist governments became important players on the world stage following the Russian Revolution of 1917. After the Second World War, many more communist parties came to power and established regimes in Eastern Europe under the aegis of the Communist Party of the Soviet Union. The victory of Mao Zedong and the establishment of the People's Republic of China in 1949 was another major turning point in the growth and spread of communist ideology. Other countries in Asia and Africa, including Vietnam, North Korea, Laos, Mozambique and Angola, adopted some form of communist principles of government over the following years.

With the expansion of new forms of neo-liberal governance and the introduction of glasnost (openness) by the Soviet leader Mikhail Gorbachev in the 1980s, communist ideology began to wane. Over the past decade numerous geographers have explored the social and spatial repercussions of the transition to a post-communist world, especially in the former satellite countries of the USSR (see especially Pickles and Smith, 1998; Rainnie, Smith and Swain, 2002: see post-socialism). Others have interrogated the implications of communism's disintegration for theory and intellectual movements (see Burawoy, 2000). In both cases, the break-up of state planned and regulated societies has had enormous ripple effects, with ongoing ramifications in the context of increasing American dominance on the global stage. Marx and Engels (1972 [1845]).

**communitarianism** Both a political and an intellectual programme, communitarianism affirms the values and procedures of community, and rejects the political and analytical premises of individualism, while worrying at the effects of industrialization and urbanization on community life (Smith, D.M.J 1999a). Under the direction of writers such as Amitai Etzioni (1994), as well as critics of liberalism, such as Michael Sandel, communitarianism has enjoyed a resurgence in the past decade. However, one can find precedent in the work of those such as Emile Durkheim, who also traced the disorganizing effects of modernity. Contemporary communitarians argue for a new moral and social order based on shared values that bridge tradition, such as moral ties of family, with modern norms of tolerance and inclusion. NKB

**community** A group of people who share common culture, values and/or interests, based on social identity and/or territory, and who have some means of recognizing, and (inter)acting upon, these commonalities. The definition is contentious, however, and Joseph (2002) has suggested that community is less about social identity and more related to practices of production and consumption under capitalism. Community is frequently used to connote a scale at which people can easily interact and recognize one another, although as Anderson (1991a [1983]) argued in relation to nations, community can be 'imagined' and actualized through media and culture rather than interpersonal interaction.

The Chicago School of sociologists saw community as the basis for social organization, and their usage fostered a connotation with neighbourhoood. The use and propagation of community as related to urbanism by the Chicago School drew upon, but also reinterpreted, notions of community from German sociologists such as Ferdinand Tönnies (1855–1936). Tönnies envisioned community (Gemeinschaft) as one’s family and intimate life, while society (Gesellschaft) was an ‘imaginary
and mechanical structure’ (Tönnies, 1955 [1887], p. 37). For Tönnies and the Chicago School, urban neighbourhoods could provide the kind of mutual support required for a community such as that found in a ‘rural village’ (Tönnies, 1955 [1887], p. 49; Park, 1967 [1925]). Nonetheless, in Tönnies’ formulation, community was being replaced by society through URBANIZATION and INDUSTRIALIZATION. Although Tönnies acknowledged a possibility of community in urban neighbourhoods, his formulation situated community primarily in pre-industrial rural settings. Equating community with the intimacies of village life, however, fails to acknowledge the political and economic inequalities inherent to such a setting – Joseph (2002, pp. 4–5) cites Williams (1973) on this point.

Tönnies’ (2001 [1887]) conceptualization of community as a traditional ‘rural’ phenomenon sets it in opposition to or pre-dating industrial capitalism (Bender, 1978; Joseph, 2002). This conceptualization fosters and supports claims such as that of communitarians – exemplified by Etzioni (1993) and Bellah, Madsen, Sullivan, Swidler and Tipton (1985). These scholars see community as missing from, or left behind by, recent development. They seek a return to mutual support and responsibility, which, they argue, form the basis of community and social values (Bellah, Madsen, Sullivan, Swidler and Tipton, 1985). Such notions of community have been important to the GOVERNANCE strategies of the neoliberal STATE (Herbert, 2005: see also NEO-LIBERALISM). These strategies – such as welfare reform and community POLICING – transfer to individuals or groups of citizens’ activities and roles that were formerly assumed by the state. But Herbert (2005) argued that many communities – often conflated with neighbourhood from Chicago School formulations in these state devolutions – are unable and unwilling to assume these tasks, thus fostering a disconnect between ideals of community and actual experiences of them in neoliberalism.

The failure of community to act in lieu of the state highlights its status under capitalism. Seeking to challenge the notion of community as antecedent of and potentially in opposition to the individualization of capitalism, Joseph (2002) argued that capitalism actually produces community. In her view, community is not merely or primarily a set of shared social identities, although it is often depicted as such in identity politics (for an example, see Young, 1990a). Instead, community is performed (see PERFORMATIVITY) and practiced through relations and practices of production and CONSUMPTION: ‘Marx articulates the necessary role that historically particular and differentiated social formations play as the bearers of capital, as the medium within which capital circulates . . . ’ (Joseph, 2002, p. 13). Community is a way that people articulate use values within the circulation of production and consumption, thereby supplementing and particularizing the abstractness of CAPITAL. Joseph’s (2002) formulation of community as operating in and through capitalism forces reconceptualization of it as a positive reaction or antidote to capitalism. It may support or disrupt capital, but neither outcome is evident a priori (Joseph, 2002). Instead, scholars need to attend to the particularities of community; how it is produced and performed discursively and in practices, and to what end. DGM

**commuting** The daily journey to work, implying a repetitive daily trip from a fixed home location to a fixed work location. The term dates to the mid-nineteenth century, when wealthy businessmen began travelling from their suburban dwellings to their urban worksites via railroad: the ‘commutation’ of their daily tickets to lower-priced monthly fares led to the term ‘commuter’ (Muller, 2004). The peaking of journeys to and from work during the morning and evening rush hours and associated road congestion have been a prime focus of transportation planning since the 1950s. **Telecommuting** involves using information technology to work while the worker is not physically in the workplace.

**compact city** A policy goal associated with advocates of SUSTAINABILITY in Western-world URBAN PLANNING. Proponents seek to mitigate automobile-related energy use, urban air pollution, and SPRAWL-related farmland and habitat loss by promoting the re-use of urban brownfield sites, high-density and mixed-use development, and public transit. The compact city ideal permeates discussions of urban SPRAWL, smart growth, QUALITY OF LIFE and questions of urban housing availability and affordability. A range of opinions exist on the veracity, feasibility and acceptability of the compact city as a model for achieving urban sustainability, from outright advocacy, to
considered evaluation (Breheny, 1995), to strong scepticism (Neuman, 2005).

**comparative advantage** The principle whereby individuals (or territories) produce those goods or services for which they have the greatest cost or efficiency advantage over others, or for which they have the least disadvantage. The outcome tends to be specialization across places. A gifted individual or resource-rich region may be able to produce everything more efficiently than others that are less well endowed, but as long as some comparative advantage exists, specialization may benefit all. An example is that of the best lawyer in town who is also the best typist: it pays the lawyer to concentrate on the lucrative practice of the law and hire a typist (who has a comparative advantage in typing relative to knowledge of the law). One region may be able to produce two goods more efficiently than another region, but it pays to concentrate on the good for which there is greatest comparative advantage and buy the other from the second region.

The notion of comparative advantage is important in understanding regional specialization, whereby all regions gain from the interchange of products even if they could satisfy their own needs (cf. complementarity). A condition for realizing the benefits of comparative advantage is free trade. At the international scale, market imperfections such as tariff barriers can impede specialization based on comparative advantage, protecting domestic production of goods that could not withstand open competition. The objective may be to ensure more ‘balanced’ economic development and to avoid problems associated with narrow product specialization.

**competitive advantage** The relative ability of firms in the same market to win above-average profit levels, through either cost or product differentiation advantages. These may result from either a superior resource base (e.g. better facilities, superior quality of workforce), greater capability to utilize its available resources (capability advantages) and/or a better-quality product. That competitive advantage may be only transient; it is sustainable if it cannot be challenged by other firms.

Competitive advantage is also used to account for the emerging division of labour, rather than the theory of comparative advantage. Places may compete for employment – as, for example, in many service industries, including leisure and tourism – on the basis that what they have to offer is superior to that available in other places, so that spatial differentiation results from competitive success rather than differential resource availability or efficiency.

**complementarity** The existence of complementarity between two regions implies that one produces (or has the potential to produce) goods or services for which the other suffers from a deficit (or potential deficit). Ullman (1956) used the term to describe one of the bases of spatial interaction, arguing that complementarity may arise either from areal differentiation (in resource endowment, or in social, economic and cultural conditions) or as a result of economies of scale (cf. comparative advantage).

**complexity theory** A term for the study of ‘complex systems’ that is used in both mathematical systems modelling and in qualitative and discursive work. Complex systems are non-linear, interdependent and strongly coupled systems with feedback loops, and may exhibit scale-effects, together with sensitivity to initial conditions and path-dependence. The original use of the term is for the mathematical properties and analysis of such non-linear interdependent systems, and embraces both chaos theory and catastrophe theory as sub-branches. Many studies identify three divisions of mathematical complexity theory: algorithmic or computational complexity; deterministic complexity; and ‘aggregate complexity’.

*Algorithmic complexity* deals with the relative computational difficulty of computable functions. This may appear the least relevant division for human geography, but is important in understanding the difficulties of solving large-scale spatial optimization problems and other aspects of geographic information systems and spatial analysis. *Deterministic complexity* examines the properties of non-linear systems and subsumes both chaos theory and catastrophe theory as particular subsets. The third division of aggregate complexity considers systems of linked components or subsystems and examines the ways in which order and structure may emerge at higher levels.
from the interactions. A classic example is the highly organized termite hill that emerges out of the interaction of countless highly specialized individual termite activities. Such properties of ‘self-organization’ and ‘emergence’ are central to aggregate complexity.

Several different attempts have been made to develop and apply the mathematical theory to urban and regional systems, such as Allen (1997) and Portugali (2000). One difficulty is defining the objects within the system and its boundaries. Reviews of these issues and their relevance for human geography may be found in Manson (2001) and O’Sullivan (2004). Wilson (2000) takes a pragmatic approach, using complexity theory as a framework within which to link various urban sub-models, arguing that such linkage is vital to understand urban structure; however, this cannot be done in analytical terms, but only through computer simulation and sensitivity analysis.

Complexity theory has also been adopted by cultural geographers (see CULTURAL GEOGRAPHY) as an analogical and metaphorical tool: as the ‘CULTURAL TURN’ emphasized the importance of DIFFERENCE, contingency and context, so the various concepts, MODELS and terms within mathematical complexity theory provided useful language and METAPHORS with which to examine space and society. Within human geography, this use of complexity theory outnumbers the mathematical applications. A well-developed example is provided by Urry’s study of ‘global complexity’ (Urry, 2003), in which complexity is used to link together local and global, the emergence of global ‘order’ from regional ‘disorder’, the role of feedbacks and path dependence in how regions engage with global society, and the challenge for how social theory is constructed. Thrift (1999b) gives a wide-ranging survey of the take-up of the complexity metaphor in both business and the social sciences.

confirmatory data analysis Quantitative statistical procedures used to evaluate HYPOTHESES, usually involving the use of SIGNIFICANCE TESTS (cf. EXPLORATORY DATA ANALYSIS).

conflict At its most general, ‘conflict’ can mean anything from a personal disagreement between two people to a world war. It is now widely understood that conflict is part of the human condition, although only some of it results in overt VIOLENCE or combat. Conflict theory in sociology emphasizes struggles over RESOURCES and the formation of groups and social cleavages that may lead to organized conflict. Coercion, resistance, revolt and political violence within states, and warfare between states, are dynamic processes in which escalation, violence, conflict resolution and peace-making are all vitally important. In political science and economics, conflict is sometimes discussed in terms of GAME THEORY and strategic calculation, an approach that has not been frequently invoked by geographers.

Themes of conflict run through numerous facets of contemporary enquiry in HUMAN GEOGRAPHY, even though they are often not theorized as such. Marxist approaches emphasize the importance of structural conflict between classes and especially in cities under CAPITALISM, where the geography of CLASS struggle is literally built into the urban structure (see MARXISM). More recently, feminist analyses have investigated numerous conflicts generated by patriarchal structures and the strategies of resistance used by women (Staeheli, Kofman and Peake, 2004: see also FEMINISM; PATRIARCHY). MIGRATION brings peoples and cultures into conflict as newcomers and established populations negotiate coexistence, frequently in situations of considerable economic change and against a backdrop of class and gender struggles. Identity conflicts are part of the urban mosaic in most metropolitan centres, where diasporic populations (see DIASPORA) are now the subject of numerous geographical analyses inspired by POST-COLONIALISM (Jacobs, 1996).

Classic GEOPOLITICS focused on the geography of war and international rivalry, a topic that has undergone a revival of interest since the 1980s. Most recently, conflict is at the heart of a series of geographical analyses of matters of WAR and peace, where TERRITORY, IDENTITY, national independence, EMPIRE and violence have all come under scrutiny in the aftermath of the events of 11 September 2001 and the launch of the ‘global war on terror’ by the Bush administration in the USA (see TERRORISM). Here, conflict is discussed at the largest scales as matters of clashes between CIVILIZATIONS and cultures, but CRITICAL GEOPOLITICS also reveals the multiple ways in which these struggles are socially constructed and reach into the lives of ordinary people (Gregory, 2004b). These terms are heavily laden with both implicit and explicit geographical thinking, a matter that has gained

Conflict Commodities Across the global South, the dependence upon a strategic natural resource (oil, diamonds, copper) has been associated with a cluster of poor human, economic and political development indices, an association that has been called the 'resource curse'. These pathologies appear especially robust in extractive economies; for example, the petro-states of the Gulf of Guinea, which are classic rentier economies marked by deplorable corruption, poor economic performance, authoritarian politics, miserable social achievement and civil conflict (including civil war), against a backdrop of enormous oil wealth. Paul Collier and his colleagues at the World Bank (2003) developed a model of what they called the 'economics of civil war' in which resource-dependent economies (especially minerals) could be sought out and looted by rebel groups. The ease with which resources such as diamonds and oil could be extorted, stolen or tracked down by groups were driven, in their view, by greed and criminality rather than grievance. Civil conflict always surrounded resource-dependent economies in which the character of the resource – point or diffuse, proximate or remote (see Le Billon, 2005) – determined the particular forms of violent politics (coup d'état versus secessionist movements). Conflict commodities refer to the association between state dependence upon particular commodities and the ease with which rebels could plunder the resource in order to fund their war (organized crime in the World Bank's account) against the state. The case of 'blood diamonds' gained international attention because of the ways in which alluvial diamonds and their trade could be easily controlled by rebel groups in the extraordinarily violent civil conflict in Sierra Leone. As a result of the pressure by activist groups such as Global Witness, the Kimberly Process Certification Scheme was set up in January 2003 as an international governmental certification system to prevent the trade in diamonds that funded or sustained civil conflict (see Global Witness, n.d.).

Conservation A term that implies the keeping or preservation of something for future use and human benefit. The word can be applied to buildings or to food, but it is mostly used to refer to the natural environment, natural resources, and particularly species and habitats. Concern for non-human nature has a long history; for example, in classical Mediterranean societies, and in the early European tropical colonial empire (Grove, 1995). In its modern form, conservation became established as a body of thought and social action towards the end of the nineteenth century.

Two aspects of the conservation of the environment have been important since the late nineteenth century. The first concerns the rate at which resources, particularly renewable resources (such as living species), are consumed. The second concerns the desire to ensure the survival of species and habitats. The distinction between these two is commonly exemplified by the sharp debate in the USA in the early years of the twentieth century between the utilitarian view of conservation of Theodore Roosevelt's adviser, the forester Gifford Pinchot, and the more romantic preservationist arguments of the Sierra Club and John Muir (Hays, 1959). However, these two aspects of conservation are still in tension today; for example, between those who argue that safari hunting and a legal trade in ivory are an appropriate and effective way of conserving species such as elephants in Africa, and those who feel that such hunting and trade can never be controlled in a way that guarantees sustainable harvests and that does not promote illegal killing.

The technical basis of ideas about conservation of renewable resources draws on a number of areas of natural science, particularly the science of fisheries management. In the late nineteenth century, fish catches began to decline systematically in Europe and the USA as fishing became industrialized with the advent of steam-driven boats and other innovations. The International Conference for the Exploration of the Sea in 1899 proposed scientific enquiries to promote rational exploitation. By the 1930s the idea of a maximum sustainable yield was established, and through the first half of the twentieth century a series of international institutions were established to try to regulate fishing, including
the Overfishing Convention agreed in London in 1946, and the International Whaling Commission established in Washington in 1946. Neither these, nor their successors, achieved the sustained exploitation of any significant open-water stock of fish or marine mammals. The boom–crash cycle of sealing in the nineteenth century, and of the herring fishery in the North Sea, ocean whaling and Atlantic cod fishing in the twentieth century, provide ample evidence of both the desirability of conservation and the political and economic difficulty of making conservation strategies work (Cushing, 1988).

The language of fisheries science suggests the considerable influence of economics: stocks were renewed or depleted, and calculations included estimates of catch per unit effort. In turn, economics reflected evolving understanding of the dynamics of resources, particularly in the distinction between renewable (flow) and non-renewable (stock) resources (Ciriacy-Wantrup, 1952). Such ideas have been widely applied; for example, in soil erosion and forestry. The US Dust Bowl stimulated concern about the management of soil resources in a way that could sustain production around the world; for example, in tropical Africa, where it provided the legitimization for widespread and unpopular compulsory terracing (Beinart and Coates, 1995). The concept of sustained yield forestry is long established, although its application to old-growth temperate forests (where ‘tree farming’ is regarded as environmentally highly destructive), and the failure to apply its principles to tropical regions forests remain highly controversial.

At the end of the nineteenth century, the extinction of species such as the quagga (a barely striped plains zebra from the African Cape) and the North American passenger pigeon, and the near-extinction of others such as the American bison, became the rallying points for a species conservation movement in the USA, Europe and the colonial world (Sheail, 1976; Adams, 2004). This movement drew in particular on zoos (Sheail, 1976; Adams, 2004). This movement in the USA, Europe and the colonial world points for a species conservation movement as the American bison, became the rallying pigeon, and the near-extinction of others such Cape) and the North American passenger barely striped plains zebra from the African

consumption  Conventionally, the act of purchasing and using Commodities, although some commentators insist that the term should also refer to their transformation, resale and exchange (Gregson and Crewe, 2003). Although Economic geography has traditionally focused on spaces of Production, there has been a significant rise of interest in consumption since the 1980s, accompanied by increased dialogue between economic and Social geography. One reason for this is the putative shift to a Post-industrial society, where Retailing, Leisure and Tourism are widely identified as major engines of growth (in the west, at least). Another is the theorized importance of consumerism as a locus for identity: in the consumer society, what we buy has seemingly become more important in defining our sense of self than what we produce. Finally, the rise of interest in consumption appears to be related to important trends
in GLOBALIZATION, with place-related consumer cultures (such as national cuisines or musics) having been largely replaced by a landscape of hybrid commodity flows (see FOOD, HYBRIDITY, MUSIC, TRANSCULTURATION).

Some of the features taken to be characteristic of contemporary consumption are likely facets of MODERNITY (Glennie and Thrift, 1992). Indeed, some argue that the consumer revolution actually preceded the INDUSTRIAL REVOLUTION, with innovation in production being fuelled by changes in consumer tastes and mores. Historical geographies of retailing thus reveal a remarkable series of INNOVATIONS in the design, advertising and selling of goods through the eighteenth and nineteenth centuries, with a succession of carefully orchestrated spaces – including market halls, arcades and department stores – playing a major role in imbuing products with an aura of desirability (Wrigley and Lowe, 2002). In the era of high MODERNISM, cultures of consumption were also very much associated with the attainment of security and comfort, with the idealization of the SUBURBS reflected in a plethora of products that no HOME could possibly be without. The domestication and suburbanization of consumption was mirrored in the de-centring of consumption, with retailing and leisure following the middle classes into the SUBURBS; simultaneously, however, mass transportation allowed the city centre to enhance its role as a space of consumption, with CINEMA-going, nightclubbing and eating out becoming key urban rituals, maintaining the myth that city centres provided a vibrant PUBLIC SPHERE.

The mid-twentieth century has thus often been characterized as an era of ‘high mass consumption’. Nonetheless, Bauman (2001a) suggests that consumption remained subordinate to work throughout this period. As he describes, work served as the link holding together individual motivation, social integration and systemic reproduction, with consumer goods primarily regarded as rewards for work. Furthermore, in industrial producer societies, the STATE provided some of these rewards to workers through collective provision, so even the unemployed could participate in rituals of consumption. However, in POSTMODERN, deindustrialized societies, the state has little interest in tending this ‘reserve army of labour’. Hence, the WELFARE STATE ‘safety net’ has gradually eroded, with individuals forced to search for security in the marketplace. (see NEO-LIBERALISM. Luckily (at least for some), contemporary consumerism implies that for every human problem there is a solution that can be purchased: even problems of over-consumption (e.g. obesity) fuel the marketing of new commodities (e.g. diet products, health club subscriptions, plastic surgery).

The second consumer revolution has thus heralded an era in which consumption, not work, is the hub around which identity revolves. Yet, as Appadurai (1996, p. 38) insists, ‘consumption has now become serious work’, and it is wrong to imply that consumer-led societies are any less disciplined than industrial ones. Indeed, consumerism has arguably bequeathed a new mode of social control, where the fundamental social divide is not between bourgeois and proletariat, but between the creditworthy seduced – those whose appetite for consumption fuels a huge leisure, recreation and service sector – and the repressed – those ‘flawed consumers’ who are unable to enjoy a life of conspicuous consumption (Clarke, 2003). While the former are drawn into purchases through a panoply of subtle (and not so subtle) marketing, it also requires SURVEILLANCE to exclude the repressed from spaces of leisured consumption. CCTV, security guards, credit-rating mechanisms and consumer profiling are all significant in this process, maintaining the order of consumer spaces designed for the affluent.

The way in which shopping malls combine such mechanisms of social control with a carefully orchestrated ambience has led many geographers to proclaim them as paradigmatic consumer settings:

Developers have sought to dissociate malls from the act of shopping. That is, in recognition of the emptiness of the activity for which they provide the main social space, designers manufacture the illusion that something else other than mere shopping is going on. The product is effectively a pseudo-space that works through spatial strategies of dissemblance and duplicity. (Shields, 1989)

Given that the acquisition of COMMODITIES has become so central to developing a sense of self, exclusion from such spaces must be regarded as a significant dimension of SOCIAL EXCLUSION (Williams and Hubbard, 2001). However, accounts focusing on seductive spaces of consumption perhaps ignore the more routine spaces where the majority of consumption occurs (e.g. supermarkets, corner shops, takeaways). Likewise, the emergence of new spaces of ‘second-hand’ consumption (e.g. eBay) also
transnationalism

The impact of local environments on individuals’ attitudes and behaviour. Much social science is based on compositional effects, whereby attitudes and behaviour are influenced by individuals’ nongeographical position within society, such as their social class: within any society, people from similar backgrounds are assumed to behave in similar ways, wherever they live. According to arguments regarding contextual effects, however, because attitudes and behaviour patterns are to a considerable extent learned through social interaction in places (such as households and neighbourhoods), similar people living in different sorts of places may think and act differently as a result of interactions with their neighbours. Furthermore, many patterns associated with compositional effects may themselves be the results of aggregating contextual effects. If behavioural norms are learned from local models, national patterns are simply summations of those local practices over all places: the national is an aggregation of the local.

The terminology regarding contextual effects varies across disciplines. In economics, for example, Brock and Durlauf (2000) distinguished among: endogenous effects, whereby one individual’s behaviour is causally influenced by that of other group members (cf. endogeneity); exogenous effects, according to which individual behaviour varies with the observed attributes that define group membership; and correlated effects, on the argument that individuals in an area tend to behave in similar ways because they either have similar characteristics or face similar opportunities and constraints.

The contrast between compositional and contextual effects strongly influenced thinking within human geography in the 1980s, as characterized by Thrift’s (1983) seminal paper in which he deployed the structuration approach to appreciate various forms of behaviour (such as the ‘life path’) as compositional orderings within contextual fields. Citing Thrern, he argues that ‘being in the world’ involves both inclusive (being a member of a meaningful world) and positional (having a particular place in the world as defined by characteristics such as gender, ethnicity etc.) characteristics and that the processes of becoming – learning about one’s positional situations – are structured contextually in locales.

Contextual effects underpinned much of the early work on diffusion, notably through Torsten Hägerstrand’s operationalization of social contact and influence through the concept of the mean information field, and their production was central to his conception of time-geography. More recently they have been widely explored within electoral geography, with studies showing that people are very likely to share political attitudes with and to vote in the same way as (the majority of) their neighbours, irrespective of their social positions (cf. neighbourhood effect). They have also been identified in other fields, as in studies of morbidity and mortality in medical geography and of school effects

raises important questions about the relationship between repressed and seduced.

Alongside the attention devoted to the socialities of consumption, there is significant work by geographers on the subjectivities created through acts of consumption. For instance, the centrality of consumption in constructions of the body is of growing interest (Valentine, 1999), as is the emotional connection forged between people and the things that they consume. Some are even beginning to explore the emotional labour required to dispose of old goods, noting they may be incorporated into our personal biographies in profound ways (Gregson and Crewe, 2003). The fact that consumer goods may have long and complex lives is also something that geographers have explored through attempts to chart global commodity chains and the ‘traffic in things’ (Jackson, 1999). Transcending simple distinctions between production and consumption, tracing webs or networks of commodity circulation not only offers an important perspective on transnationalism; it also draws attention to the range of technologies, spaces and bodies involved in practices of consumption.

Although consumption was once regarded as marginal to geographical enquiry, the sheer variety of recent studies suggests that it is now impossible to ignore the spatiality of consumption. Indeed, perhaps the main impediment to the development of geographical theories of consumption is the current ubiquity of consumer studies. Having quickly reached a point at which a bewildering range of activities are understood to involve consumption, a key challenge facing human geographers is to decide whether consumption remains a useful concept around which to orient a vast and complex literature. contextual effect
The impact of local environments on individuals’ attitudes and behaviour. Much social science is based on compositional effects, whereby attitudes and behaviour are influenced by individuals’ nongeographical position within society, such as their social class: within any society, people from similar backgrounds are assumed to behave in similar ways, wherever they live. According to arguments regarding contextual effects, however, because attitudes and behaviour patterns are to a considerable extent learned through social interaction in places (such as households and neighbourhoods), similar people living in different sorts of places may think and act differently as a result of interactions with their neighbours. Furthermore, many patterns associated with compositional effects may themselves be the results of aggregating contextual effects. If behavioural norms are learned from local models, national patterns are simply summations of those local practices over all places: the national is an aggregation of the local.

The terminology regarding contextual effects varies across disciplines. In economics, for example, Brock and Durlauf (2000) distinguished among: endogenous effects, whereby one individual’s behaviour is causally influenced by that of other group members (cf. endogeneity); exogenous effects, according to which individual behaviour varies with the observed attributes that define group membership; and correlated effects, on the argument that individuals in an area tend to behave in similar ways because they either have similar characteristics or face similar opportunities and constraints.

The contrast between compositional and contextual effects strongly influenced thinking within human geography in the 1980s, as characterized by Thrift’s (1983) seminal paper in which he deployed the structuration approach to appreciate various forms of behaviour (such as the ‘life path’) as compositional orderings within contextual fields. Citing Therborn, he argues that ‘being in the world’ involves both inclusive (being a member of a meaningful world) and positional (having a particular place in the world as defined by characteristics such as gender, ethnicity etc.) characteristics and that the processes of becoming – learning about one’s positional situations – are structured contextually in locales.

Contextual effects underpinned much of the early work on diffusion, notably through Torsten Hägerstrand’s operationalization of social contact and influence through the concept of the mean information field, and their production was central to his conception of time-geography. More recently they have been widely explored within electoral geography, with studies showing that people are very likely to share political attitudes with and to vote in the same way as (the majority of) their neighbours, irrespective of their social positions (cf. neighbourhood effect). They have also been identified in other fields, as in studies of morbidity and mortality in medical geography and of school effects.
on student development (cf. EDUCATION). Although empirical studies have identified behaviours consistent with contextual effects, however, the processes assumed to produce them – for example, the role of social interaction in the spread of attitudes and behavioural norms – is less well understood. Indeed, in some situations it may be impossible to identify the causal impact of a local context because of an endogeneity effect whereby (some at least) individuals select their interaction contexts (as with working-class people who aspire to middle-class status and so choose to live in middle-class areas and send their children to local schools).

Jencks and Mayer (1990) suggested five mechanisms which can generate outcomes consistent with contextual effects:

1. **Epidemic effects**, whereby peer influences within an area spread to neighbours;
2. **Collective socialization**, whereby local role models are important ingredients in attitude development;
3. **Institutional models**, in which local institutions rather than people provide the influences;
4. **Competition models**, whereby neighbours compete for scarce resources; and
5. **Relative deprivation models**, which involve individuals comparing their situations relative to their neighbours' and act accordingly.

Two or more of these may be relevant in any particular situation.

**Contextuality** The situated character of social life, involving coexistence, connections and ‘togetherness’ as a series of associations and entanglements in time–space. The concept of context has deep historical roots. It is initiated in relations of language, and it has always contained some double sense of ‘circumstances’ and ‘connections’. Like text, context is a metaphor derived from the Latin *texere*, ‘to weave’, and in traditions of interpretation, context came to refer to the coherence of the text, the connections between the parts and the whole.

The term was translated into geography by the Swedish geographer Torsten Hägerstrand as part of the ontological and epistemological basis of time–geography. Hägerstrand (1974) distinguished between compositional approaches, which proceed by splitting up their objects into structural categories derived via formal–logical method, and contextual ones, in which objects and events are treated in their immediate spatial and temporal setting and attributed a property of ‘togetherness’ that must not be split asunder. In time–geography, trajectories of individual entities are represented in time–space, not as movements in an empty Cartesian time–space, but as bundles of activities together constituting a web of trajectories. Hägerstrand saw the idea of such a web as a basic postulate of the contextual approach. It should ensure an understanding of time and space as resources ‘drawn upon’ in the conduct of life. It does, however, remain debateable whether his reduction of human action to moving entities and his graphical illustrations still retained a sense of time and space as external frameworks.

Stripped of their connotations of ‘physicalism’, Hägerstrand’s ideas eventually intersected with threads in modern social theory and social philosophy pursuing ontologies of practice and understandings of the ‘situation’ for social action. In structuration theory, introduced by the British sociologist Anthony Giddens (1984), for example, contextuality does not denote boundaries of social life but, rather, features that are inherently involved in its construction. ‘All social activity’, it says, ‘is formed in three conjoined moments of difference: temporally, structurally and spatially; the conjunction of these express the situated character of social practices’ (Giddens, 1981, p. 30). Giddens provides a set of concepts that describe contextuality as inherently involved in the connection of social integration and system integration; of face-to-face interaction and more extensive relations of mediated interactions. One of them is the concept of locale, describing ‘settings’ of interaction connected to different social activities. Many geographers have worked in critical dialogue with these formulations. Pred (1984), for instance, pursues a ‘theory of place as historically contingent process that emphasizes institutional and individual practices as well as the structural features with which those practices are interwoven’. Simonsen (1991) adds a more phenomenological aspect by emphasizing the ‘situated life story’ in an approach to the constitution of social life involving the interaction between different modes of temporality and spatiality. In these, and other, contributions, a central point is that contexts are not passive backdrops. They are ‘performative social situations, plural events which are more or less spatially extensive and
more or less temporally specific’, and they are ‘productive time–spaces which have to be produced’ (Thrift, 1996).

Another thematic corresponds to epistemology. Several philosophical sources inform these discussions. Central are Martin Heidegger’s phenomenology and Ludwig Wittgenstein’s ideas of language games, somehow intertwining with Michel Foucault’s ideas of historically constituted and spatially formed ‘power–knowledge’. But also important is Karl Mannheim, a pioneer of the sociology of knowledge, who was one of the first to treat ideas as socially situated (Situationsgebunden). Part of these ideas, often mediated through Donna Haraway’s notion of situated knowledge, has induced a new understanding of the production of geographical knowledge. Knowledge production is seen as a practical activity that literally takes place and intervenes within specific contexts. Different versions of contextual knowledge circulate, but what generally connects them is a rather modest attitude towards the powers of theory (cf. Thrift, 1996). Theories are of course vital and indispensable accounts, but at the same time they are always limited and partial: they are marked by the contexts from which they emerge and the circumstances that they are intended to meet.

Common to contextual approaches is their reference to dynamic, connected time–spaces. More recent contributions both accentuate and develop this point. Schatzski (2002), for example, in what he calls a ‘site ontology’, connects to practice and human coexistence. Social sites, in this account, are contexts where ‘practices and orders form an immense, shifting, and transmogrifying mesh in which they overlap, interweave, cohere, conflict, diverge, scatter and enable as well as constrain each other’. In another way, Massey (2005), without using the term, opens to a radically dynamic vision of contextuality. She discusses space in terms of interrelations, heterogeneity and process, and connects it to time through a double determination as ‘discrete multiplicity’ and ‘dynamic simultaneity’. This allows for a conception of different time–spaces (or contexts) as relational; as ever-shifting constellations of trajectories, constructed out of their interrelations and ‘throwntogetherness’. contiguous zone A zone of special jurisdictional purposes contiguous to the territorial sea, which a coastal state may claim up to 24 nautical miles from the baseline for measuring the territorial sea. The coastal state may, in such a zone, exercise the control necessary to: (1) prevent infringement of its customs, fiscal, immigration or sanitary laws and regulations within its territory or territorial sea; and (2) punish infringement of such laws and regulations committed within its territory and territorial sea (United Nations, 1983, Art. 33). This enables foreign nationals to exercise numerous prerogatives, including rights of navigation, overflying, fishing, conducting research and laying submarine cables. sch

continental shelf The Third United Nations Conference on the Law of the Sea (UNCLOS III) defines the continental shelf as ‘the natural prolongation of the land territory to the outer edge of the continental margin, or to a distance of 200 nautical miles from the baselines from which the breadth of the territorial sea is measured’ (United Nations, 1983, Art. 76). Where the continental margin extends beyond 200 nautical miles from the baseline, the coastal state must establish its outer edge with the highly technical methods stipulated in Article 76 of the Convention. The coastal state exercises over the continental shelf ‘sovereign rights for the purpose of exploring it and exploiting its natural resources’ (United Nations, 1983, Art. 77). sch

continents Usually defined as ‘large, continuous, discrete masses of land’, the identification of continents is both conventional and contingent, because it is closely bound up with the histories of exploration, geography and geopolitics. Contemporaries divided the Graeco-Roman world into three continents – Europe, Asia and Libya (see Africa) – but as early as the fifth century bce Herodotus was puzzled ‘why three distinct women’s names should be given to what is really a single landmass’ (Lewis and Wigen, 1997, p. 22). In medieval Europe, cosmographers and cartographers retained this tripartite division but saw the three as parts of a single ‘world island’, or Orbis Terrarum. The European ‘discovery’ of the Americas from the late fifteenth century followed by the Great Southern Continent of Australia in the early seventeenth century.
displaced these ETHNOCENTRISMS and allowed for a heightened sense of global division and distinction.

In English, the word ‘continent’ was not used to denote major divisions of the GLOBE until the early seventeenth century. In the course of the eighteenth and nineteenth centuries, those differences were calcified by doctrines of ENVIRONMENTAL DETERMINISM: the continents were distinguished by the supposedly intimate, and even causal, connections between their physical and human geographies. The categories of the emergent ‘continental system’ were thus naturalized, ‘coming to be regarded not as products of a fallible human imagination but as real entities that had been “discovered” through empirical inquiry’ (Lewis and Wigen, 1977, p. 30).

The arbitrary nature of the continental schema is revealed by the different systems in contemporary use (see table), but while these have little or no scientific merit they nonetheless often retain considerable popular and geopolitical significance. (See also META-GEOGRAPHY.)

**Contrapuntal geographies** The NETWORKS through which people and events in different places around the world are connected in a complex, dynamic and uneven web that **both** maintains their specificity and mobilizes their interactions. Contrapuntal geographies thus reject two conventional prejudices: the uniqueness of PLACE and the universality of SPACE. Places are not closed and self-sufficient, but neither is (global) space open and increasingly self-similar. The term derives from the work of Edward Said (1935–2003), a literary critic with a lively GEOGRAPHICAL IMAGINATION. He regarded ‘contrapuntal reading’ as an indispensable part of cultural critique, and particularly of the critique of COLONIALISM. Said argued that EUROPE – and the ‘WEST’ more generally – relied on a myth of auto-genesis (self-production) that represented MODERNITY as the unique product of the actions of Europeans, who then had both the right and the responsibility to reach out to bring to others the fruits of progress that would otherwise be beyond their grasp. He objected to this not only for its narcissism but also for its ESSENTIALISM: in his view, all cultures are hybrids, ‘contrapuntal ensembles’. This was partly a matter of material fact – networks of commodity exchange, of MIGRATION and the like – and partly a matter of cultural construction: ‘No IDENTITY can ever exist by itself and without an array of opposites, negatives, oppositions’ (Said, 1993, p. 58: see also IMAGINATIVE GEOGRAPHIES). It was therefore essential to bring these ‘overlapping territories [and] intertwined histories’ together.

Said was an accomplished musician and his root METAPHOR was a musical one: ‘In the counterpoint of Western classical music, various themes play off one another, with only a provisional privilege being given to any particular one; yet in the resulting polyphony there is concert and order, an organized interplay that derives from the themes, not from a rigorous melodic or formal principle outside the work. In the same way, I believe, we can read and interpret English novels . . .’ (Said, 1993, p. 51). There are three crucial points about such a project as it spirals beyond literary criticism:

1. Contrapuntal geographies are rarely transparent and their disclosure requires both theoretical and analytical acuity. Another literary critic, Frederic Jameson, regarded contrapuntal reading as vital to the interpretation of the colonial world by virtue of ‘the systematic occultation of colony from metropolis’ but argued that GLOBALIZATION has produced an ‘epistemological transparency’. This is precisely the universality rejected by Said’s conception (cf. Gregory, 2004b, pp. 11–12).

2. Contrapuntal geographies may disclose ‘concert and order’, but this must not be mistaken for harmony or equilibrium: their movements are orchestrated through differential relations of POWER (see also TRANSCULTURATION). Said’s (1993, p. 279) own account focused on a particular modality of power, by seeing ‘Western and non-Western experiences as belonging together because they are connected by imperialism’.

Third, contrapuntal geographies require reading from multiple sites and points of view: not only from the point of view of the dominant discourse but also from the perspective of subaltern knowledges (cf. Featherstone, 2005a: see also subaltern studies).

Contrapuntal geographies have been invoked to wire the discourse of terrorism and security mobilized by the USA in its ‘war on terror’ in Afghanistan and Iraq to heightened Israeli military action in occupied Palestine (Gregory, 2004) and to campaigns by the Hindu Right against Muslims in India (Oza, 2007): like Said’s original proposal, both studies revealed the reactivation of colonial tropes to characterize ‘the common enemy’.

Other projects have been directed towards similar ends without invoking Said: Gilroy’s (1993) ‘Black Atlantic’ is one, particularly prominent example of a transnational spatial formation composed through an intricate interplay of connection and difference. Said himself preferred demonstration to theoretical elaboration, but in human geography there have been several attempts to develop a more insistently materialist theorization of these ideas. Thus Katz (2001a) substituted a cartographic metaphor—a countertopography—for Said’s musical one:

I want to imagine a politics that maintains the distinctiveness of a place while recognizing that it is connected analytically to other places along contour lines that represent not elevation but particular relations to a process (e.g. globalizing capitalist relations of production). This offers a multifaceted way of theorizing the connectedness of vastly different places made artificially discrete by virtue of history and geography but which also reproduce themselves differently amidst the common political-economic and socio-cultural processes they experience. This notion of topography involves a particular precision and specificity that connects distant places and in so doing enables the inference of connection in uncharted places in between … Such connections are precise analytical relationships not homogenizations. Not all places affected by capital’s global ambition are affected the same way … The larger intent is to produce countertopographies that link different places analytically and thereby enhance struggles in the name of common interests. (Katz, 2001a, pp. 1229–30)

These geographies are in constant and often disjunctive motion, and Sheppard (2002) borrowed the concept of a wormhole from relativity theory to accentuate the complex topologies involved:

The positionalities of two places should be measured not by the physical distance separating them, but by the intensity and nature of their interconnectedness … Like networks, wormholes leapfrog across space, creating topological connections that reduce the separation between distant places and reshape their positionalities … Wormholes are a structural effect of the long historical geography of globalization, reflective of how globalization processes reshape space/time. The existence of such wormholes may also have highly asymmetric consequences for the places that are connected …’ (Sheppard, 2002, pp. 323–4)

Whatever vocabulary is preferred, however, mapping these volatile geographies involves more than a cartography of connections: the implication of differentials and differences in time-space is vital (cf. power-geometry). And Said’s original metaphor conveys an equally crucial sense of dynamics: of movement, variation and change.

conurbation A term coined by Patrick Geddes (1854–1932) to describe a built-up area created through the coalescence of two or more once-separate settlements, probably initiated through ribbon development along the main inter-urban routes. With greater urban sprawl the term has largely been replaced by terms such as megalopolis, metropolitan area and metropolitan labour area, in which the built-up area may be discontinuous.

convergence, regional The tendency for regional incomes or levels of living within a country to become more equal over time. That this should be the case is a prediction derived from neo-classical economics, which portrays labour, capital and other factors of production moving from one region to another seeking the best possible returns (in the form of wages or profits), until there is nothing to gain from further movement because returns are the same in all regions. Thus a competitive free-market economy under capitalism should tend towards regional equality, subject to constraints on the spatial mobility of factors of production.
Evidence for individual nations shows that this prediction does not necessarily hold true. For example, regional incomes in the USA show steady convergence from the latter part of the nineteenth century up to the 1970s. However, individual regions had their own trajectory, reflecting their historical experience of greater or lesser movement towards the national average income, which complicates a simple picture of regular convergence. In addition, the convergence thesis depends on the geographical scale adopted: the trend towards reduced inequality at a broad regional scale can be contradicted more locally; for example, between Core and Periphery and within the city. Thus in the USA convergence at a broad regional scale has been accompanied by local divergence between city and countryside and among neighbourhoods.

Regional convergence is not confined to capitalist economies and, indeed, may be more marked under a Socialist system that has the equalization of regional living standards as an explicit objective. For example, a strong convergence tendency could be observed among the republics of the former Soviet Union, although this may have been reversed during the so-called ‘era of stagnation’ that preceded perestroika and the eventual collapse of Communism.

There is evidence also of reversals of convergence in the capitalist world, including the USA, with inter-regional inequality increasing since the 1970s. In the UK, divergence can be observed among regions since the early 1980s, in GDP per capita and other measures of income. The fact that this has occurred during an era of dedication to the free market suggests limits to the extent of regional convergence towards perfect equality under capitalism, in practice if not in theory. Indeed, the earlier era of more positive regional planning may have taken the country further in the direction of equality than would have been the case under less restrained market forces. This suggests that, after a certain level in the convergence process has been reached, state intervention in the form of Regional Policy is a necessary if not sufficient condition for further convergence.

co-operative An enterprise formed by an association of members with the aim of promoting their common economic interests. Historically, co-operatives have formed to enhance the selling power of independent, family-based producers; thus they have been most prevalent in the farming sector (Moran, Blundern and Bradley, 1996). Sellers’ co-operatives share market and pricing information, and may act as a single seller to secure better prices. The co-operative form has also been used to enhance purchasing power (bulk purchases) and to share the costs of food processing. In recent years, producer co-operatives have formed hand in glove with Fair Trade initiatives to improve the working conditions and income of peasant producers.

core–periphery model A model of systematic patterns of uneven development in the geography of human activity, based on uneven distribution of power within and between societies. Cores and peripheries can be analysed at a variety of geographic scales, including uneven regional development within national economies and uneven development at a global scale.

The development of cores and peripheries within national economies was a topic of considerable concern to national development planners and urban and regional geographers in the early post-Second World War period. Particularly in developing countries, unbalanced growth between dominant, typically highly primate, urban centres and agrarian regions of the country led to a variety of exercises in promoting regional and secondary city development (see dual economy). However, the strength of existing economic cores and the failure of many decentralization projects has led in recent decades to less enthusiasm for state policies that attempt to overcome core–periphery structures at a national level, while uneven development is increasingly seen as central to the dynamics of capitalism (Smith, 2008 [1984]).

The notion of cores and peripheries at a global scale is associated with the work of a variety of development economists, but has been an especially pronounced feature of approaches such as dependency theory (Frank, 1967) and world-systems analysis (Wallerstein, 1979). Assessments of core–periphery dynamics at a global scale have typically taken national states and economies as important constituents of the global system, and have thus identified some states as being part of the global core and others as part of the...
global periphery. Core states are those with the highest value-added industrial manufacturing and service sectors, while peripheral states are more dependent on agricultural and raw materials exports – and, more recently, on lower value-added manufactured goods. WORLD-SYSTEMS theorists identify states that are semi-peripheral in that their exports comprise a mix of higher and lower value-added goods (Wallerstein, 1979, pp. 66–94).

Many core–periphery models, such as that of Andre Gunder Frank, connect core–periphery structures at a national scale with the global core–periphery structure (Frank, 1967, pp. 8220). In particular, such models have seen primate cities in developing countries as nodal points connecting national economies to the global system, and as ‘suction pumps’ from which surplus is siphoned out of peripheral societies and into global circuits of CAPITAL (Armstrong and McGee, 1985). Recent processes of GLOBALIZATION have called into question the degree of coherence of national political economies, making the variants of core–periphery theory that hinge on a hierarchy of states more problematic. But the models that emphasize crucial roles for cities in the developing world retain considerable relevance.

Suggested reading

**corporatization** The spread of business objectives, methods and DISCOURSES into the non-profit and STATE sectors of SOCIETY. Schools and universities, hospitals, welfare offices and so on are increasingly held to the operating standards of private enterprise, despite differing reasons for their existence, resources and relationship to SOCIETY. Talk of ‘cost centres’, ‘customers’, ‘products’, ‘markets’ and even ‘profitability’ (in relation, for example, to university spin-offs of private companies) grows more common. Non-business organizations should strive for efficiency and respond to changing social needs. But the meaning of efficiency and responsiveness in these organizations ought perhaps to be evaluated on different grounds than we would apply to a corporation.

Steck (2003).

**correlation** The degree of association between two or more variables. In statistical analyses, correlation coefficients varying between +/−1.0 are measures of the goodness-of-fit of a relationship: a value of 1.0 indicates a perfect relationship. If values less than 1.0 are squared, they indicate the proportion of the variation in one variable than can be accounted for statistically by the other(s): a correlation of 0.8 indicates that 0.64 of the variation can be accounted for. Positive correlations indicate that as one variable increases in value, so does the other: negative correlations that as one increases in value, the other decreases. In several variants of the GENERAL LINEAR MODEL, notably REGRESSION analysis, the correlation between two variables is denoted by $r$ and the (multiple) correlation among three or more variables by $R$. A correlation coefficient is merely an indicator of covariation among two or more variables and is not a measure of causality, although a high correlation may have important theoretical implications.

**cosmography** The unified study of the Earth in relation to the heavens, cosmography arises from geocentric assumptions and a belief in homologies between the spatial order of terrestrial and celestial spheres. The spherical geometry of celestial poles, great circles, hemispheres and ecliptic can be projected on to both Earth and sky and illustrated by the armillary sphere, whose spherical lattice of the five great circles, poles, axis and colures makes it the symbol of cosmographic science (still to be found on the flag of Portugal). Mathematical cosmography had practical significance for oceanic navigation, and early in modern EUROPE cosmographers were often influential court appointees (Fiorani, 2005). Cosmographic order has given rise in many belief systems to ideas of divinely ordered, cosmic harmony, reproduced at varying SCALES, including the human microcosm, and to attempts to steer influences believed to flow through the cosmos, often by manipulating cosmographic diagrams and images. Descriptive cosmography was the classification and description of the contents of the created cosmos, assumed to have an order that reflected mathematical relations. Incorporating both the mathematics of order and description of contents, cosmography eludes easy definition and courts intellectual incoherence.

Cosmographic science peaked in early modern Europe, where cosmographies took the form of illustrated books and maps that may be regarded as precursors of the modern atlas. Cosmographies became increasingly encyclopaedic in seeking to systematize spatially and
illustrate the whole of universal knowledge. The dazzling 'marvels' of the worlds newly encountered by Renaissance Europeans meant that cosmography often failed to distinguish reality from fable, and the cosmographic project's grand synthetic goals became increasingly unwieldy (Grafton, 1992; Lestringant, 1994). Cosmography's assumption of a closed universe meant that acceptance of Copernicus' world system, especially after Galileo and Newton, led to its decline as an active field of knowledge, being replaced by astronomy and geography as distinct enquiries (see also GEOGRAPHY, HISTORY OF), although mathematical cosmography remained a critical science during the eighteenth-century establishment of accurate meridians on an oblate globe and the development of geodetic survey (Edney, 1993). Non-Western and pre-modern cosmologies find graphic expression in diverse cosmographic maps and diagrams (see CARTOGRAPHY, HISTORY OF).

cosmopolitanism Across the centuries, political philosophers and social commentators have argued over the desirability and possibility of social organization and affiliation on a cosmopolitan scale. Cosmopolitans, blaming NATIONALISM for many of the ills of the world, have argued that universal attachments and RIGHTS offered at transnational SCALE are desirable for human progress and emancipation. For example, the ancient Greeks emphasized the global responsibility of the citizen, while during much of modernity the cosmopolitan ideal has been driven by Kant's desire for governments to have obligations beyond their own TERRITORIES (Delanty, 2005b). In contrast, Adam Smith stressed the role of sympathy as a bridge between individuals and among nations in a world differentiated by MARKET laws, and the French revolution sought to extend the principles of liberty, equality and fraternity as universal values, while Marx insisted on the necessity of a socialist commons under the guidance of the international workers' movement.

In recent years, the cosmopolitan ideal has evolved in new directions, to include proposals such as global government, binding international charters, corporate social responsibility, enhanced HUMAN RIGHTS, global environmental stewardship and various international commitments to poor countries, as a response to growing international inequality and planetary damage (Held and Koenig-Archibugi, 2003). Global CITIZENSHIP and political action in general has come to be placed at the heart of the cosmopolitan ideal as a necessary adjunct to the process of GLOBALIZATION in economic, social, institutional and cultural life, involving the rise of planetary organization, transnational flows and cross-national interdependencies. Global citizenship and global government are seen to be required by the rise of global society.

The critics of cosmopolitanism have long argued, however, that collective AFFECT and affiliation have always depended on strong territorial loyalty and identification, as have the processes and institutions of political expression and action, most commonly around ethno-national communities. Thus, cosmopolitan ideals have been judged to be elitist, as reflections of only the values and cultural practices of intellectuals, the itinerant upper echelons and territorially disaffected minorities, with mass or majority affiliation held to be gathered around enduring national and local communities. The critics – past and present – have also dismissed the cosmopolitan ideal as utopian, naïve or unworkable, on the grounds that it is a fictive aspiration that fails to excite affect and loyalty on the ground, that in a world ordered around local, national and regional SOVEREIGNTY its institutional proposals have little chance of uptake and survival, and that as a symbol of progress it is undermined by a human condition that is increasingly wary of universalistic or teleological aspirations (Bauman, 2003).

Undercutting these normative disputes, lies the claim that contemporary social reality is becoming thoroughly cosmopolitan, regardless of questions of consciousness. Ulrich Beck (2004), for example, stresses the need to distinguish cosmopolitanism as a credo from cosmopolitanization as a multidimensional process of trans-territorial transformation that demands more than national or STATE-centred response. Beck provides four examples. The first is 'risk cosmopolitanism', a fear shared by all around the world of heightened RISK – military, climatic, epidemiological, environmental, sociobiological – viewed as a global threat that requires new commonalities and interconnected action. Consequently, the second is a 'postnational politics' driven by a global sense of unlimited threats and uncertainties that are much harder to identify and calculate on the basis of traditional state measures, forcing new approaches to inter-state regulation and the rise of many non-state policy networks. The third example he gives is the globalization
of inequality as a consequence of entangled national and transnational processes (from state welfare decisions to global neo-liberalism and the acts of transnational corporations and financial institutions); a phenomenon requiring transnational interventions, but all too frequently treated by national elites as a domestic issue (see also transnationalism). Finally, Beck refers to ‘banal cosmopolitanism’ based around the everyday consumption of products and images from around the world, and the increasing formation of cultural practices and affiliations through world engagement.

The sum of these few examples of a multi-dimensional process is the claim that ‘the experiential space of separate national societies, each with its own uniform language, identity and politics, is becoming more and more of a myth’, as what counts as national becomes ‘in its essence increasingly transnational or cosmopolitan’ (Beck, 2004, p. 153). This does not in any way mean that we are all becoming cosmopolitans, but it does question how far accounts of what goes on within nations can afford to ignore the world at large. These considerations have prompted some geographers to revisit the history of geography (see geography, history of), not to condemn its contributions tout court but to offer nuanced readings of its engagement with cosmopolitan ideals (Cosgrove, 2003; cf. Harvey 2000a), while others have sought to energize the contemporary project of a critical human geography by reflecting on the implications of cosmopolitanism for ethics (e.g. Popke, 2007) and for political action (e.g. Gidwani, 2006).

**cost structure** The division of the total cost of production into its constituent parts, or the cost of individual inputs. For example, the cost structure of the iron and steel industry would indicate absolute (or relative) amounts of expenditure on iron ore, coking coal, limestone, labour, capital equipment and so on.

The cost structure thus reveals whether a particular activity is material intensive, capital intensive, labour intensive and so on, with respect to expenditure on inputs. This information can provide an initial clue to the inputs likely to have the greatest bearing on the location of the activity in question.

**cost–benefit analysis** An analytical procedure for the comprehensive, frequently ex ante, economic evaluation of major public-sector projects, embracing their full positive and negative societal consequences, sometimes over the range of project options and geographical scales (e.g. Turner, Adger and Doktor, 1995). As such, cost–benefit analysis (commonly ‘CBA’) covers a wider range of considerations than the profit-and-loss accounting of private-sector decision-making. Originally applied to public river and harbour projects in the USA, CBA’s contemporary uses extend to such diverse issues as urban air quality, dam and irrigation schemes, refuse recycling, medical and veterinary procedures, transport deregulation, roadway maintenance, disposal of hazardous waste, energy generating and conservation and job creation schemes (Armstrong and Taylor, 2000; see also Mishan and Quah, 2007).

Cost–benefit analysis involves three stages. First, costs and benefits associated with public projects have to be identified, including intangible externalities such as noise, habitat loss, pollution and raising human health and lifespans. Second, these must be quantified, including their discounting to a common base date, since the various costs and benefits can arise over very different time periods. Finally, the resulting cost–benefit ratios are incorporated into the decision-making, or project-evaluation, stage, alongside political and other judgmental inputs (Turner, 2007).

Economists differ as to the best application of these general principles in particular cases, and over the validity of the exercise as a whole. Defining all costs and benefits is one such: how to be comprehensive without double-counting. Not all variables have an obvious market value, and some ‘estimates’ may be little more than guesses. The discount rate can also be crucial to the outcome, and endangers undervaluing the welfare of future generations. Finally, distributional issues are important – a $1 million benefit to poor residents from one freeway route should outweigh the same gain to rich citizens from an alternative.

Recent extensions of cost–benefit analysis to large-scale environmental issues, such as global warming, are now at the forefront of international debate (Stern, 2007) but have proved particularly controversial. Not only are such potential environmental changes irreversible, but the cost and benefits vary internationally, raise sharp ethical valuation judgements (e.g. over landscape, wildlife and human life) and questions of inter- and intra-generational fairness – the already poor are likely to suffer most, while the future generations who feel the sharp end of global
changes may also have the technology to combat them. AGH

counterfactuals Literally contrary to the facts: determining what might have been had the facts been different. What if the Rhine River never existed? What if in Florida in November 2000, fewer chads were left hanging? And, perish the thought, what if The dictionary of human geography had never been written? Posed as subjunctive conditional, counterfactuals focus attention on comparing the known case, the historical geographical record, with what might have been the case in a different possible world. Discussions of counterfactuals are found in PHILOSOPHY, social psychology, political science, some branches of economics and perhaps most prominently in history (and through it, HISTORICAL GEOGRAPHY). Also termed virtual history, historians use counterfactuals to facilitate clearer explanation of past events. For example, to understand the rise of German Nazism, Ferguson (1998) imagines twentieth-century Europe without the First World War. On that basis, he cannot conceive of the emergence of the Third Reich, and so concludes that the First World War must be its cause. For a number of historians, however, this is not history, but a form of fiction. The economic historian M.M. Postan declared that ‘the might-have-beens of history are not a profitable subject for discussion’ (quoted in Gould, 1969, p. 195). With POSTMODERN and POST-STRUCTURAL scepticism about the separation of fact and fiction, this kind of objection is less convincing, and virtual histories burgeon both in academia and in literature (Ferguson, 1999). counter-urbanization Population deconcentration away from large urban areas and their SUBURBS, first identified in the USA in the 1970s, where many metropolitan areas were losing population through net MIGRATION to non-metropolitan areas. The growing areas were generally relatively small settlements, which were either increasingly accessible for commuting or offered attractive environments for retirees and home-based workers. This changing population distribution was paralleled by employment deconcentration to smaller towns that offered cheaper, more extensive tracts of land, more plant (usually non-unionized) labour forces, plus pleasant environments and were more accessible as TRANSPORT COSTS were reduced both absolutely and relatively (cf. FOOTLOOSE INDUSTRY). Similar patterns of counter-urbanization were identified in many other countries in the late twentieth century, though there has been some ‘BACK-TO-THE CITY’ recently, which has made the patterns of change less clear-cut. creative destruction The general notion that only through the demise of existing entities can new ones be brought into the world. While associated with thinkers such as Nietzsche and Hegel, creative destruction as a distinct phrase is best known to geographical audiences through the work of the economist Joseph Schumpeter. In his hands, it is both a description of CAPITALISM’s disequilibrium dynamics and a historical argument regarding the passage to social democratic WELFARE STATES. Against the marginalist concerns of twentieth-century NEO-CLASSICAL ECONOMICS, Schumpeter (1942) took up macro-economic questions in the classical tradition (see POLITICAL ECONOMY). He argued that capitalist competition induces entrepreneurs to innovate (and to maintain a stable of scientists for the purpose), resulting in qualitative changes to production technologies that are fundamentally disruptive to the existing economic landscape. As opposed to the smooth unfolding of technological INNOVATION, the equilibrium provided by the market’s ‘hidden hand’, and theories of disruption caused by exogenous forces (e.g. weather, war), Schumpeter saw capitalism as inherently unstable, a condition that its citizens would ultimately find intolerable. Schumpeter’s ideas are often likened to those of Marx, important differences being that the latter desired capitalism’s demise and located its chronic instability less in competition than in ACCUMULATION as such (CLASS-based extraction and investment of surplus value: see Storper and Walker, 1989). It is, of course, in the spirit of the latter that Harvey so often invokes ‘creative destruction’ in his construction of an explicitly historico-geographical materialism and his critical analyses of LANDSCAPES of capital accumulation (see, e.g., Harvey, 1989b: see also MARXIST GEOGRAPHY). GHe
crime  The geographical study of crime seeks to: explain the spatial clustering of criminal behaviour; consider how the construction and monitoring of spaces might reduce the incidence of criminality; and explain how wider social and political dynamics shape the fear of crime and societal responses to it.

Like many other social phenomena, criminal behaviour is unevenly distributed. Much work in GEOGRAPHY attempts to account for this variation, typically by elaborating the demographic characteristics and common social patterns in places where crime is concentrated. Often taking inspiration from the ‘social disorganization’ theory developed by CHICAGO SCHOOL sociologists, these accounts take aim at several factors arguably common to places characterized by concentrated disadvantage: the comparative lack of economic opportunity, the likelihood of high residential mobility, the high percentage of single-parent households, and the general cultural acceptance of crime (Smith, S.J., 1986a; Sampson, Raudenbush and Earl, 1997). Some geographical work focuses more on the common practices of criminal offenders, and how their time-space patterns make opportunities for crime more or less available to them (Rengert, 1997). A related, and highly popular, criminology of place concentrates on the alleged effects of so-called ‘broken windows’ as incubators of crime. Places where broken windows are not fixed signify a lack of informal social control that invites the criminally minded into their midst (Wilson and Kelling, 1982; for a critique, see Harcourt, 2001). In recent years, the geographical clustering of crime has been mapped by police departments using GEOGRAPHIC INFORMATION SYSTEMS (GIS) technologies: these help isolate ‘hot spots’ of criminality for targeted enforcement.

For some, this clustering of ‘hot spots’ is connected to the built environment. Various related approaches – ‘situational crime prevention’, ‘defensible space’, ‘environmental criminology’ – suggest that crime’s geographies are significantly a consequence of whether spaces deter crime through effective defensibility and SURVEILLANCE. Places can thus be constructed to repel crime if they make entry difficult or monitoring easy. Such monitoring takes conspicuous form in the UK, and increasingly in other places, through closed-circuit television (CCTV) units that monitor much of public space (Fyfe and Bannister, 1998). These surveillance practices ostensibly reduce criminality by increasing the threat of capture.

Other work in the geography of crime focuses on how crime is commonly constructed, socially and politically. There is now, for instance, an extensive literature on the fear of crime, and its variation across social groups and across space (see Koskela and Pain, 2000). Such fear is more prevalent amongst the elderly and amongst females, especially when they are in unfamiliar public places. Fear of crime is also a political construct, used as a means to legitimate ‘get tough’ policies for reducing crime. These political processes are sometimes tied to the wider practices of NEO-LIBERALISM, through which welfarist approaches to social problems are delegitimized, in favour of policies that emphasize social control.

crisis  A potentially complete failure in the reproduction of systemic relations. The term appears in multiple DISCOURSES, being used to describe threatened failures in the reproduction of socio-economic structures, political institutions, representational conventions, ecological systems and more. Its connotations are largely negative: describing the failure to reproduce relations as a crisis carries some implication that continuity in those relations is desirable or necessary. Crises of social relations are often viewed as having positive aspects as well, though, inasmuch as they present windows of opportunity for progressive change.

Relevant work in HUMAN GEOGRAPHY has focused mainly on crises of capitalism. Human geographers influenced by HISTORICAL MATERIALISM have viewed CAPITALISM as a socio-economic system whose internal contradictions make it inherently unstable and prone to periodic crises that lead to the reconfiguration and greater socialization of relations of production and reproduction. Such a trajectory ultimately calls into question the reproduction of capitalism itself, making this perspective fundamentally different from more mainstream accounts of the ‘business cycle’. Briefly, capitalism is prone to crisis because its endogenous dynamics frequently and characteristically produce situations in which: (i) workers, collectively, cannot afford to buy the COMMODITIES they produce (a crisis of underconsumption); (ii) more commodities are produced than can be absorbed by all available purchasing power (a crisis of overproduction); (iii) capitalists accumulate more capital than they can invest in profitable
enterprises (a crisis of over-accumulation); or (iv) a large portion of the total labour force cannot be profitably employed in the production of commodities (a crisis of unemployment or underemployment). These various manifestations of crisis are closely related, with one often leading to or accompanying another.

Human geographers, most prominently David Harvey, have built upon and refined Marx’s original work to develop a more coherent and geographical theory of the dynamics of capitalist crises. In work central to Marxist geography, Harvey (1999 [1982]) has proposed a threefold theory of capitalist crises. His ‘first cut’ explains how the crisis tendencies above are inherent to capitalism. His ‘second cut’ focuses on their temporal displacement via fiscal and monetary arrangements that stave off crises by laying the seeds of larger problems in the future (e.g. increased household reliance on credit cards, or ballooning national deficits). His ‘third cut’ explores the ways in which geography can be used to combat crisis tendencies (see also Harvey, 2001); for example, by massive investments in new locations or the opening of new markets, and suggests that crises of capital accumulation are culturally mirrored in crises of representation that materially affect the ways in which time and space are constructed and construed (Harvey, 1989b) (see figure: see also time-space compression). The state plays critical roles in the above processes. Collectively, these theoretical refinements help to explain how capitalism has survived and expanded despite regular crises, contrary to the predictions of classical Marxism. Similar questions have been taken up in regulation theory, which explores the role of minimally necessary fits between narrowly ‘economic’ activities (regimes of accumulation) and broader social and political conventions and institutions (modes of regulation) in producing and overcoming periodic crises (Walker, 1995). Meanwhile, ecological Marxism has sought to bring nature into crisis theory, pointing out that severe environmental degradation and other failures of environmental regulation may both precipitate a crisis, and be important objects of political struggle during one (O’Connor, 1998). critical geopolitics The emergence of critical geopolitics within political geography situates power not in the hands of a sovereign state or individual, but in more relational ways that traverse a spectrum of scales of social life. Influenced by post-structuralism and responding to the realist approaches of international relations in conventional geopolitical discourse, critical geopolitics has not simply contested the claims of international relations (IR) theory and international political economy (IPE), but taken them apart by exposing the assumptions of each and challenging the taken-for-granted categories of analysis within IR in particular. Drawing inspiration from the work of Michel Foucault, Jacques Derrida and Gayatri Spivak, critical geopolitics is a less a theory of how space and politics intersect than a deconstruction – of the normalized categories and narratives of conventional geopolitics. Such an approach challenges seemingly commonsense understandings and practices of ‘peace’, ‘violence’ and ‘war’ within the state system (Dalby, 1991).

Critical geopolitics is defined by its deconstructive impulse (see deconstruction),
questioning assumptions in a taken-for-granted world and examining the institutional modes of producing such a world vis-à-vis writing about the world, its geography and politics. Such an approach does not subscribe to any one mode of apprehending the geopolitical world; it eschews the idea that any geography can be fully finalized or authoritative (Sparker, 2005). Rather, it seeks to reveal and examine the assumptions, constructions and power relations that are foundational to such apprehension (Shapiro, 1997).

A central project for critical geopolitics is analysis of the discursive practices by which scholars spatialize international politics: it asks why and how a particular geopolitical narrative is normalized and accepted (Ó Tuathail, 1996b) (see discourse; cf. Müller, 2008). Critical geopolitics thus seeks to politicize knowledge production through discourse analysis of dominant geopolitical practices, such as foreign policy and techniques of representing war (Shapiro, 1997; Gregory, 2004b). Within geography, ‘[c]ritical geopolitics is one of many cultures of resistance to Geography as imperial truth, state-capitalized knowledge, and military weapon. It is a small part of a much larger rainbow struggle to decolonize our inherited geographical imagination so that other geo-graphings and other worlds might be possible’ (Ó Tuathail, 1996b, p. 256). Sparker (2005, p. xiv) adds that ‘any assumption about geography either as a result of or as a basis or container for other social relations always risks fetishizing a particular spatial arrangement and ignoring ongoing processes of spatial production, negotiation, and contestation’.

Ó Tuathail’s (1996b) agenda-setting call for critical geopolitics was a central text in the unravelling of dominant geopolitical discourse. It provided compelling critiques of geopolitics, but through its distance from alternative epistemological ways of knowing how to ‘geo-graph’ the world (see epistemology) or from ontological commitments to it (see ontology), critical geopolitics risked becoming disembodied critical practice and suffered from ‘a dearth of commentary on the prospects for resistance’ (Sparker, 2000b, p. 378; cf. Routledge, 1996a). Even as he argued against positions that are unmarked, unmediated and transcendent, then, O Tuathail unwittingly became part of this category. How dominant geopolitical scripts can be destabilized and recast to take account of people and places represented as the orientalized Other (see orientalism), for example, or excluded from understandings of security and political economy altogether, represents a major challenge for critical geopolitics. To expose the subjects effaced by realist geopolitics and international relations is a laudable goal, but how might political change be effected once power relations have been exposed?

Sparker (2005) seeks to bridge this gap in his analysis of the ways in which a Canadian organization – the National Action Committee on the Status of Women (NAC) – displaced the masculinist and state-sponsored ‘big picture’ politics through the formation of a counter-public. Sparker’s analysis of the material, political and gendered dimensions of geopolitics employs a feminist politics of location that goes beyond a purely discursive exegesis. Dalby (1994) noted the lack of attention to gender at the intersection of IR theory and critical geopolitics, reiterating important issues that had long been raised by feminists. He examined the ways in which geopolitical categories of security are gendered and the gender-blind analysis of much IR theory. His overview of gender and feminism in IR underscored the broader absence of feminist voices in geopolitics during the 1990s, with notable exceptions (Kofman and Peake, 1990; Kofman, 1996). Since then, conversations between feminist geography and geopolitics have considerably increased, and much of the work that fills these silences is directed towards an explicitly feminist geopolitics (Staeheli, Kofman and Peake, 2004; Hyndman, 2004, 2007).

Critical geopolitics is not limited to the orthodox trinity of gender, race and class. Sharp (2000a) took critical geopolitics in new directions in exploring the underdeveloped connections between politics, popular culture and sexuality, and studies like hers have also extended the engagement of critical geopolitics with the visual rather than narrowly textual (cf. Hughes, 2007; Strüber, 2007). The agenda of critical geopolitics has been further enlarged through explorations of discourses of danger and security (Megoran, 2005), generosity and nationalist identity (Carter, 2006) and affect, fear and emotion (Pain and Smith, 2008). None of these studies is limited to the analysis of discursive effects. These extensions, and others like them, have opened up the field of critical geopolitics and forged a series of connections that involve far more than political geography; critical geopolitical perspectives now reach deep into human geography at large and, as befits their interdisciplinary orientations, across a still wider
interdisciplinary space. It is now difficult to imagine critical analysis of, say, American Empire, Colonialism, Imperialism or Terrorism that does not touch on critical geopolitics at some point. These are vital developments, at once political and intellectual, because they disclose a series of intersections between biopolitics (see Biopower), geopolitics and geo-economics that lie at the heart of the contemporary political moment and that urgently require critical analysis (cf. Sparke, 2007).

**Critical Human Geography** Theoretically informed geographical scholarship, committed to Leftist politics, social justice and liberation through scholarly enquiry. Critical geography is one variant of the rich tradition of critical enquiry in social science and the humanities that embraces Marx’s call not only to interpret the world, but to change it. Fay defines contemporary critical science as the ‘attempt to understand in a rationally responsible manner the oppressive features of a society such that this understanding stimulates its audience to transform their society and thereby liberate themselves’ (1987, p. 4). Agger (1998) identifies several features of critical social theory, as practiced in fields such as Geography. These include: a rejection of positivist enquiry (see positivism); an endorsement of the possibility of progress; a model of society characterized by structural domination produced, in part, through myth and ideology; and a rejection of revolutionary expediency with a concomitant faith in the agency of everyday change and self-transformation.

Critical human geography emerged from a long tradition of dissent. Although its predecessors include the anarchist geography of scholars such as Reclus and Kroptkin (see Anarchism), Anglo-American critical geography’s roots are to be found in the Radical Geography that emerged in the 1970s (see Peet, 2000). A self-identified field of critical geography began to emerge in the late 1980s. Important departures included a rejection of some of the structural excesses of Marxism (in line with a general postmodern turn), and a sharpening interest in questions of culture and representation, as opposed to the economic focus of radical geography. Radical and critical geography, while closely related, are not interchangeable. Some observers (Castree, 2000) worry at the eclipse of the former by the latter.

One important consequence of the postmodern turn has been that critical geography is remarkably varied in its commitments. For Hubbard, Kitchin, Bartley and Fuller (2002), critical geography is diverse in its epistemology, ontology and methodology, and lacks a ‘distinctive theoretical identity’ (p. 62). That said, certain common themes can be discerned (Blomley, 2006). These include:

1. A commitment to social theory and a rejection of empiricism: critical geographers draw from a number of theoretical wells, including political economy, queer theory, post-colonialism and feminism.
2. Self-consciously oppositional enquiry: scholarship that seeks to unmask power, demonstrate inequality, uncover resistance and foster emancipatory politics and social change.
3. An emphasis on representation as a site for domination and resistance: given a general interest in discourse and meaning, one common focus is the ways in which representations of space serve to sustain power (or conversely, can be used to challenge power).
4. An optimistic faith in the power of critical scholarship: critical geography can both undo oppressive forms of social power, and provide transformative insights. In speaking truth to power, in other words, the scholar can undo domination, and free the oppressed: ‘Dissentient thoughts and norm-challenging information can, as history shows, be as potent as armies given the right conditions’, Castree and Wright (2005, p. 2) argue.
5. A commitment to progressive praxis: critical geographers claim common-cause with movements committed to social justice. The precise nature of the relation, and the appropriate focus for, and locus of, activism has been much debated (Fuller and Kitchin, 2004b).
6. Space as a critical tool: a particular attention to the ways in which spatial arrangements and representations can serve to produce inequality and oppression and opposition. To varying degrees, critical geographers note the ways in which space can serve as both a tool and veil of power.

Some important and unresolved questions remain. For example, relatively limited discussion has occurred over the shared commitments, if any, of critical geographers (though cf. Harvey, 2000b). What are geographers critical of? Why? And to what end? To borrow
CRITICAL RATIONALISM

from Barnes (2002), critical geographers are better at the ‘explanatory-diagnostic’ than the ‘anticipatory-utopian’. Critical geography, for Barnes, needs ‘an imaginative capacity to reconfigure the world and our place within it’ (p. 12). This should not entail enforced political conformity, of course. However, too often, the politics that informs critical geography remains implicit and inchoate. More generally, what are the assumptions implicit to critical scholarship? Agger (1998), in a supportive critique of critical social science, raises concerns that it posits a view of human capacity that is predicated on ‘an inflated conception of the powers of human reason and will’ (p. 9).

Another important question concerns the institutionalization of critical geography. While critical geographers like to think of themselves as rebels and outsiders (and were certainly treated as such by the disciplinary establishment fifteen years ago), critical enquiry has become pervasive in geography (Byles, 2001). Critical geography, Castree (2000, p. 958) notes ‘has insinuated itself into the very heart of the discipline’. While this may reflect its analytical strengths and insights, others worry that institutionalization has entailed co-optation. Has critical enquiry lost not only its verve, but also its commitment to political change?

Such charges have come, in part, from critical geographers outside the Anglophone world. For it should be noted that critical geography is practiced (often in distinct ways) across the globe. The particular insights of, for example, Hungarian (Timar, 2003) or Japanese (Mizuoka, Mizuuchi, Hisatake, Tsutsumi and Fujita, 2005) critical geography needs to be better acknowledged (Bialsiewicz, 2003). Better linkages should also be forged with critical scholars in other disciplines.

On this point, the formation of the International Critical Geography group should be noted. This is a loose network of like-minded geographers from Europe, Asia and North America who embrace internationalism and critical enquiry (Desbiens and Smith, 1999). A series of innovative workshops and conferences have been held, beginning with a gathering in Vancouver in 1998.

Suggested reading

critical rationalism A PHILOSOPHY OF SCIENCE developed by Karl Popper (1902–94), asserting the progressive growth in knowledge through continued rational criticism. Nothing should be sacrosanct; everything should be open to scrutiny. While Popper believed that knowledge in the traditional sense of certainty, or justified true belief, was unobtainable, sustained rational criticism would allow us to get ‘nearer to the truth’ (Popper, 1945, vol. 2, p. 237).

Popper ranged enormously in his philosophical interests over a long life, but two are particularly germane for critical rationalism. First, his thesis of FALSIFICATION was developed in opposition to the verifiability principle of LOGICAL POSITIVISM. Verification, Popper argued, required that the truthfulness of a scientific statement be unambiguously proven for every conceivable instance: past, present and future. This could never happen, said Popper (1959). Instead, he proposed that scientific statements are defined by their potential to be falsified. Science advances not by knowing what is true, but by knowing what is false.

Second, we have Popper’s ideas about the growth of human knowledge: he claimed that scientists begin work not with bare facts (again logical positivism’s contention), but with problems to be solved. The starting points are HYPOTHESES, hunches, conjectures about potential solutions and then comparisons with existing theory (Popper, 1963). Should the new conjecture remain unfalsified and possess greater ‘empirical content’ than the old theory, the new should replace the old. By greater empirical content Popper meant the ability of the hypothesis to account for hitherto anomalous results, solve as yet unsolvable problems or make (correct) predictions about phenomena not so far predicted. When Einstein’s theory of relativity was conjectured, for example, it could not be falsified and made correct predictions that went beyond Newton’s old theory. Consequently, the cosmos became Einsteinian, science progressed and human knowledge grew. Behind the latter lay the strategy of critical rationalism: critical in that any theory demonstrably false was eliminated; and rational in that the best theory, the one with the most explanatory force and predictive power, was chosen among those that remained. There was qualified progress, but progress nonetheless.

It is odd that critical rationalism, and Popper’s writings more generally, were only barely taken up in GEOGRAPHY. Popper’s belief in realism, rationality and progress, as well as in the importance of critique, conjecture and scepticism about ultimate truth, were made for the discipline at least in its guise as science during the QUANTITATIVE REVOLUTION. Instead, geographers clung to various forms of
POSITIVISM, the very philosophy that Popper thought he had demolished in 1935. Programmatic statements were made on the behalf of critical rationalism by some geographers including Wilson (1972), one of the key proponents of a scientific approach to geography during the 1960s, and by Bird (1975, 1989), and Chouinard, Fincher and Webber (1984) used Lakatos’ critique and reformulation of Popper’s proposals to outline the conduct of research programmes in a nominally scientific human geography. But critical rationalism was never realized in practice within geography. Indeed, the very idea of such a NORMATIVE philosophical scheme set out in advance to generate scientific progress became increasingly unattractive, especially in the social sciences, after Kuhn’s (1970 [1962]) writings on PARADIGMS, which stressed the messiness of scientific practice and the role of ruptures and revolutions in scientific advance. Further, as human geography moved towards POSTMODERNISM and POST-STRUCTURALISM and their various commitments to anti-REALISM, RELATIVISM and incommensurability, the prospects of Popper’s critical rationalism gaining hold in the discipline became ever more remote.

**critical theory** A primarily European tradition of social and political thought centrally concerned with critical reflection on CAPITALISM and MODERNITY. It is closely associated with the work of the so-called Frankfurt School, which emerged in Germany in the 1920s. The School formed amidst the defeat of left-wing parties in western Europe, the degeneration of the Russian revolution into Soviet Stalinism and the rise of FASCISM. The members of the School expanded classical MARXISM, drawing upon ideas from Freud, Weber and others outside the Marxist tradition, and in particular sought to supplement the orthodox focus on POLITICAL ECONOMY with concepts drawn from the spheres of aesthetics, culture and PHILOSOPHY. Its key members were Theodor Adorno (1903–69), Max Horkheimer (1895–1973) and Herbert Marcuse (1898–1979); another scholar associated with the School, Walter Benjamin (1892–1940), committed suicide fleeing Nazi-occupied France. By then, most members of the School had already moved to the USA, returning to Germany in the 1950s. The key postwar representative of critical theory is Jürgen Habermas (1929–).

Horkheimer (1975) defined critical theory in contrast to traditional theory (the neutral, objective stance claimed in the natural sciences). Unlike traditional theory, critical social theory had to be reflexive and account for its own social origins and purposes. Its attitude was one of distrust towards the social rules and conventions encountered by individuals in their daily lives. The critical theorists identified new trends in capitalism with the emergence of monopolies, the closer association of STATE and capital, the growth of bureaucracy, and the rationalization of social life linked to the dominance of instrumental reason. They explored issues of IDENTITY, authoritarianism, the spread of commodity production, reification and ALIENATION. They were concerned with the way in which CULTURE had become an industry, with popular cultural forms serving to distract workers from the increasingly repetitive nature of their daily work, thus promoting a sense of fatalism and blocking the potential for resistance. Their conclusions on the ideological barriers to revolution in an increasingly one-dimensional society tended to confirm a logic of domination that led to a pessimistic political immobility that they found it difficult to break out of.

Jürgen Habermas has carried on the tradition of critical theory in the postwar period, but has also modified it in important ways. His early work presents a theory of knowledge-constitutive interests (technical, practical and emancipatory) that guide different types of science – empirical-analytical, hermeneutic and critical (Habermas, 1987). Here, critical theory takes on the role of a therapeutic critique, modelled on Freudian PSYCHOANALYTIC THEORY and directed towards freeing society from ideologically distorted perceptions. Problems with this formulation led Habermas to take an important ‘communicative turn’ in the formulation of critical theory in the 1970s (Habermas, 1984, 1987). Social life requires co-operative, communicative interaction and Habermas undertakes the ‘rational reconstruction’ of the underlying system of rules that speakers must master in order to communicate. Speakers uttering a sentence necessarily (though usually implicitly) make certain validity claims (to truth, rightness, sincerity, intelligibility). A genuine rational consensus on the basis of these validity claims can emerge only under conditions of free and unconstrained debate that Habermas
summarizes as 'the ideal speech situation'. This serves as a basis for the critique of ideology as distorted communication and false consensus. Critical theory can thus be shown to be grounded on normative standards that are not arbitrary, but that are inherent in the very structure of language and communication.

Habermas links these ideas to an evolutionary, developmental model of social evolution as a learning process. As societies evolve, 'SYSTEM' (which is to say those areas of social life coordinated through the steering mechanisms of money and power) becomes differentiated and uncoupled from 'LIFEWORLD' (the storehouse of background convictions and world views against which individuals come to a mutual understanding) (see figure). Capitalist modernization can then be criticized as a process of one-sided rationalization, involving the 'colonizing' of the lifeworld through the over-extension of steering mechanisms of markets, bureaucracy and technological rationality.

Habermas sees his work as an attempt to continue the enlightenment tradition in the face of the irrational challenges of postmodernism (Habermas, 1990 [1985]). However, his own views have been criticized for presenting an ethnocentric view of evolution and rationality, and many have found his foundationalist arguments for an 'inherent telos of speech' oriented towards consensus unconvincing.

Others have taken up the challenge posed in his writings in new ways. Thomas McCarthy, for example, is a leading figure in attempts to build links between Habermas' critical theory and elements of American pragmatism. McCarthy's book-length exchange with David Hoy over the relative merits of a critical theory based on the work of Habermas and the genealogical approach of Foucault brings out superbly the relative strengths and weaknesses of the critical theory tradition (Hoy and McCarthy, 1994). Hoy argues that Foucault actually provides an alternative way of continuing the tradition of critical theory by developing an internal, genealogical critique that brings to light the historicity of our reason and self-understanding. In response, McCarthy continues to defend Habermas' aim of constructing a systematic theory of reason and context-transcending truth claims as a necessary basis for critique. This aim also serves to differentiate Habermas' engagement with pragmatism from the more extreme constructivist and ethnocentrist views of Richard Rorty (see Habermas' exchange with Rorty in Brandom, 2000).

Two further caveats are necessary. First, it is obviously the case that this particular tradition of critical theory does not have a monopoly on the concept of 'critical'. Habermas and Popper famously tussled over the critical claims of critical rationalism, for example, while realism asserts its critical potential on the basis of a distinction between surface appearances and underlying, causal mechanisms in a stratified view of reality. Similarly, although the project of a critical human geography has invoked critical theory in the sense discussed here (see Gregory, 1978a, 1994), it is a much more heterodox tradition. In part – and the second caveat – this is because neither Habermas nor his critics have
paid much attention to the spatialities implicit in his formulations. Yet his work is, inevitably, a situated knowledge: his writings have been a response to the dilemmas of postwar Germany seeking to come to terms with the ghosts of its fascist past, and many of his arguments are centred on a particular, even privileged, view of Europe. More than this, however, the colonization of the lifeworld that Habermas claims to identify mirrors, in a radically different register, Lefebvre’s account of the superimposition of abstract space over concrete space (Gregory, 1994: see also production of space), and may be glimpsed in an earlier form in the spatial impress of European colonial systems on the lifeworlds of native peoples (Harris, 1991). Of all those who have been associated with critical theory, however, it has probably been the tragic figure of Benjamin who has left the most enduring mark on human geography: his experimental renderings of the city, in text and as montage, are powerful reminders that modernism was a critique of modernity and not merely a celebration of it, and have inspired conceptual elaborations (e.g. Latham, 1999) and eloquent investigations (e.g. Pred, 1995).

cultural capital A concept coined by the French sociologist Pierre Bourdieu, cultural capital is one among many forms of capital that figure prominently in his intellectual project; namely, to elaborate ‘a general science of the economy of practices’ that would explain the ‘economic logic’ behind apparently non-economic and therefore disinterested practices such as gift exchange or cultural consumption. Cultural capital is closely linked to and functions in conjunction with economic capital (the conventional and most crudely material form of capital that inhabits economic theory) and social capital. The inter-convertibility of various forms of capital is a critical rather than incidental element in Bourdieu’s theory of practice; but Bourdieu is careful to note that the fungibility of cultural and social capital into economic capital is conditional rather than guaranteed, and frequently partial (in short, not without risk). Two additional concepts, symbolic capital and academic capital, which have close affinities with the concept of cultural capital, also appear in Bourdieu’s writings. That said, academic capital may be regarded as a subset of cultural capital and symbolic capital as a superset.

In his instructive treatise, Distinction: a social critique of the judgment of taste (1984), Bourdieu deploys the concept of cultural capital to great effect to show how bourgeois practices of cultural consumption — via the arts, education, cuisine, attire and so on — consolidate an aesthetic that ‘consciously and deliberately or not . . . fulfill[s] a social function of legitimating social differences’. But his clearest discussion of the concept is in a short, often-overlooked essay called ‘The forms of capital’, where Bourdieu identifies three states in which cultural capital can exist: ‘in the embodied state, i.e. in the form of long-lasting dispositions of mind and body; in the objectified state, in the form of cultural goods (pictures, books, dictionaries, instruments, machines, etc.) which are the trace or realization of theories, problematics, etc.; and in the institutionalized state [as educational qualifications]. . .’ (1985, p. 243).

Key aspects of cultural capital differentiate it from economic capital: principal among these are its necessarily embodied form, which makes it both less fungible and less easily acquired than economic capital; and the more overtly social and disguised conditions of its transmission. Economic logic dictates the efficacy of cultural capital: hence, the symbolic profits of distinction (e.g. the ability to read in a society of illiterates) that accrue from cultural capital depend on the scarcity value of that capital, which in turn depends on its distribution within society. The more ill-distributed a particular form of capital, the greater is its value. In a circular argument, Bourdieu maintains that inequalities in the distribution of capital — in short, class divisions — are reproduced intergenerationally by those very forms of capital that demarcate class status in the first instance: ultimately, he writes, ‘the means of appropriating the product of accumulated labor in the objectified state which is held by a given agent [i.e. various forms of capital], depends for its real efficacy on the form of distribution of the means of appropriating the accumulated and objectively available resources . . .’ (1985, pp. 245–6).

cultural ecology An important, if somewhat under-appreciated, precursor to contemporary political ecology. Cultural ecology has been primarily concerned with the relationships among the transformation of nature, social
reproduction and cultural processes within particular social formations. Emerging from North American anthropology in the mid-twentieth century, cultural ecology has mostly concerned itself with non-industrial societies, typically pastoralists, hunter-gathers, fishing cultures and small-scale cultivators, with an emphasis on ethnographic field methods. Cultural ecology in this sense is most closely associated with the work of Julian Steward and the Chicago school, particularly after the publication of Steward’s *Theory of culture change* (1955). Work done or influenced by Steward in this tradition emphasized a close relationship between symbolic culture (values, religious beliefs and traditions) on the one hand, and the material, ecological basis of a society on the other. Steward in particular developed the notion of a ‘cultural core’ shaped in a possibilist sense by the ways in which critical environmental resources (crops, animals, energy sources etc.) were used by a culture. It would be fair to say that Steward’s primary interest was cultural formation and change, but cultural ecology more generally was at the forefront of scholarly attention to questions about the social bases of environmental change, how cultures respond or adapt to environmental change and also how cultures influence the management of critical environmental resources. Moreover, considerable theoretical and methodological diversity characterizes self-described cultural ecologists (Netting, 1986).

As the name would suggest, cultural ecology was heavily influenced by the rise of ecology. This is true not only in terms of a focus on the relationship between environmental conditions and cultural processes, but also in some of the conceptual emphasis on systems, adaptation, homeostasis, resilience, stability and so on, all hallmarks of an earlier phase of ecology (see ecology). It would be unfair to attribute the kind of telos so evident in Clementsian ecology to cultural ecology. But some work in cultural ecology took on a cybernetic character, conveying a sense that all the pieces of a culture meshed into a coherent, smooth-running, well-adapted and stable machine-like whole, with culture functionally linked to environmental conditions and resource availability. This is apparent, for example, in Roy Rappaport’s (1968) work on wild pigs, and the spiritual beliefs and rituals surrounding these resources in New Guinea.

At the same time, strict adherence to traditional ethnography in cultural ecology at times meant that particular social formations were conceptualized rigidly as such, independent and isolated from the rest of the world, with little or no consideration of or facility for the ways in which these ostensibly remote cultures articulate with social processes at broader scales of analysis. This, in turn, meant that cultural ecology provided little capacity for understanding power, the appropriation of surplus and valuation in the context of a global political economy, even when important linkages along these lines were recognized by cultural ecologists themselves (Robbins, 2004). This is a theme articulated well by one of Steward’s students, Eric Wolf (1982), in his argument for the relevance of political economy, and of the need for attention to the articulation of local social formations with broader social processes.

Cultural ecology’s influence goes far beyond localized studies of non-industrial societies, however. As among the first fields to reverse academic specialization, and to seriously consider environmental change within a social science framework, and with an emphasis on careful, empirical observation and analysis, cultural ecology had an important influence in translating and reinforcing environmentalism in the Anglo-American academy. Cultural ecologists in numerous instances have documented the high levels of sophistication and sustainability in many ‘traditional’ settings, questioning the apparent ‘advancement’ of market-guided and/or state-managed resource appropriation (e.g., Geertz, 1963). And some cultural ecologists, before even talk of a first world political ecology, began to apply their approaches in more industrialized settings, with important results (see, e.g., Bayliss-Smith, 1982).

**Cultural economy** In mainstream economics, culture and economy are kept largely apart, in the belief that economic activity follows its own rules and rationality. In contrast, heterodox approaches, tapping deep into the history of classical economics, have long argued that the economy draws on cultural inputs or is culturally embedded. Thus, attention has been drawn, *inter alia*, to such phenomena as the rise of the cultural industries, the role of spectacle, advertising and desire in sustaining consumption, the lubrication of economic relationships by trust and reciprocity, varieties of capitalism explained by differences in national institutional and business cultures, and the role of culturally inflected routines and habits in influencing economic evolution. These various approaches acknowledge the existence of a tight link
between culture and economy, but still continue to treat the two domains as separate entities, arguing that logics governing the two should not be conflated (Ray and Sayer, 1997). Indeed, many writers sympathetic to these approaches insist on the continued primacy of political economy over cultural economy.

More recently, however, a second generation of cultural economy theorization has emerged, one that sees only a singular plane holding together hybrid inputs including abstract rules, historical legacies, symbolic and discursive narratives, social and cultural habits, material arrangements, emotions and aspirations (Callon, 1999; Du Gay and Pryke, 1999; Hetherington and Law, 1999). Still struggling for an exact vocabulary and dispersed across the social sciences, this approach sees economy as a cultural act and culture as an economic act, so that meeting material needs and making a profit or earning a living can be seen as part and parcel of seeking symbolic satisfaction, pleasure and power. Accordingly, in explaining the economics of production, for example, corporate values, workplace cultures, conventions of welfare and rituals of creativity can be shown to shape competitive potential, along with various rules of technological, organizational and market ordering. Similarly, in the economics of markets, rules of value based on price and other forms of rating can be shown to weave in with consumer tastes, the seductions of organized spectacle and the market power of some economic actors.

This variant of the cultural economy approach is marked by a number of conceptual orientations with long histories in classical economic thought (for a synthesis, see Amin and Thrift, 2004). One concerns the absolute centrality of passions in the economy, from the libidinal energies and spectacle of consumption and possession that drive ‘fast capitalism’, through to the love of objects that now so powers wants and needs. A second orientation, which can be traced back to Adam Smith’s emphasis on the role of empathy in making the market economy work, highlights the pivotal significance of moral values, as manifest in the market ethic itself and in the social conventions that justify particular mores of economic behaviour (hedonism, individualism, fast food as bad/good food, trade versus aid). Third, there is new work on the economics of knowledge that recognizes the centrality of creativity based on unconscious neural mobilizations, material cultures and learning-by-doing in small communities of practice. A fourth orientation is to explain generalized trust in ways that supersede the emphasis on interpersonal dynamics found in earlier variants of cultural economy. For example, Seabright (2004) has argued that the option of intimacy among strangers in the market economy, in which multitudes of economic actors who do not know each other constantly jostle, is lubricated by many cultural institutions that have evolved over time, including the facility of laughter. A fifth orientation is to explain economic power less as a force possessed or wielded by some actors and institutions than as a diffuse and subtle form of cultural enrolment, scripted in the standards, rules and accounting measures that daily produce disciplined subjects and regulate economic life, or through particular narratives of what counts as significant in business journals, advertising scripts and stories of corporate prowess. Finally, the cultural-economy approach, following a long lineage of projection from particular situations (e.g. Marx’s projections on capitalist futures based on the British experience) explores the integrative work done by readings of the economy (e.g. Daniel Bell on the service economy or Manuel Castells on the information economy).

This new body of thought, in summary, rethinks the economy as a culturally infused entity, based on the potentialities of passion, moral sentiments, soft knowledge, instituted trust, symptoms of normality and discursive forms of power. These are considered to drive economic life at all levels and manifestations.

cultural geography One of the most rapidly growing and energetic sub-fields in Anglophone geography over the past 20 years. Many have written of a cultural turn in geography paralleling those in other social sciences. Often the subject of controversy over its approaches, claims and methods cultural geography has seen the reinvigoration of some topics and the development of whole new topics of geographic enquiry. Indeed, it may be that we can identify a recent ‘culturalization’ of many branches of geography, rather than simply a field of ‘cultural geography’ – thus, it is not always clear if the field is defined by culture as the content of study, and what its limits might be, or the approach used. There is also a long history of the study of the geography of cultures that has had an
In North American geography, the dominant tradition was the Berkeley School, built around the work of Carl Ortwin Sauer (1889–1975). So powerful was this tradition that around the middle of the twentieth century cultural geography was often used to label all human geography in US universities. Drawing on the work especially of emerging anthropological perspectives on material culture, from the likes of Franz Boas (1858–1942), Sauer added a geographical focus on landscape, drawn from German geography’s work on Landschaft. His most famous formulation on the morphologies of landscape (in his essay of that name in 1925) described the cultural landscape, where culture was the agent and landscape the medium. Work in this tradition charted the origins and diffusion of cultures around the globe from cultural hearths. In this, it tracked the movement mostly via material artefacts, taken as metonyms of cultures in which they were embedded. Some work developed a notion of cultural areas dominated by one cultural group occupying an area. The focus on culture as an agent led to accusations that it was inventing a ‘superorganic’ entity rather than focusing on the mixed, changeable and contested experience of people (Duncan, 1980). Despite its empirical attention to processes of diffusion and change in cultures contacting different environments, it tended to a singular view of culture held by and defining a group.

The focus on the mutual shaping of people and place was echoed in European traditions in cultural geography. The Annales School that developed in France from the work of Paul Vidal de la Blache (1845–1918) is claimed by cultural, and by social and historical geography. It paid close attention to linkage of people and place through ‘genres de vie’; that is, the ways of everyday life. Exemplary works such as Le Roy Ladurie’s (1966) Les Paysans de Languedoc charted the intimate connections of the rhythms of daily life and the environment over the long durée, creating a ‘seamless robe’ of people and place. Vidal de la Blache (1903) summarized this process as follows:

It is man who reveals a country’s individuality by moulding it to his own use. He establishes a connection between unrelated features, substituting for the random effects of local circumstances a systematic cooperation of forces. Only then does a country acquire a specific character, differentiating it from others, till at length it becomes, as it were, a medal struck in the likeness of a people.

The focus was on ordinary folk and everyday cultures rather than high culture. Perhaps the greatest studies building from these traditions, that are still causing controversy, were those of Fernand Braudel (1902–85), whose magisterial works of the shared development of a Mediterranean culture (see Braudel and Reynolds, 1975 [original French 1949]) – based around olives, wine and grain, and the long-term patterns of trade – remain scholarly landmarks. These works echoed the studies of Frédéric le Play (1806–82), who developed a geographical account of France around the categories of place–work–folk. His work was picked up by the British planner and biologist Patrick Geddes, and led to the foundation of the Le Play Society that sponsored a range of geographical expeditions during the mid-twentieth century. They share the vision of groups creating a cultural homeland as ‘an area carved out by axe and plough, which belongs to the people who have carved it out’ (Olwig, 1993, p. 311).

In British geography, a regional approach was inspired by Hettner’s Länderkunde schema (see Hettner, 1907) of natural base up to social and finally cultural superstructure – starting from geology, then topography, climate, natural resources and finally leading to settlement and human culture adapted to those circumstances (Heimatkunde). A similarly choro-logical approach in Swedish geography focused on hembydsforskning (home area studies), and drew upon ethnological studies of material culture and language to...
define cultural regions (Crang, 2000). In Britain, Geddes’ influence produced a regional survey approach that emphasized a visual integration of the landscape as a method of finding unity (Matless, 1992), while the local history work on landscapes of W.G. Hoskins focused on studies that sought to capture the identity and spirit of specific regions through their landscapes.

These classic traditions focused upon the commonalities in the landscape and rural, historical or traditional forms. Criticism of this tendency mounted through the last quarter of the twentieth century. First, HUMANISTIC GEOGRAPHY challenged the lack of concern with, and scope for, individual interpretation and actions. Authors looked at the meaning of places for specific people, and the EMOTIONAL GEOGRAPHIES of cultures found in the bond with specific places and their GENIUS LOCI (e.g. Pocock, 1982). Second, RADICAL, FEMINIST and MARXIST GEOGRAPHY criticized the assumptions of organic wholeness given to cultures, and pointed to the internal divisions, contradictions and conflicts while, moreover, pointing to more contemporary and urban formations. Third, the political context and implications of European traditions has been examined. Thus the work of a German geographer such as Franz Petri, writing between the world wars, examined the spread of Germanic culture from a supposed ancestral cultural hearth around post-Roman Frankish peoples. Based upon an examination of field and PLACE NAMES, taken as indicators of Germanic culture, he could label ‘[t]he character of Frankish settlement in Walloon and Northern France [as] utterly Germanic’ (Ditt, 2001, p. 245) – a highly charged verdict, given the territorial disputes around Germany. This highlights the problematic relationship of artefact to cultures – choosing certain things as indicators of a culture, but leaving other things as analytically insignificant, reveals political dimensions and choices in the analysis.

To these issues was added engagement with other sub-disciplines and fields outside geography, which – in the last two decades of the twentieth century – were also undergoing their own cultural turns. We might, for the sake of argument, characterize the work that followed in two strands, the first tending to respond to developments in social geography and sociology, and the second as drawing from the radical ends of the arts and humanities. Together, they have often been labelled the ‘New Cultural Geography’, which began as something of a rebellion to the above traditions but rapidly swept on to transform other sub-disciplines as well.

The first strand drew on work from BEHAVIOURAL GEOGRAPHY, to which it added the long tradition of ETHNOGRAPHY from the CHICAGO SCHOOL of urban sociology, and arguments over the sociology of culture emerging in the 1970s and through the 1980s. This inspired a rich vein of work on urban cultures and sub-cultures in modern EVERYDAY LIFE. The latter were seen as resistance or TRANSGRESSION, contesting the categories of the majority culture. Culture was no longer seen as somehow a ‘natural’ property of a group but, rather, the medium of power, oppression, contestation and resistance. Much of this work grew from an engagement with the Birmingham Centre for Contemporary Cultural Studies, and worked to look at the role of culture in securing and maintaining the HEGEMONY of dominant groups. It began to push at the cultural construction of social categories (such as age, RACE, CLASS, SEXUALITY or GENDER) and the ways in which these came to signify particular meanings and be connected with specific ways of life (e.g. Bell and Valentine, 1995; Kofman, 1998; Skelton and Valentine, 1998; Pred, 2000).

The second strand of work was differentiated not so much by topic as by method, drawing from the arts and HUMANITIES. Work here drew on critical studies of often high cultural artefacts such as ART and LITERATURE, but moved these techniques to include more popular cultural forms such as FILM or other MEDIA. Rather than using these cultural forms as sources of ‘data’ about what occurred in places, or as rich evocations of emotional resonance (which had been the tendency in HUMANISTIC GEOGRAPHY; e.g. Pocock, 1981), it unpacked the spatialities of the materials to examine what work they did in representing and shaping cultures. Thus landscape paintings were examined not just for content, but the way in which they framed the landscape – indeed, created ‘landscape’ as a visual category. Often using a linguistic approach, studies treated cultural artefacts as TEXTS that could be read and interpreted to uncover hidden meanings and the imprints of the POWER that shaped them and which they embodied. In this, it drew from the techniques of DECONSTRUCTION and POST-STRUCTURALISM, which focused on how texts shape meaning through processes of exclusion or repression, whereby they downplay or negate some possible interpretations while foregrounding others. The
recovery of these hidden meanings was thus linked to recovering the voices and views of silenced and oppressed groups, especially in studies informed by post-colonialism (Blunt and McEwan, 2002). This latter work also inspired studies of cultural definition and difference (e.g. Anderson, 2007), especially the creation of otherness. Here, the focus became how cultural artefacts were not simply indicators of cultural belonging, waiting to be analysed by academics, but were actively used to signal and create identities by ordinary people.

These two approaches often fused and cross-pollinated. For instance, work on urban ethnicity moved from segregation analyses, of distributions of peoples, to studies of the lived experience of those cultures, how they signified belonging and how they signified exclusion. Rather than now examining the distribution of cultures seen as discrete entities occupying more or less exclusive territories, cultural geography engaged with the study of connections, movements and circulations of meanings in transnationalism and diasporic cultures created in the modern global world. These often form examples of cultural hybridity and hybridization, which confound the exclusions and repressions of hegemonic cultures that sought to maintain a link of people (singular) and territory. Studies saw the multiple categories of identity connected and inflected by people’s local milieu (e.g., on youth, class and race, Nayak, 2003), or looked at the fluidities and fixities of labelling and categorization in transforming urban milieux (Pred, 2000).

Beyond issues of ethnicity, cultural geography moved to explore many other aspects of identity politics (Keith and Pile 1993; Pile and Keith, 1997), such as sexuality and disability, which became ever more salient in the closing years of the twentieth century. The main focus was on practices of inclusion or exclusion, belonging, resistance and identity. A major strand of work emerged around the different forms and modalities of consumption and how this related to people’s identities.

The focus on identity and the meaning of social activities was transplanted into other formerly discrete sub-disciplines. Thus it became increasingly common to see studies of rural cultural geographies, concerning issues of Otherness and identity (e.g. Cloke and Little, 1997), and urban geographies of cultures, political geographies about identity or using similar methods in deconstructing key texts in a critical geopolitics. In economic geography there was a double focus, both on cultural forms in the cultural economy (e.g. Amin and Thrift, 2003) and on ‘enculturing’ approaches – focusing upon processes of meaning and belonging within both firms and markets. In some cases this blurring into other fields has been controversial and has met with hostility from those who regard with suspicion the topical focus (as not being of great importance) or the methods as lacking in either rigour or the appearance of rigour sufficient to persuade policy-makers. There have thus been arguments about the cultural turn going ‘too far’ and undermining former assumptions and unities (Martin and Sunley, 2001). The incorporation of cultural issues has had an energizing effect on other sub-fields, but has also meant that cultural geography’s own distinctiveness has become less clear. As a sub-discipline it has been relatively unconcerned, if not antipathetic, to policing the boundaries of enquiry, especially given how it has shown that definitions enact power relations and often work to exclude groups. Likewise, it has continued to draw catholically from other disciplines, blurring the edges of geography.

Within the sub-discipline, a recent series of debates have begun to challenge some of the certainties that have emerged over the past 20 years. First, while criticisms of idealism have long been levelled at cultural geography, often in the name of re-prioritizing other categories of analysis in the name of historical materialism, a new set of theorizations of materialism have emerged within the sub-field itself. These often refuse the cartesian divide into subject and object, and look at thinking as a material process embedded in the world. They also attempt to provide renewed senses of agency for the material world, rather than just focusing on human agency. Some work challenges the anthropocentric basis of human geography, and culture as a human artefact, drawing on posthumanism and driving renewed studies into animal geographies. Second, debates have contested the focus upon signification and meaning within cultural geography. Instead, recent work flags up the role of habit and routine focusing on the unconscious and preconscious shaping of identities and actions. Third, the focus on the textual mode of interpretation has been argued to privilege representation as a social process. Instead, non-representational theory focuses upon the performance and enactment of identities. This rematerialization and rethinking of cultural geography often
returns to issues of dwelling and the relationship of people, but not peoples, to places drawing inspiration from post-Heideggerian and Deleuzian philosophy. It challenges a preoccupation with representational forms and meaning leading to the social construction of identities. Instead, it focuses upon the connection of material and social process in forging identities in practices and actions. These current debates promise to be as unruly as previous developments, drawing widely from outside the discipline and speaking to topics across sub-disciplines.

**Cultural hearth** The place of origin of a cultural system. This concept was introduced into American CULTURAL GEOGRAPHY by Carl Ortwin Sauer (1952; see also 1969) and was important in the early work of the BERKELEY SCHOOL. Sauer borrowed it from late-nineteenth-century German ANTHROPOGEOGRAPHY, along with the related notions of culture area, CULTURAL LANDSCAPE and cultural diffusion. For many in the Berkeley School, the term was used primarily to refer to the originary point of agricultural systems that had subsequently diffused outwards. For others, it represented the heart of cultural regions more broadly defined (Wagner and Mikesell, 1962).

**Suggested reading**

**Cultural landscape** Conventionally, a principal object of study in CULTURAL GEOGRAPHY. The classic definition is Carl Ortwin Sauer’s (1963b [1925] – see figure):

The cultural landscape is fashioned from a natural landscape by a cultural group. Culture is the agent, the natural area the medium, the cultural landscape is the result. Under the influence of a given culture, itself changing through time, the landscape undergoes development, passing through phases, and probably reaching ultimately the end of its cycle of development.

This definition reflects not only Sauer’s personal context and scholarly concerns (see BERKELEY SCHOOL), but also theoretical issues that remain critical to discussions of cultural landscape. His description of cultural landscape as subject to evolutionary change echoes W.M. Davis’ cycle of natural landscape evolution, but Sauer was explicitly concerned to counter ENVIRONMENTAL DETERMINISM and drew upon German studies of Kulturlandschaft that stressed the mutual shaping of people (Volk) and land in the creation of dwelling (Heimat) (Olwig, 2002). Sauer thus stressed CULTURE as a geographical agent, although the physical environment retained a central significance as the medium with and through which human cultures act (see CULTURE AREA). Hence such elements as TOPOGRAPHY, soils, watercourses, plants and ANIMALS were incorporated into studies of the cultural landscape insofar as they evoked human responses and ADAPTATIONS, or had been altered by human activity.

Today, Sauer’s neat distinction between NATURE and CULTURE has been largely abandoned in favour of a ‘social nature’ (see also PRODUCTION OF NATURE): the tabula rasa of a ‘natural landscape’ upon which ‘culture’ inscribes itself ignores the constancy of environmental change, and the dialectic of ‘nature’ and ‘culture’ is historically constructed. All LANDSCAPES are at once natural and cultural (Cosgrove, 1998 [1984]). Furthermore, contemporaneous CULTURAL ECOLOGY has deepened our understanding of the complexities of cultural landscape change, and POST-COLONIALISM has reworked perspectives on the landscape impacts of COLONIALISM (Sluyter, 2001, 2002; Mitchell, 2002c [1994]). In consequence, greater attention is now given to grids of POWER, to cultural contestation and to the active role played by the diverse ‘insiders’ of landscape, so that Sauer’s idea of a climax cultural landscape swept away by a rejuvenated one has been replaced by notions of a more mediated, HYBRID and transcultural landscape (see also TRANSCULTURATION).

The emphasis on landscape’s representational and semiotic qualities, particularly in studies informed by art history and ICONOGRAPHY, has led to calls for renewed attention to its substantive aspects: its materialities and continued significance for LIFEWORLDS. While cultural landscape remains closely identified with the tangible, visible scene, landscapes are increasingly read by geographers as moments in a networked process of social relations that stretch across TIME and SPACE (see also SENSE OF PLACE). Closely connected to these developments, a nuanced use of PHENOMENOLOGY is apparent in some recent studies of landscape in which narrative...
strategies are used to explore and express the co-constitution of material and experiential space (Wylie, 2002b). Attention to myth, memory and ‘haunting’ embodied in the material landscape is another expression of the retreat from an exclusive focus on representation in cultural landscape studies, but this is also another insistent restatement of the importance of historical apprehension that was the hallmark of Sauer’s original prospectus: but now understood in radically different terms.

cultural politics
The processes through which ‘meanings are negotiated and relations of dominance and subordination are defined and contested’ (Jackson, 1989, p. 2). An insistence that the cultural is political, involving relations of power and conflicting interests between different groups, has been central to much work in cultural studies and, more recently, cultural geography. It depends upon a view of culture as plural, as socially produced and struggled over. Attention has focused in particular on the role of space and place in the construction of meanings and identities as well as processes of resistance and transgression, in recognition that ‘[c]ulture wars are real wars’ (Mitchell, 2000, p. 287).

cultural turn
A set of intellectual developments that led to issues of culture becoming central in human geography since the late 1980s. The renewed interest in questions of culture is not confined to human geography, but within the discipline the cultural turn usually refers a number of related trends:

1. the emergence of a ‘new’ cultural geography;
2. the increasing attention to culture in sub-fields such as economic, environmental, historical and social geographies;
3. claims that culture has become a more important factor in the world itself – for example, in economic processes or in driving political conflict.

Theoretically, the cultural turn has promoted a greater degree of pluralism in human geography, drawing on concepts from other disciplines and focusing attention on multiple dimensions of difference (including gender, race and sexuality). Methodologically, the cultural turn has encouraged the use of a wider range of interpretative and qualitative methods. Epistemologically, the cultural turn has underwritten a commitment to investigating the contingent and constructed qualities of phenomena. It has also gone hand in hand with a ‘geographical turn’ across the humanities and social sciences more generally.

But the cultural turn has also been criticized for distracting geographers from undertaking research that is useful for policy-makers, and for retreating from the ‘materialist’
analysis of power under capitalism. As these objections show, the cultural turn is embedded in wider disputes about the relevance of human geography research and teaching (Barnett, 2004a), but both these criticisms underestimate the ways in which cultural turns have been pursued far beyond the academy and in the very two spheres that the (different) critics identify. Thus cultural economy has demonstrated multiple ways in which ‘fast capitalism’ has taken a cultural turn that involves not only the commodification of culture but also the enrolment of cultural knowledges in economic activities, and still more recently the US military has pursued a ‘cultural turn’ in its search for a new counter-insurgency strategy in its continued military operations in Afghanistan and Iraq (Gregory, 2008b).

In human geography, the concept of culture has had a variable history. In the tradition of American cultural geography associated with Carl Ortwin Sauer, culture was rarely an object of explicit conceptual reflection. This approach concentrated upon the empirical scrutiny of material culture, understood as expressions of unified cultural systems. Such a view was criticized by Duncan (1980) for holding a ‘superorganic’ understanding that reified culture as an independent entity with explanatory force (see Berkeley School). This critique helped inaugurate the development of a so-called new cultural geography, and a broader cultural turn in human geography that drew on concepts of culture from a range of disciplines such as anthropology, semiotics, cultural studies, art history and literary theory. There have been two broad stages in this centring of culture as an object of conceptual debate in human geography. The first stage involved the assertion of the relevance of cultural or broadly interpretative approaches in the discipline. This stage ushered in a number of approaches that emphasized the representational dimensions of cultural processes, and which also tended to be strongly holistic, even functionalist, in their understandings of the relationships between culture and other processes. The second stage of theorizing culture in human geography has concentrated on overcoming the closures inadvertently set in place by the relative success of the first stage.

The new cultural geography that emerged in the 1980s, and the cultural turn that followed in the wake of this and debates around postmodernism, saw the concept of culture subjected to explicit conceptual reflection by geographers. In one strand of research, landscape was re-conceptualized as a ‘way of seeing’, or a ‘text’, or a ‘symbolic form’ or in terms of iconography (see Cosgrove and Daniels, 1988). These moves were often inflected by traditions of Marxism, but specifically by Marxist cultural theory that extended beyond the confines of the Marxist political economy that predominated in human geography (cf. critical theory). This relationship has become increasingly strained, however, as the difficulties of theorizing relationships of agency, determination and meaning from within the Marxist tradition have become more acutely obvious. One outcome of this reconceptualization of landscape has been an anchoring of the concept of culture around a notion of representation understood by analogy with seeing, imagination and vision. This visual account of landscape and culture has
been the occasion for sustained critical thought (Rose, 1993), but this debate about culture and visuality has done little to contest the narrowly visual construal of representation bequeathed by this strand of the new cultural geography (see also vision and visuality).

A second strand of research, emerging from social geography, drew on concepts of culture from the new field of cultural studies. Jackson (2003 [1989]) explicitly drew on Williams’ cultural materialism to outline a programme for a revivified cultural geography. Cultural materialism derives from Williams’s argument that ‘culture is ordinary’, and builds on the notion that culture should be understood as a ‘whole way of life’; that is, an active, lived tradition of meanings or ‘structure of feeling’. Williams drew on diverse sources (e.g. conservative philosopher Edmund Burke and liberal critic F.R. Leavis), but gave them a populist twist. Cultural materialism was intended as a contribution to, but also a move beyond, Marxist understandings of the determinate relationships between economy and culture. Rather than formulating the differing degrees of relative autonomy of levels of a social formation, Williams simply collapsed the base/superstructure distinction of classical Marxism altogether. He did so by extending the notion of ‘materialism’, understood by analogy as any process of active making, to cultural life as well, arguing that culture was the practical activity of producing meanings. This move effectively brackets rather than resolves the key problem referred to by Marxist accounts of materialism, which is not the problem of the ontological status of culture or economy at all, but the problem of theorizing complex causal relations between different practices. Cultural materialism also informs the idea of a ‘circuit of culture’, which has also been influential in human geography. This model integrates different aspects of cultural processes – production and distribution, the ‘text’, consumption and everyday life – into a series of discrete but related ‘moments’ in an ongoing circulation of meaning-making (du Gay, Hall, Janes, McKay and Negus, 1997). Theoretically, the ‘circuit of culture’ privileges meaning as the essential quality of cultural processes. Methodologically, it provides a practical means of undertaking empirical work on specific cultural practices while remaining true to the axiom of cultural practices that need to be understood in relation to the totality of other practices of which they are a part.

These two strands of thought on culture (in terms of visual representation and in terms of meaning-making) have served as an important route towards a widespread engagement with post-structuralism in human geography, with its emphasis on exposing the contingency of supposedly natural forms through the deployment of interpretive methodologies. Culture has been consistently construed in representational terms by geographers (and according to an impoverished understanding of representation at that); or in terms of the intangible or ideational aspects of processes that are somehow realized or materialized in some concrete form. This first stage of theorizing culture in geography has therefore been supplanted by a second, more critical stage in which the limitations of these concepts of culture have been challenged. One feature of this second stage has been the ascendancy of an ontological register of theory, involving the abstract delimitation of the ‘the cultural’ from ‘the economic’, ‘the representational’ from ‘materiality’, or ‘the human’ from ‘the non-human’, followed by the assertion of their inevitable entanglement.

The starkest example of this ontologization of theory is Mitchell’s (2000) argument that ‘there is no such thing as culture’. This claim selectively invokes an essentialist criterion of definition to assess the validity of the concept of culture, which – it is supposed – must refer to an ontologically independent thing-like entity in order to have any salience. On these grounds, Mitchell concluded that ‘“culture” has no ontological basis’ (ibid., 12), and that culture ‘represents no identifiable process’ (ibid., 74). Mitchell also argues that the concept of culture is used as an explanatory category in both cultural studies and in human geography. This claim wilfully overlooks the processual, action-oriented and practice-focused conceptualizations of culture in both fields. In place of these, Mitchell recommends an explicitly reductionist model of culture understood as merely a medium for symbolizing more fundamental economic, political and social processes. There is really just ‘a very powerful ideology of culture’ (ibid., 12), developed and deployed to control, order and define ‘others’ in the name of power and profit’ (ibid., 75). Despite its ostensibly Marxist credentials, this approach to culture negates a long-tradition of Western Marxism, one in which ideology and culture are explicitly defined against this sort of explanatory reductionism (see also critical theory). The idea that culture is merely a medium through which the prevailing order of things is naturalized (i.e. a mode of reification) is
a throwback to the nineteenth century, and does not stand up after the reorientation of questions of culture and ideology away from ‘consciousness’ towards ‘SUBJECTIVITY’ that the twentieth-century tradition of Western Marxism did much to inaugurate.

Mitchell’s materialist correction of what he claims are politically quiescent concepts of culture is just one example of the vocabulary of ‘materiality’ coming to the fore in recent theorizations of culture in human geography. Calls for the ‘rematerializing’ of cultural geography (Jackson, 2000) now abound. This usually means looking more closely at material cultures of artefacts and objects; at issues of embodiment; and at the entanglement of ‘the cultural’ and ‘the economic’. The ascendancy of this ontological register goes along with attempts to supersede the narrow understandings of representation, vision, meaning and textuality that geographers constructed through their initial engagements with post-structuralism. But the ‘materialist’ turn compounds the limitations of that construal, reinstalling dualisms between ideal and material, subject and object, and the representational and the non-representational. Calls for the rematerialization of culture, or indeed of human geography in general, give the impression that the value of a concept lies in its ability to disclose some level of ontological existence. But culture is not really an ontological category at all; it is a functional category of attribution, in the sense that to call something cultural is to ascribe a particular set of purposes and qualities to it, not to attribute a finite set of characteristics that define its essence.

The challenge to concepts of culture in human geography is not a matter of getting the correct ontology. It lies, rather, in loosening the hold exerted by holistic conceptions of culture that allow various sorts of exorbitant claims of political relevance to be ascribed to cultural analysis. Culture is often ascribed a particular sense (as one aspect of meaning of human affairs), and a very general and even totalizing (in which it is assumed that whole ways of life are unified and integrated through norms, meanings and values). The idea of ‘CULTURAL POLITICS’ often rests on claims that social totalities are in some way integrated, refracted or mediated through culture. There is a paradox here: holistic concepts of culture as meaning and symbolization help to acknowledge the political salience of cultural processes, but only at the cost of invoking undifferentiated concepts of POWER. By conflating politics with culture, this leads to the failure to think about the consequences of what it might mean if politics needs to be supplemented (cf. DECONSTRUCTION) by cultural processes of symbolization, representation or mediation in the first place. What is left aside as a result is the question of what sorts of powers are intrinsic to cultural processes themselves – powers such as authority, charisma, desire, feeling or seduction.

Three overlapping trends are likely to inflect the conceptualization of culture in human geography in the near future. In each case, it is by returning to a sense of culture as practice that progress is likely to be made. First, there is interest in concepts of culture that draw on Foucault’s ideas of GOVERNMENTALITY. In this approach, culture is defined as a set of aesthetic practices for cultivating the capacities for self-regulation (Bennett, 1998). This approach explicitly builds upon a genealogical analysis of the accretion of meanings of ‘culture’ as an independent and autonomous field. It reads this as an index of the practical deployment of culture as a medium for ‘acting on the social’. This line of thought is open to an instrumentalist interpretation in which culture is understood as a medium for legitimizing or resisting the power of the STATE or CAPITAL (see INSTRUMENTALISM). But its real potential lies in disclosing some of the powers that are specific to cultural processes. One feature of the modern concept of culture that this approach focuses upon is the antithetical and self-divided structure of modern definitions of the term: not only is culture defined against SOCIETY, anarchy or NATURE; but it is also internally divided against itself, into high and low, elite and popular or mass. This ‘splitting of culture’ (Bennett, 1998, p. 82) is crucial to understanding the powers of culture: it defines a range of resources that can be deployed to transform conduct and behaviour (e.g. a canon of great works, or various repertoires of cultural judgement); and it also defines a range of domains that can be transformed through the application of these resources (e.g. ‘cultures of poverty’, ‘institutional cultures’, ‘the culture of schooling’). This analysis of culture as both a medium and object of transformation owes a great deal to a tradition of anti-colonial and post-colonial cultural theory (see POST-COLONIALISM: see also Said, 1993). However, the strong Foucauldian inflection of the concept of culture implies a less holistic imagination of the relationship between culture and power than is implied by concepts such as cultural IMPERIALISM, HEGEMONY and ideology (Barnett, 2001).
A second area in which the powers of culture are foregrounded follows from and develops Stuart Hall’s seminal analysis of the concept of *articulation*. Grossberg (1993, p. 4) develops an explicitly ‘spatial materialism’ that also builds on Deleuzian thought to argue that the concept of culture needs to be changed from that of ‘the field in which power is symbolized to a set of practices which apply power’. This is related to a shift from the interpretative apprehension of meanings to a consideration of the production of relations, and recasts cultural studies as ‘a theory of contexts’. There is considerable potential here for geographical research, as there is in the closely related reorientation of cultural analysis away from narrowly construed issues of meaning towards embodied practices of feeling, shame and compassion (e.g. Berlant, 2004). The third area of growing interest lies in moves to rethink culture as a field of performance and action (e.g. Hastrup, 2004). Here, again, there is a move away from holistic accounts of how culture symbolizes and integrates other social relations, towards an emphasis on the specific powers of cultural practices, and suggesting new models of relations and agency in the process (Strathern, 1995).

The odyssey of the concept of culture in human geography is likely to continue awhile yet, but do not expect anyone to arrive at a singular, ontologically robust definition. Duncan and Duncan (2004a) recommend the self-consciously eclectic combination of theories of culture backed up by empirical analysis, and this seems more in the spirit of the traditions of cultural studies and anthropology from which human geographers have drawn so much inspiration. Flexibility is one of the reasons why ‘culture’ can serve as a useful *lingua franca* between otherwise disparate and disconnected fields. But the continuing influence of cultural analysis in the discipline depends on the acknowledgement that there is more to culture than meaning and representation; and more to culture than the reproduction of or resistance to power relations constituted by more fundamental processes. Above all, it requires a greater degree of concern with what cultural studies can teach us about how to do theory itself – that theory is not about arriving at essentialist criteria or the vain search for ontological clarity, but is about appreciating the *essentially contested* qualities of concepts, and analysing what is most at stake in these disagreements.

Frow (1997); Johnson, Chambers, Raguram and Tincknell (2004); Mulhern (2000); Robbins (1993); Williams (1981); Yudice (2003).

**culture area** A geographical region over which homogeneity in measurable cultural traits may be identified. Contiguous zones identified within a culture area are *core*, over which the culture in question has exclusive or quasi-exclusive influence, *domain*, over which the identifying traits are dominant but not exclusive, and *realm*, over which the traits are visible but subordinate to those of other culture groups. The classic study is Meine’s (1965) identification of a Mormon culture area centred on the Great Basin of Utah. Today, the concept is little used in GEOGRAPHY, as culture is identified more closely with PROCESS, connection and NETWORK than with the areal boundedness of mappable cultural markers.

**cybernetics** Derived from the Greek ‘*cybernetes*’, meaning ‘steersman’, it sees systems as learning and self-regulating. The term ‘cybernetics’ was first used by the INFORMATION THEORY pioneer Norbert Wiener in his 1948 book *Cybernetics: or control and communication in the animal and the machine*. The term has often impacted on geography through compound forms such as ‘cybernetic organism’, abbreviated to CYBORG, and ‘cybernetic space’, abbreviated to CYBERSPACE. However, two specific inflections of the term in GEOGRAPHY are worth noting in themselves.

First, the term has literal and metaphorical resonance with work that has used MODELS and algorithmic programming to simulate geographical phenomena. The weaker version of this is an EPISTEMOLOGICAL inclusion of FEEDBACK in models. ALGORITHMS as series of calculations or procedures can be sequences where each step depends upon the previous ones. Sophisticated AGENT-BASED MODELLING thus has co-dependent multiple calculations. The stronger version is an ONTOLOGICAL statement that sees the world as operating as, or analogous to, a NEURAL NETWORK. Thus the world can be seen as operating like information passing through a system. Cybernetics focuses upon the relationships of these parts to see how the whole system is controlled or governed. This has the virtue of moving away from a CARTESIAN division of thought and the world, by insisting on seeing the world as a thinking, REFLEXIVE entity. However, it also risks reducing thought to a communication system and providing a mechanistic view of the world.
Second, cybernetic space has been used in distinction to the abridged CYBERSPACE to emphasize the way in which electronic communication and information processing capacities interact with the real world (Mitra and Schwarz, 2001). Far from creating a separate virtual realm, information processing capacities are regularly embedded in everyday devices so that they are able to respond and either be programmed or learn about patterns of use – offering the prospect of a world of ‘ubiquitous computing’ (sometimes abbreviated to ‘ubicomp’). Increasingly, life in the urbanized WEST depends on these embedded processors, which regulate temperatures, elevators, traffic and an array of taken-for-granted processes. With the variety of wireless technologies, devices can communicate with each other without the user necessarily being aware that an automated electronic conversation is occurring. They use ‘soft’ adaptive computational processing that creates ‘a technical substrate of unconscious meaning and activity’ embedded in the environment (Thrift and French, 2002, pp. 312, 322). These devices would create ‘smart’ environments or ‘ambient intelligence’ that can keep track of users and will tailor interactions to suit the users. Thus they will communicate and remember past purchases, preferences, previous visits and past actions. This, the designers believe, will be used to provide customized menus or facilities. Cybernetics points out that this builds adaptive, reflexive capacity into the very environment, rather than vesting it solely in human agents.

cyberspace A term that has followed a rapid arc from subcultural obscurity to media ubiquity, and is now often seen as academically misleading. It was famously coined in the novel Neuromancer by William Gibson, first published in 1984 (see Gibson, 1986). In his novel, he offered a futuristic vision:

Cyberspace. A consensual hallucination experienced daily by billions of legitimate operators, in every nation, by children being taught mathematical concepts . . . A graphic representation of data abstracted from banks of every computer in the human system. Unthinkable complexity. Lines of light ranged in the nonspace of the mind, clusters and constellations of data. Like city lights, receding into the distance . . .

Gibson was writing (on a Remington typewriter, before the first widely available Graphical User Interfaces even appeared on desktop computers) about the emergence of a networked and immersive environment. Gibson’s vision is replete with spatial METAPHORS and imaginaries for interactive fora created out of data and information. In other novels, he models online worlds on the walled city of Kowloon (Idoru) or a variety of urban dystopias.

The use of cyberspace in this phase was connected to dystopian cyberpunk science fiction that broke from conventions of seeing technology as promising an ever-brighter and cleaner MODERNITY (Burrows, 1997; Featherstone and Burrows, 1997; Kitchin and Kneale, 2002), to one that saw it as connected to or enabling social and personal fragmentation, woven amidst LANDSCAPES striated by effects of POWER and INNOVATION, but also decay and dispossession.

This gave impetus to seeing flows and exchanges of data and information not merely through SPACE but as creating online worlds where data were manipulated as virtual artefacts (see also VIRTUAL REALITY). The representations and MAPS of cyberspace created by programmers and writers did indeed precede the TERRITORY in Baudrillard’s sense (see also SIMULACRA) – they were vital in its creation, in giving information specific forms and idioms for use. The mapping of cyberspace spawned new technologies to locate and understand data, and set up an intriguing dialogue with cartographic concepts now applied to imagined objects (see Crampton, 2003; Dodge and Kitchin, 2001a).

From this beginning, cyberspace entered wider academic and popular parlance, along with a string of other spatial metaphors for information NETWORKS. Thus the 1990s saw the rise of discourses imagining what Kitchin (1998) called the ‘world in the wires’ through spatial metaphors such as ‘chat rooms’, informational highways, ‘electronic frontiers’ and ‘cybersalons’ (see VIRTUAL GEOGRAPHIES). Indeed, new virtual worlds were designed where ‘avatars’ or online representations of users could interact in virtual realms (see, e.g., Anders, 1998). The possibilities for new realms of interaction attracted a great deal of attention in the mid-1990s. The possibilities of playing with IDENTITIES such as GENDER ascriptions were pursued alongside questions of the formation of online COMMUNITIES without spatial proximity in the real world. Far from the cyberpunk chaos of early accounts, many online worlds developed in the new millennia became mainstream, and quite
suburban and conventional (with popular online environments such as Second Life having more than seven and half million users in 2007, and a slogan ‘Your world. Your imagination’ suggesting that most users had fairly conventional imaginations), while others retained a focus on gaming. Meanwhile, online sources of information have become as usual and familiar as traditional MEDIA – with online versions of conventional media and alternative media rescaling audiences, while the ‘blogosphere’ provides alternative fora (see, e.g., Chang, 2005). Other new media are woven into our everyday lives as part and parcel of our normal, material lives (see, e.g., Morley, 2003; Yoon, 2003):

The 1990s were about the virtual. We were fascinated by the new virtual spaces made possible by computer technologies. Images of an escape into a virtual space that leaves physical space useless, and of cyberspace – a virtual world that exists in parallel to our world – dominated the decade. . . . By the end of the decade, the daily dose of cyber-space (using the internet to make plane reservations, check email using a Hotmail account, or download MP3 files) became so much the norm that the original wonder of cyberspace – so present in the early cyberpunk fiction of the 1980s and still evident in the original manifestos of VRML evangelists of the early 1990s – was almost completely lost. The virtual became domesticated. (Manovich, 2006, p. 220)

By the millennium, even as these online worlds expanded their users, the notion of an immaterial or ethereal set of worlds as a MODEL for informational landscapes seemed to miss many dynamics. Most especially, it missed the increasing mixture of the virtual into both EVERYDAY LIFE and also everyday spaces. Far from entering a world online, the informational world began to permeate our lived environment. Increasingly, processing power was located in the environment around us, not just in discrete artefacts called computers. As mobile telephones, ‘smart’ devices and electronic sensors led automated responses, the separation of an online and offline world seemed anachronistic.

cyborg The shackling together of ‘cybernetic’ and ‘organism’ in the term ‘cyborg’ is designed to convey the combination of ANIMAL (usually humans) and technology. Initially drawn from science fiction, it has been taken on to critique technological futures based on a CARTESIAN division of mind and BODY. It was popularized and developed by Donna Haraway (1991a) to criticize what she called a MASCULINIST fantasy of second birthing in technological UTOPIAN writing. This technological fantasy suggested an ideal of a transcendent union of human and machine, with people uploading their consciousness into machines. The aim would be eternal life in a disembodied state in the realm of CYBERSPACE. In cyberpunk writing, this was often depicted as fusion of hardware and software escaping the limits of the ‘meatware’ (aka the human body).

This imaginary builds on deep-seated divides of mind and body. Cartesian PHILOSOPHY had powerfully divided thought and world (res cogitans and res extensa, respectively). This compounded medieval Christian tradition, which had developed the model of the Manichean divide of the spirit and the flesh, the former being divine and the latter earthly, sins being located with the body and virtue with the mind. Feminist critics (see FEMINISM) have long pointed out that these divisions become gendered to associate women with the body and the material, while men were associated with logic and thought. The technological fantasies of escaping the body simply restaged these debates.

The concept of the cyborg linked flesh and body to emphasize the materiality of lives and technological transformations, and to show that humans are always part of the world and entangled in technologies. The perspective links with POSTHUMANISM in challenging an autonomous and FOUNDATIONAL humanity. It implies that human intelligence and consciousness shape, but also are shaped by, technologies. While ‘such FEEDBACK loops may be reaching new levels of intensity as our environments become smarter and more information rich, . . . the basic dynamic is as old as humans’ (Hayles, 2002, p. 303).

The term is also used to point to accelerating vectors of technological development in technoscience and BIOTECHNOLOGY that are directly fusing technical implants with animals, often to restore lost capacities. In benign ways, this is seen as augmenting the capacities of bodies. Rather than transcending the body, it is about prostheses that expand our reach or capacities. More critical accounts point out that work on ‘human augmentation’ has been most enthusiastically
supported by the military–industrial complex, in efforts to create advanced soldiers (Gray, 1995, 2003). The figure of the cyborg is thus often used to highlight the powerful myths of technology and humanity, and the investments in them by medical and military discourse.

cycle of poverty  The idea that poverty and deprivation are transmitted from one generation to the next. The work of Oscar Lewis in the 1960s (see Lewis, 1969b) presented the victims of poverty as the authors of their own misfortune. Members of poor families were said to place little value on education, hard work or sexual responsibility. The empirical evidence for this behavioural view of poverty is slight, although it feeds into talk of an underclass. Other poverty cycle models pay more attention to neighbourhood effects (bad schools, lack of jobs, danger), or the determining effects of social divisions structured around class, gender and race.

Darwinism  Narrowly construed, Darwinism refers to the theory of evolution developed by Charles Darwin (1809–82) and initially published in *The origin of species* (1859). The term itself was coined by Thomas Henry Huxley in his 1860 review of *The origin* to identify the central component of the theory; namely, the mechanism of natural selection, according to which organisms born with any advantageous feature have selective advantage over rivals in the struggle for life. Yet Darwinism, more broadly understood, conveys numerous associated ideas including common organic descent, gradualism and the multiplication of species, and such additional mechanisms of evolutionary transformation as sexual selection, group selection and correlative variation (Bowler, 1989).

At the same time, Darwinism is also associated with at least two further suites of ideas – social Darwinism and neo-Darwinism. *Social Darwinism* is usually taken to refer to the application of Darwinian principles and mechanisms to human society, and often is thought to have justified anti-interventionist, *laissez-faire* economic policies on the basis of a ‘survival of the fittest’ ideology. Trading on organic analogies, the idea is that human societies and institutions are subject to the laws of evolution by selection and struggle, and that human intrusion constitutes unwarranted interference in the processes of natural development. Such perceptions need modifying in at least two respects. First, there are good grounds for supposing that social thinking, notably in the form of Malthusian demography (see *Malthusian model*), was integral to Darwin’s theory from the beginning and it is thus not simply a case of extending its application from the natural to the social world (Young, 1969). Darwinism, in this reading, always was social (Greene, 1977). Second, revisionist social evolutionists could equally mobilize the theory, sometimes drawing on its Lamarckian counterpart, to justify interventionism and political reform (Jones, 1980). *Neo-Darwinism* (or the neo-Darwinian synthesis as it is usually known), refers to the classical theory of evolution that emerged during the 1930s when R.A. Fisher, J.B.S. Haldane and Sewall Wright – building on T.H. Morgan’s earlier chromosomal theory of inheritance – combined Darwinian natural selection with a quantitative approach to population genetics that served to show the compatibility between Mendelian genetics and Darwin’s mechanism (Smocovitis, 1996). This synthesis rescued Darwinism from the attacks to which it had been subject in the decades around 1900 from figures such as William Bateson and Hugo DeVries, who had argued that evolution took place by saltation; that is, by discontinuous variation (Bowler, 1983).

Within geography, Darwinian thinking in its various guises – sometimes in association with LAMARCK(IAN)ISM – has exerted considerable influence. Stoddart (1966) identified ideas of change through time, organization and ECOLOGY, selection and struggle, randomness and chance, as key Darwinian influences on geography, though some of these were already established in the tradition prior to Darwin’s intervention and were, in any case, compatible with Lamarckism. Whatever the precise genealogy, evolutionary thinking in one form or another found expression in almost every sub-disciplinary specialism of geography. W.M. Davis’ cycle of erosion gave an evolutionary reading of LANDSCAPE development – though hardly in any specifically Darwinian sense, given the absence of sexual reproduction and inheritance as the drivers of change, as Darwin envisaged it (see also PHYSICAL GEOGRAPHY). Frederick Clements’ plant geography displayed his fascination with organic modes of thought, and the Russian geographer and ichthyologist Lev Semyonovich Berg developed a Darwinian theory of ‘nomogenesis’ that, by emphasizing mutations, allowed for evolutionary ‘jumps’ (see also BIOGEOGRAPHY). Friedrich Ratzel’s ANTHROPOGEOGRAPHY disclosed an organismic conception of the STATE and translated into HUMAN GEOGRAPHY Moritz Wagner’s Lamarckian-inspired MIGRATION theory. Derwent Whittlesey’s scheme of SEQUENT OCCUPANCE and H.J. Fleure’s geographical anthropology and anthropometric CARTOGRAPHY were also evidently imbued with evolutionary thinking. In the latter case, the interplay of racial type, evolutionary mechanisms, anthropometric localization and psycho-social factors were of central importance.
Besides these individuals, a variety of key issues within the geographical tradition drew heavily on evolutionary motifs. Statements of ENVIRONMENTAL DETERMINISM by figures such as Ellen Semple, Elsworth Huntington and Griffith Taylor were invariably couched in evolutionary categories, with CLIMATE, migration and natural selection routinely playing the leading roles. From a more radical perspective, Peter Kropotkin found in a modified Darwinism the grounds for championing collectivism, opposing Spencerian individualism and connecting up the philosophy of natural science with ANARCHISM. This essentially Russian reading of evolution drew inspiration from the St Petersburg naturalists, all of whom had conducted FIELDWORK in Siberia, in conditions markedly different from the tightly packed-in niches of the tropical world – in particular, from the work of Karl Kessler, who set out the law of mutual aid. The transference of ideas about community between sociology and ECOLOGY, couched within an evolutionary POLITICAL ECONOMY, also found expression in geography in the tradition of HUMAN ECOLOGY (Mitman, 1992). Debates about acclimatization were likewise connected up to questions about heredity and ADAPTATION (Livingstone, 1987a; Anderson, 1992). And early theoretical statements about REGIONAL GEOGRAPHY, such as those of Herbertson and Geddes, were supported by appeals to the need for elucidating evolutionary mechanisms in specific contexts (Livingstone, 1992).

Within contemporary human geography, issues raised by Darwinism continue to surface. The legitimacy of transferring biological categories to the social order, for example, continues to be the subject of debate (cf. BIO-POWER), as are matters rotating around the understanding of how NATURE and CULTURE – to employ two abstractions – are to be conceptualized. Recently too, enquiries have been undertaken into the geography of Darwinism, with the aim of ascertaining the ways in which evolutionary theory circulated around the world and was differently embraced, mobilized and resisted in the light of local CULTURAL POLITICS (Livingstone, 2006).

data archive A central repository of accessible data sets. Researchers are encouraged to deposit original data sets (e.g. survey data) there to enable others to conduct SECONDARY DATA ANALYSES. Many countries now have such archives (usually sponsored by research funding agencies that encourage – in some cases require – researchers to deposit data sets to encourage social scientific advances through the re-analysis of existing data sets alongside the creation of new sources). These archives are increasingly used to store and disseminate not only original data sets collected by academic researchers but also those collected by public-sector bodies (such as CENSUSES). Although most of those archives focus on quantitative data, other types are now stored in formats that allow them to be made readily available to other researchers – as in Qualidata, part of the UK Data Archive housed at the University of Essex (see SOFTWARE FOR QUALITATIVE RESEARCH) – and archives that store maps in digital form, and the INTERNET has facilitated linking archives to enable international data-sharing. As well as storing data, most archives offer training and other forms of user support to facilitate analyses of the data sets held.

data mining Computer-based automated procedures for searching large and complex data sets in order to identify spatial patterns and relationships, either to confirm existing or to generate new HYPOTHESES. In SPATIAL ANALYSIS, Openshaw’s GEOGRAPHICAL ANALYSIS MACHINE and GEOGRAPHICAL EXPLANATION MACHINE exemplify data mining algorithms, as do some aspects of GEODEMOGRAPHICS. Some term these practices ‘data dredging’, since they are based on little prior knowledge and exemplify inductive thinking (see INDUCTION) whereby explanations are sought after patterns are identified (cf. EXPLORATORY DATA ANALYSIS); however, they can also be abductive (cf. ABDUCTION; GEOCOMPUTATION). Many of the structured algorithms for data mining use ARTIFICIAL INTELLIGENCE approaches.

decentralization A process of spatial change generated by centrifugal forces (cf. CENTRIFUGAL AND CENTRIPETAL FORCES). Within urban areas (see URBANIZATION), demands for space
DECISION-MAKING

and to avoid the congestion, pollution and land costs of high-density areas stimulate decentralization into suburbs and beyond, whereas at larger scales the negative externalities of large cities encourage movement to smaller settlements (cf. COUNTER-URBANIZATION). Decentralization is facilitated by reliance on roads for the movement of goods and individuals.

Decision-making: The process whereby alternative courses of action are evaluated and a decision taken. The decision-making perspective attracted great interest after it was introduced to geography during the 1960s as part of the behavioural movement (see BEHAVIOURAL GEOGRAPHY). It broadened traditional perspectives, making them more realistic with respect to human practice.

The crux of the decision-making perspective is the recognition that real-world location decisions are seldom if ever optimal in the sense of maximizing profits or minimizing resources used. Similarly, consumer behaviour hardly ever accords with the rational calculus of utilities assumed in conventional economic formulations. The all-knowing and perfectly able economic actor of neo-classical economics bears only slight resemblance to actual human beings.

Sub-optimal location decision-making may be incorporated into conventional location theory by the use of spatial margins to profitability within which some profit is possible anywhere and the business is free to locate away from the optimal (profit-maximizing) location at some pecuniary cost. However, this tells us nothing about how actual choice of location is arrived at within the economically determined constraints.

A step further was taken by Allen Pred (1967, 1969) in his concept of the behavioural matrix. According to this, decision-makers have a position in a matrix with the information available on one axis and the ability to use it on the other. The more information and the greater the ability, the higher is the probability of a 'good' location within the spatial margin; that is, near the optimal location on cost/revenue grounds. Decision-makers with very limited ability and information are more likely to locate beyond the margins and fail, but a good location could still be chosen by chance.

Pred was greatly influenced by H.A. Simon's (1957) concept of satisficing behaviour, as an alternative to the unrealistic optimizing capacity attributed to 'economic man' (sic). Decision-makers were viewed by Simon as considering only a limited number of alternatives, choosing one that is broadly satisfactory rather than optimal. The introduction of a more realistic perspective on location decision-making corresponded with a similar move in the study of business behaviour in general, within a broad context of industrial organization.

The decision-making perspective in locational analysis followed two routes: theoretical and empirical. The search for a theoretical framework for studies of location behaviour under conditions of risk and uncertainty led geographers and regional scientists into such fields as game theory and organization theory, and more recently to use large-scale simulation models, as in agent-based modelling (cf. artificial intelligence). The light shed on actual decision-making was very limited, however.

An empirical approach promised more, in a field where the emphasis is so much on individual practice. There was a tradition of survey analysis in industrial location studies well before the behavioural movements penetrated the subject. Such research often revealed the importance of 'purely personal' factors. Later empirical research preferred to take sets of firms and examine the actual process of decision-making. Some perceived problem (such as undercapacity) sets in motion a sequence of decisions beginning with whether to expand in situ, to set up a branch or to acquire an existing plant; the sequence continues with the process of searching for a site, the evaluation of alternatives, the final decision and the feedback of the learning experience into some subsequent decision of a similar nature. This empirical approach held out the prospect of generalizations that relate the process of location decision-making to the nature of the organization concerned (cf. search behaviour).

After many years of behavioural studies of industrial location decision-making, the findings seemed to promise more than it was able to deliver. A critique was mounted by Doreen Massey (1979), who pointed to objections on epistemological grounds (see EPISTEMOLOGY) to the practice of adopting ideal type constructs (whether 'economic man' or some 'satisficing man') and of making a distinction between behaviour that accords with the ideal type and that which must be attributed to other factors. Massey argued that the focus on individual decision-making distracts attention from the structural features of the economy to which firms react, and that what
firms actually do with respect to the setting up or closure of plants is best understood in this broader context of political economy. There has recently been a revival of interest in aspects of location decision-making, however, including the learning process and corporate strategy with respect to restructuring. The work of Schoenberger (1997) emphasizes recognition of the significance of cultural factors to the operation of the firm.

Other aspects of human geography in which the decision-making perspective assumed importance include response to environmental hazards (e.g. Kates, 1962), residential choice (e.g. Brown and Moore, 1970), shopping behaviour (e.g. Rushton, 1969: see also revealed preference analysis) and the decision to migrate (e.g. Wolpert 1965). Again, neo-classical economics was originally influential, the concept of place utility being an obvious geographical extension of the theory of consumer behaviour. While qualities of place as people evaluate them do influence decisions including locational choice or movement, there are many other considerations of a fortuitous and seemingly irrational nature. Indeed, geographers can easily exaggerate the spatial element in decision-making.

Research involving qualitative methods has sought a more sensitive understanding of how people assign meaning to various aspects of life and how decisions follow from this. For example, the decision to seek health care, involving the coverage of distance, is influenced by culturally specific conceptions of the meaning of illness, personal and shared experience of being ill, assessment of the benefit likely to be derived from the doctor’s advice based on past contacts, the felt need for treatment or reassurance, and so on. Such work helps to set the spatial aspects of decision-making and taking in a broader context, getting away from crude notions of human behaviour as some stimulus–response mechanism and allowing greater scope for the way meaning is interpreted and translated into action. Work in the earlier tradition is now part of the discipline’s history rather than important to contemporary practice. DMS

decolonization The process, often long, tortuous and violent, by which colonies achieve their national aspirations for political independence from the colonial metropolitan power (cf. nationalism). Decolonization can be understood as the period of later colonialism (Chamberlain, 1985). Modern colonialism covers the period from the fifteenth to the twentieth centuries, and hence decolonization is uneven in its geography and history. In the New World, which had been subjected to Spanish, French, Portuguese and Dutch colonial rule in the First Age of Colonialism, the first wave of decolonization occurred in the eighteenth century. In this regard, the so-called Classical Age of Imperialism in the last quarter of the nineteenth century was short, the first decolonizations of the second wave being achieved after the end of the Second World War. The two cycles of imperialism both concluded with a limited phase of decolonization, followed by the rapid collapse of empires and an irresistible push to political independence (Taylor, 1994b).

The first challenge to the first wave of imperialism came in 1776, as British North American colonies declared independence. While Britain maintained its Caribbean and Canadian colonies, the Napoleonic upheavals in Europe so weakened Spain and Portugal that European settlers from Mexico to Chile expelled their imperial masters. By 1825, the Spanish and Portuguese empires were dead (cf. Latin America). In the subsequent 115 years up to the Second World War, decolonization was limited to Cuba in 1898 and two groups of British colonies: the white settler colonies (Canada, Australia, New Zealand and South Africa) granted internal autonomy and finally full sovereignty in 1931, and Egypt and Iraq after the First World War. The Second World War marked the death knell for European colonization: India’s separation from the British, Indonesia from the Dutch, and the remaining Arab mandated territories and Indo-China from the French. The independence of Ghana in 1957 marked an avalanche of liberations in Africa, though the process was not complete until 1990 (Namibia). Between 1945 and 1989, over one hundred new independent states were created.

Decolonization is a process marked by the achievement of political independence, but the duration, depth and character of decolonization movements vary substantially. In some African colonies, colonization was barely accomplished, and resistance movements of varying degrees of organization and institutionalization attended the entire colonial project. In other cases, an organized anti-colonial and nationalist movement came late, accompanied
by a rapid and hastily assembled set of political negotiations in which it is clear that the metropolitan power wished to hand over the reins of power with utmost expediency (Nigeria). In others, it took a war of liberation, a bloody armed struggle by leftist guerrillas or nationalist agitators pitted against white settlers or intransigent colonial states (as in Laos, Vietnam and Zimbabwe).

One of the problems with analysing decolonization, as Fred Cooper notes (1997, p. 6), is that the story ‘lends itself to be read backwards and to privilege the process of ending colonial rule over anything else that was happening in those years’. It should also be said that any account of decolonization presumes an account, or a theory, of colonialism itself: top-down interpretations take colonial projects at face value, whereas the nationalist account denies any reality to the goal of modernization that the colonial state purported to bring. In general, decolonization is seen as either (i) self-government as an outcome of negotiated preparation and vision from above by a colonial state apparatus, or (ii) as a nationalist triumph from below, in which power is wrested (violently or otherwise) from recalcitrant colonizers. In practice, decolonization was an enormously complex process involving something of each, and shaped both by the peculiarities of colonialism itself and the particular setting in world time in which the nationalist drive began.

There are two forms of decolonization that rest on what one might call nationalist triumph. The first is built upon social mobilization in which a patchwork of anti-colonial resistances and movements (many of which are synonymous with colonial conquest itself) are sown together into a unified nationalist movement by a Western-educated elite (Malaysia, Ghana or Aden). Mobilization occurred across a wide and eclectic range of organizations – trades unions, professional groups, ethnic associations – bringing them into political parties and propelled by a leadership focused on racism, on liberation and the sense of national identity of the colony, given its own history and culture. The second is revolutionary – Franz Fanon (1967 [1952]) is its most powerful and articulate spokesman – in which the vanguard is not Western-educated elites or indeed workers, by the peasants and lumpenproletariat. It rested upon violence and rejection of any semblance of neo-colonialism. Decolonization rejected bourgeois nationalism (of the first sort); rather, as Fanon put it, ‘the last shall be first and the first last. Decolonization is the putting into practice of this sentence’ (1967, p. 30).

Both views depict nationalism as subsuming all other struggles and hence obscures and misses much history; both posit a True Cause, as Cooper (1997, p. 7) puts it, in which there is little truck with opposition. Mamdani’s (1996) enormously influential book on Africa makes the important point that decolonization posed the possibility of breaking with the traditional of European colonial indirect rule (what he called ‘decentralized despotism’) in which African custom granted enormous powers to local systems of traditional (and therefore cultural) authority, and developing instead a sort of civic nationalism in which cultural politics did not play a key role. Most African states continued the colonial model in which African colonial subjects were granted racial equality and citizenship rights, but in which ‘indigenes’ were simultaneously a sort of bonus. In the historiography of the period, the nationalist road to self-government tends to take for granted the depth and appeal of a national identity (cf. identity politics). It is precisely the shallowness of these nationalisms in the post-colonial period that reveals how limited is the simple nationalist account of decolonization itself. In practice, decolonization occurred in the context of all manner of contradictions and tensions between the national question and other social questions.

There is also a narrative of decolonization that has a singular vision, but from the side of the colonial state. It was the colonial bureaucracy, long before nationalist parties arose, that shaped self-government on a calculus of interest and power derived from an older conception of colonial rule (New Zealand and Canada) as a stepping stone to independence. In this view, Africa by 1947 had already been set on the road to decolonization – this is a classic instant of Whig history – in spite of the fact that the Colonial Offices typically saw early African leaders as schoolboys or demagogues (Cooper, 1997). Another version of the dirigiste theory is rendered through the cold calculation of money and cost. It was the decision-making rationale of accountants estimating costs and gains – and who in particular gained – against the backdrop of imperial power’s economic performance after the Second World War that sealed the fate of the colonies.

In all of these accounts – for India as much as Indonesia or Iraq – colonialism is as monolithic as the explanations themselves. There is a reduction involved in seeing Indians or
Kenyan colonial subjects or as national or proto-nationalist actors. An alternative approach pursued by the so-called Subaltern School (Guha and Spivak, 1988; see SUBALTERN STUDIES) sees colonialism as a contra metropolitan project, moving against trends to exercise power under universal social practices and norms. It was ‘dominance without HEGEMONY’. In other words, the hegemonic project of colonialism fragmented as colonial rule attached itself to local idioms of power. From this experience characterized by hybrid forms of identity, blurred boundaries and contradictory practices, the process of decolonization must necessarily look more complex than simply self-rule managed from above by the colonial state or mobilized from below by nationalistic forces (cf. HYBRIDITY).

**deconstruction** A tradition of philosophical analysis and textual criticism begun by the French philosopher Jacques Derrida (1930–2004). Derrida engages the canon of Western philosophy from Plato through G.W.F. Hegel to Martin Heidegger, modern literature and art, and key social and political thinkers including Karl Marx, Sigmund Freud and Ferdinand de Saussure.

The general significance of Derrida’s work cannot be detached from the distinctive style of his writing: deconstruction works through the elaboration of particular texts, rather than creating concepts or general systems. The concepts associated with deconstruction – dissemination, parasites, pharmakon, trace and others – are like found objects, terms that turn out to have ambivalent meanings in particular textual traditions. As a ‘method’ of analysis, or a way of reading, deconstruction exposes unacknowledged implications in existing traditions. This systematically parasitical dependence of deconstruction on other texts makes the application of any particular deconstructive motif a hazardous affair of partial validity.

Derrida’s own work can be divided into an early phase of ‘critical’ deconstruction and a later phase of ‘affirmative’ deconstruction. Deconstruction first came to prominence in the 1960s and 1970s. Although Derrida is often thought of as the quintessentially ‘French’ theorist, deconstruction has been most influential in the English-speaking academy. In *Of grammatology* (Derrida, 1976), the basic lineaments of deconstructive ‘method’ are established. Derrida’s notorious claim that ‘there is nothing outside the text’ is really an interpretative rule, according to which reading is meant to follow the immanent patterns of texts rather than impose external criteria of interpretation (Barnett, 1999). In readings of Saussure, Claude Lévi–Strauss and Jean–Jacques Rousseau, Derrida identified a recurrent tendency to render writing as a secondary, contingent medium for the expression of pure thoughts properly expressed in direct speech. Derrida calls this privileging of expressive speech over the risks of mediated communication logocentrism. He claims that it embodies a deep prejudice in Western thought in favour of the ideal of a disembodied, isolated subject hooked up to the external world by the fragile and untrustworthy medium of referential language. In ‘classical’ deconstruction, this inherently normative evaluation of the relationship between speech and writing, orality and literacy, is subjected to critical analysis that leads to apparently perverse conclusions.

If writing is able to act as a supplement to the pure form of expressive speech, then this logically implies that something essential must be absent from the pure form; it turns out that far from being a mere supplement, writing is a necessary supplement to the supposedly pure form of speech. The analysis of speech and writing in *Of grammatology* exemplifies a general theme in deconstruction, whereby what is secondary, accidental or contingent is shown to be fundamental to the working of identities, meanings and systems. The point of this demonstration is not meant to be disobliging but, rather, to encourage a reordering of the terms of normative evaluation through which concepts are developed and deployed.

Derrida calls the assumption that phenomena such as meaning or identity must have singular essentialist forms the metaphysics of presence. This term indicates the relevance of deconstruction to geography’s concern with spatiality and temporality. Deconstruction is indebted to Heidegger’s argument that Western thought has consistently privileged the present tense when trying to apprehend the nature of being, or ontology. By affirming the irreducible role of writing in the expression of thought, Derrida is arguing that all those aspects for which writing or textuality stands – spatial and temporal extension, and the dimension of difference that these imply – are constitutive components of apparently free-standing entities such as the unified, self-identical subject of philosophical reason. This is articulated by one of Derrida’s most important neologisms, the notion of différence (Derrida, 1982a), which refers to the movement of spatial differentiation and temporal deferral that Derrida holds is the condition
Deconstruction first came to prominence as part of debates about postmodernism, when it was invoked as an authoritative reference point for critiques of essentialism and foundationalism in epistemology. This epistemological reading saw deconstruction externally applied to support arguments about the contingency of knowledge-claims and the constructedness of phenomena. This construal of deconstruction owed a great deal to Richard Rorty’s pragmatism. In a number of fields, such as economic geography or critical geopolitics, deconstruction is appealed to as a variant of ideology-critique to help in debunking claims of objectivity and naturalness (see also cartography, history of).

The predominant anti-essentialist, epistemological framing of deconstruction has been supplanted by the more sophisticated focus on ontological issues. Doel (1999) provides the most systematic engagement with the spatial and temporal metaphysics of deconstruction, laying out an alternative spatial grammar of mobility, relations and foldings. Post-colonialism in geography has also been heavily inflected by deconstruction. Derrida’s concern with issues of reading, interpretation and context are intimately related to a wider critique of Western historicism (Young, 1990b). And, most recently, geographers have begun to engage seriously with the ethical and political aspects of deconstruction’s treatment of themes such as hospitality, responsibility, radical democracy, cosmopolitanism and sovereignty (Popke, 2003; Barnett, 2004b, 2005).

The ethical and political turn in deconstruction indicates that what is most at stake in deconstruction is neither epistemology nor ontology per se but, rather, a challenge to rethink the inherent normativity of theoretical reasoning. Certainly, any temptation to deploy deconstructive ideas as if they were socially-theoretical concepts is best avoided, not least because Derrida’s engagement with various traditions of metaphysical reflection is almost completely devoid of any mediation by sociological or historical conceptualization that any such usage would require. In short, deconstruction might be much less new, original or disruptive than is often supposed. Deconstruction is not best thought of as either postmodernist nor post-structuralist; rather, it lays is a practice of reasoning governed by the imperative of working through inherited traditions in critical, inventive and responsible ways. Deconstruction therefore continues a tradition of enlightenment critique, but with a distinctive flourish.

**deduction** A form of reasoning which – as the reverse of the sequence deployed in **induction** – moves from the general to the particular. It takes what is known (or assumed) as given, and deduces possible consequences from those axioms. In an empirical situation – which is the normal context for the application of deductive reasoning in **human geography** – the deductions are normally expressed as **hypotheses**, statements of expectations on the basis of prior knowledge. Formal procedures are then deployed to test the validity/falsifiability of those statements (cf. ** falsification**), most of which involve the ‘scientific methods’ normally associated with **positivism**. (See also **abduction**.)

Harvey (1969).

**deep ecology** A radical form of **environmentalism** that argues that **nature** has an inherent right to exist, that humans are part of nature and that our ecological awareness comes from experiencing ourselves within nature (Devall and Sessions, 1985). Deep ecology is both a philosophy and a practice associated with the Western **environmental** **movement**. Although it draws on earlier ideas, the term emerged when the Danish philosopher Arne Naess (1973) distinguished between ‘shallow’ and ‘deep’ ecology. The former approach was seen as technocentric, anthropocentric and reformist. In contrast, deep ecology has emerged and developed as a **philosophy** that is ecocentric; advocates dismantling the dominant socio-economic systems through which humans appropriate nature; and argues for biocentric equality, so that the desire by humans to dominate nature is eliminated in favour of humans, as one species, living in nature. Humans, like other species, must respect nature’s limits and thresholds in order for all forms of life to live on a sustainable basis.

There is diversity in both the thought and practice of deep ecology. The practice includes very radical, single-issue, deep ecology organizations such as the Animal Liberation Front, which is dedicated to **animal** welfare, through **violence** and other means if necessary, and groups such as Earth First!, which was promoted as the **activist** version of deep ecology.

In addition to local site-defence groups, the philosophy has also influenced formally organized activist organizations and Green political parties in many developed countries (Luke, 2002). Within geography, while there has been more engagement with deep ecology by human geographers, Haigh (2002) advocates that deep ecology guide the teaching, research and practice of **physical geography**.

Deep ecology has been critiqued as romanticism, fundamentally flawed in its conception of non-human parts of nature having intrinsic value, and **anti-humanist** in its approach (this was a major debate in the 1980s with social ecologists led by Murray Bookchin). Deep ecology has also been critiqued for its inability to distinguish between different parts of humanity (men and women, rich and poor, different cultural beliefs and practices) and its celebration of outdoor experiences in nature, which Luke (2002) labelled ‘sports-personism’ and claimed was a potentially dangerous form of ‘**utopian** ecologism’. The danger partly arises from the lack of a transition strategy in deep ecology, other than individual action, to move from the present situation to a future deep ecology state of ‘harmony’ with nature (Luke, 2002). Despite the critiques, deep ecology has been influential and cannot be ignored. It has encouraged a wider appreciation of nature and modern humanity’s often destructive relations with it.

**defensible space** A concept associated with Oscar Newman (1972, 1996), who identified **modernist** design of high-rise buildings in ‘park-like’ settings as a key factor increasing residents’ vulnerability to **crime**. Studying crime statistics for public housing in New York City, he argued that crimes such as rape increased dramatically in anonymous interior public spaces. He argued that high-density housing can be safe if designed according to principles of defensible **space**, which allow residents to claim **territory**, provide opportunities for resident self-surveillance, reduce the stigma and isolation of public housing, and connect public housing to other safe spaces by orienting buildings to public streets rather than interior pathways. These ideas were taken up and tested more rigorously in the UK by Coleman (1985), and have been extended into situational crime prevention programs such as Crime Prevention Through Environmental Design (CPTED) and Safe Cities Programs (Wekerle and Whitzman, 1995). These more recent programmes focus on public space (rather than the semi-public
DEINDUSTRIALIZATION

spaces of public housing) and address perceptions and fear of crime as well as actual crime. The Safe Cities Program in particular emphasizes a broad community-oriented approach to problem-solving. Recent efforts to control crime through SURVEILLANCE, such as security cameras, are distinct from the concept of defensible space, which emphasizes the need to create the architectural framework to enable residents to control their own environment.

deindustrialization A sustained decline in industrial (especially manufacturing) activity and capacity (cf. INDUSTRIALIZATION). It may involve the absolute and/or relative decline of industrial output, employment and other means of production. Such changes are quite normal in the course of economic development. However, when they are linked to the declining competitiveness of industrial production to meet extra-regional, domestic and international demand within reasonable levels of employment and a sustainable balance of payments, deindustrialization represents a process of UNDERDEVELOPMENT. The causes of deindustrialization are complex. In the contemporary global economy, they lie in a combination of local circumstances and locational adjustment to global conditions. In a CAPITALIST economy, the rate of profit and its determination must lie at the centre of any explanation of these changing spatial configurations of industrial activity. (See also RUSTBELT.)

deliberative mapping The collaborative creation of MAPS by multiple authors who share a common interest or complementary expertise. Also known as ‘collaborative mapping’, ‘participatory mapping’ or ‘geocollaboration’, deliberative mapping is a form of distributed mapping supported by GEOGRAPHIC INFORMATION SYSTEMS and online software designed for group decision-making in map design, environmental planning, political REDISTRIBUTING or emergency response (MacGillavry, 2003). Collaboration can be in real time or asynchronous, over a period of days, weeks or even years (Schafer, Ganoe, Xiao, Coch and Carroll, 2005). The dialogue is both verbal and graphic, as participants at adjoining workstations or continents apart suggest applications as well as modifications. MM

democracy The term ‘democracy’ has a simple meaning: ‘Rule by the people’. But the meaning of ‘people’ and ‘rule’ are far from straightforward. The HISTORICAL GEOGRAPHY of democracy is therefore the ongoing process of finding answers to various practical problems: who should rule, how rule should be organized, and over what scope of activities. But these practical issues are internally related to questions of justification, which means that democracy is a highly contested concept in both theory and practice. As a result, the empirical analysis of democratic politics cannot avoid issues of normative democratic theory.

Modern democratic theory depends on a distinctive GEOGRAPHICAL IMAGINATION. It assumes that democracy is framed by bounded TERRITORIES, involving a nested hierarchy of SCALES contained within the NATION-STATE (see also BOUNDARY). Key thinkers of this tradition have focused considerable attention on the geographical organization of democratic politics in complex, spatially extensive territories (Dahl, 1989). The limitations of this territorial framing of democracy are increasingly subjected to critical investigation in political science (Shapiro and Hacker-Cordón, 1999).

Until very recently, there has been little explicit focus in HUMAN GEOGRAPHY on the normative questions that are at the core of debates about the relationship between democracy and SPATIALITY. This is the result of POLITICAL GEOGRAPHY’s avoidance of reflection on the normative basis of political issues. However, the 1990s saw a shift in various sub-disciplines towards investigating the entwinement of practical issues with normative issues central to democratic theory; for example, issues of participation in development geography, issues of deliberation in urban planning, and issues of citizenship in environmental studies. Aspects of democratic theory are now present across human geography (Barnett and Low, 2004).

ELECTORAL GEOGRAPHY is the sub-field in which the geographies of democracy have always been a concern. Much of this has focused on mapping distributions of votes, but recent attention has focused on developing more sophisticated, spatially sensitive explanations for voting behaviour (Agenow, 1996). The spatial organization of electoral systems effects how votes are translated into representative
majorities in liberal democracies (see liberalism). The spatial organization of formal democracy therefore has consequences for democratic outcomes in terms of basic criteria of equality and representativeness. Research on this process has broadened out to include the geographies of campaigning, party-formation and political communication. This has also involved more explicit considerations of the normative issues at stake in the traditional issues such as gerrymandering, re-districting and representation (Johnston, 1999; Hannah, 2001).

The past two decades have seen the global ‘DIFFUSION of democracy’, in the wake of the collapse of COMMUNISM in Eastern Europe, political transitions away from authoritarianism in LATIN AMERICA, AFRICA and ASIA, and the application of norms of ‘Good Governance’ in the GEOPOLITICS of Western international engagements. Geographers have investigated the degree to which the adoption of democratic forms of governance can be accounted for by specifically geographical factors (O’Loughlin, Ward, Lofdahl et al., 1998), contributing to renewed debates concerning whether democracy can only be established and sustained after various socio-economic and cultural prerequisites have been met (Przeworski, 1995). The theoretical assumptions and the practical devices through which liberal forms of electoral democracy have been circulated as the global norm have also been critically interrogated (Bell and Staeheli, 2001). Debates about democratization raise fundamental questions regarding the degree to which the norms of Western, liberal, representative democracy can and should be practically applied in non-Western contexts and deployed as normative benchmarks of critical analysis (see ethnocentrism; eurocentrism; see also Slater, 2002). The geographical mobility of democratic practices suggests that the devices through which different imperatives of democratic rule are enacted can be combined, adapted and reordered in different geographical contexts (Saward, 2003). This points to the importance of issues of temporal sequencing and spatial organization to the successful institutionalization of the complex, competing imperatives of democratic deliberation, decision-making, accountability, participation and revision (Dryzek, 2005).

Criticisms of liberal, representative democracy that assume the nation-state as the natural container of democratic politics have encouraged geographers to pay increasing attention to various alternative models of democracy. In contrast to the focus of electoral geography on the formal democratic procedures of elections, voting and parties, geographers have turned to notions of PARTICIPATORY DEMOCRACY and RADICAL DEMOCRACY to consider the diverse practices and sites where questions of accountability, CITIZENSHIP, justice and participation are contested (Young, 2000). One feature of these explorations is a commitment to thinking of democracy as more than simply a procedure for legitimizing the decisions of centralized bureaucracies. Models of deliberative democracy are now in the ascendancy in democratic theory, implying a much more active role for citizens in all facets of decision-making, as well as the extension of democratic norms to a far wider array of activities. These sorts of arguments are often associated with calls for the decentralization of decision-making and political participation to sub-national scales of regions and cities. At the same time, there is increasing attention given to emergent forms of transnational democracy (Anderson, 2002a), focusing on the degree to which systems of globalized economic and political governance can be subordinated to democratic oversight (Held, 1996). In this work in particular, there is increasing attention given to the diverse ‘agents of justice’ through which democratic justice can be pursued and secured (O’Neill, 2001), moving beyond an exclusive focus on states as the privileged containers of democratic politics (cf. Low, 2003). This emphasis on the global dimensions of democratic politics has two important implications for geographical research in these areas. First, it indicates that rather than opposing representative to participatory forms of democracy, any viable form of democratic polity is likely to combine aspects of these practices in different ways. For both practical and normative reasons, representation seems an irreducible aspect of any viable, pluralistic model of democracy. Not only do representative procedures enable the TIME–SPACE DISTANCIMATION of democratic politics, but they also embody important principles of difference and non-identity within the demos (Barnett, 2003, Ch. 1). Representation is also an unavoidable mechanism for the integration of so-called ‘mute interests’ – for example, future generations or non-human actors – which concerns with environmental futures has made a much more imperative consideration for democratic theory (Goodin, 2003). The second reason why the GLOBALIZATION of democracy is significant is that it suggests a move beyond the predominant territorial framing of the spatiality
of democracy. Rather than thinking simply in terms of the need to articulate sub-national and national scales with global scales, discussions of these topics increasingly focus on the diverse spatialities of democracy, ones which articulate territorial and non-territorial practices, scalar and non-scalar conceptualizations of space (Low, 1997). CB

demographic transition A framework that explores the historical sequence of changes in fertility, mortality, migration and age structure. This cornerstone of research in demography (see also historical demography) uses widely accessible data (typically, time series records of vital rates), proposes that stages of economic development have particular demographic signatures and suggests that population policies encourage zero population growth.

Its foundational concepts drew on French and western European experience in the nineteenth and early twentieth centuries, and described a linked reduction in mortality rates that helped to trigger sustained declines in birth rates. According to the ‘classic’ transition model (see figure), (national) populations began at a high stationary phase, with both death rates and birth rates high, and overall population growth rates low. Improvements in fresh water supply and sanitation, public health and nutrition (characteristics of the epidemiological transition) begin to support a downward trend in death rates. As this occurred at the same time as birth rates remained high, population growth accelerated during the next ‘early expanding’ phase. During the third ‘late expanding’ phase, population growth continued but annual rates of increase slowed down as the linked ‘fertility transition’ kicked in and birth rates fell in response to diverse factors including urbanization, decreased infant mortality, the changing roles of children and women in society, contraception, and new patterns of nuptuality (Sanderson and Dubrow, 2000). Finally, populations entered a ‘low stationary’ phase, where both birth and death rates are low, and natural increase is again close to zero.

Considerable research has examined the degree to which, given time, all regions of the world will exhibit vital signs and demographic mechanisms that ‘converge’ on this ideal type (Coleman, 2002). For example, across contemporary sub-Saharan Africa, there is evidence to both support the diffusion of the transition and question the transition’s assumption of universalism (see Gould and Brown, 1996). Indeed, sensitivity to both historical and spatial variations in linked demographic transitions has led to calls for a reformulation of the classic framework. Noting very high levels of ageing and below-replacement fertility across a number of more developed nations, advocates of a new and distinctive second demographic transition discuss how new links between demographic drivers are being shaped by the changing relationships between parents and children in society, new living arrangements (including increased rates of cohabitation, mixed marriages and divorce) and sexual behaviours (including later parenting and high fertility outside marriage) (see, e.g., Ogden and Hall, 2004). In turn, the rise of immigration...
(e.g. in response to below replacement fertility) may promote new modes of belonging and family strategies, and create the conditions for another distinctive transition.

**Demography** The science of human populations. For much of the preceding 400 years, the field has concerned itself with the size, distribution and composition of populations, and how changes in these are connected with the three population processes of mortality, fertility and migration (Greenhalgh, 1996). While formal demography has developed mathematical and actuarial techniques to model and project changes in population (see life table; population projection), the interdisciplinary field of population studies examines demographic change within its broader societal setting and makes use of a wide range of approaches (see, e.g., historical demography; life course). Despite its keen interest in population distribution, its interdisciplinary niche and its strong connections with sociology and economics, demography has had a relatively limited engagement with geography. Although the development of population geography between the 1960s and the 1980s and the growth of spatial demography drew attention to the study of mortality, fertility and particularly migration, many geographical analyses of issues including poverty, gender roles, social exclusion, urbanization and environmental degradation underplay population factors (but for a recent exception, see Gould, 2005).

Descriptions of changes in population size and distribution make use of empirical data on deaths, births, moves and the ages at which these events occur, mostly obtained from population censuses, social surveys or registers of population. Population growth within an area is most simply expressed through the balancing equation as follows:

\[ P_{t2} = P_{t1} + (B_{t1-t2} - D_{t1-t2}) + (I_{t1-t2} - E_{t1-t2}), \]

where \( P \) is the population size, \( B \) is births, \( D \) is deaths, \( I \) is in-migrants to an area, \( E \) is out-migrants from an area, \( t2 \) is time 2, \( t1 \) is time 1 in the past, and \( t1 - t2 \) is the time interval between time 1 and time 2. Knowledge of the ages at which vital events occur allows age-specific rates to be used to create synthetic or model populations that approximate actual age compositions of populations, and may be used to project future population scenarios (see population projection). Such stable population theory is at the basis of life tables that are used to calculate life expectancy by age, the number of survivors by age, and thus the impact of the three population processes upon the age structure, and vice versa. Armed with such data, research on changes in population growth and distribution has centred on efforts to build, critique and extend the demographic transition model; for example, through work on differentials in mortality, the onset of fertility decline and, more recently, its recovery (Bongaarts, 2002; Case and Paxson, 2005).

The field has long enjoyed an extremely close – some have argued, too close – relationship with social policy, whether at the international scale such as the League of Nations’ commissioning of the Office of Population Research’s work on transition theory in the 1940s, or in informing the US administration’s laissez-faire position on family planning at the 1984 International Conference on Population and Development, or more recently in assessing the impact of immigration policy or welfare reform measures upon the life chances of low-income family members (Büche and Frick, 2005). A good deal of research effort continues to debate new dimensions of the population–resource–well-being nexus in light of the likely global diffusion of low fertility and ageing, and the short-termism of replacement migration policies (Meyerson, 2001). Connected to this, studies in family demography describe factors behind changes in the timing and nature of decisions about marriage and partnering, divorce and household dissolution, leaving and rejoining the parental home, cohabitation, and transitioning from full-time to part-time and unpaid work (Holdsworth and Elliot, 2001). The diversification and plurality of households is a theme in work on, for example, mixed marriages, and variations in intergenerational relations and resource flows by class, gender, race and ethnicity (Gershuny, 2000). Many analyses link family demography to well-being, with an increasing emphasis upon children (Eloundou-Enyegue, 2004). Applied research includes the development of geographical information systems and geodemographic techniques; both are used by marketing firms to target launch new products and design sales areas, and by local authorities to deliver services more efficiently.
Suggested reading

density gradient The rate of falling-off in some value with distance from a central point, as with the distance-decay relationships showing land values and population densities declining away from a city centre (cf. Alonso model; von Thünen model). Such relationships are often associated with patterns of social contact, diffusion and spatial spread. Rj

dependency ratio The number of persons aged 0–14 and 65 and over, divided by the number of persons aged 15–64. This total dependency ratio assesses the dependency or reliance of one group upon another, and is one of a suite of measures summarizing age composition in a population (see also the child dependency ratio, or the number of persons aged 0–14 divided by the number of persons aged 15–64, and the aged dependency ratio, or the number of persons aged 65 and older divided by the number of persons aged 15–64). The assumptions that all persons under 15 and over 65 are (equally) dependent, and that all persons within the working ages of 15–64 are (equally) independent are problematic, and are partly based on particular ideas of work and production in capitalist societies. Other measures reflect broader interest in the links between generations. For example, the caretaker ratio divides the number of females aged 50–64 by the number of persons aged 80 and older, and informs analyses of changing care relations (Teo, 1996). Overall, these measures do help expose differences in population composition that have profound social and economic implications, including the future provision of pensions and social support, patterns of economic demand and labour supply, and gender relations. (See also ageing; population pyramid.) Ajb

dependency theory A complex body of theory with somewhat varied political orientations, presenting versions of core–periphery models that purport to explain the underdevelopment of countries in the global south as a consequence of their relationships with the countries of the global north. Central to these relationships have been forms of economic, political and cultural dependence on the products of the global north, including advanced manufactured goods, political models and sociocultural norms.

The earliest major variants of dependency theory developed in Latin America and are especially associated with the Argentinean structuralist economist Raul Prebisch, for years the head of the United Nations (UN) Economic Commission on Latin America (ECLAC) and a founder of the UN Commission on Trade and Development (UNCTAD). Prebisch presented evidence for declining long-term terms of trade for global South exporters of agricultural products and raw materials, resulting in their having to pay relatively more over time for manufactured imports from the global North (Kay, 1989, pp. 31–5). This line of argument, institutionally supported by ECLAC and UNCTAD, contradicted certain features of Ricardian, neo-classical trade theory that argued for the benefits to all countries of trade based on comparative advantage (see neo-classical economics). Structuralists thus legitimized state policies of import-substitution industrialization (ISI) that had been attempted in Latin America since the 1930s. The goal of these ISI policies was to reduce the import of expensive manufactured goods by producing such goods domestically under high protective tariffs.

While Prebisch and other structuralists quickly recognized the limits of ISI strategies (Kay, 1989, pp. 36–41), they nonetheless came under sustained attack from economists who favoured export-oriented industrialization based on comparative advantage and the maintenance of minimal tariff barriers. At the same time, more politically radical versions of dependency theory came to the fore by the 1960s, including the widely read works of Andre Gunder Frank (1967). Gunder Frank, influenced in part by the Cuban revolution, argued that only a world-wide socialist revolution — not mere shifts in state trade policies — could undercut dependency in the global South and eliminate underdevelopment, which he saw as an inevitable result of core–periphery relationships under global capitalism.

Radical dependency theories gained currency beyond Latin America in the 1970s, especially in Africa, but this decade also saw the formulation of less radical versions of the dependency thesis, including ‘dependent development’ (Evans, 1979) and world-systems analysis (Wallerstein, 1979), that more readily allowed for the possibility of some movement upwards from the global periphery. By the 1980s, however, many development
theorists claimed to see considerable problems with any sort of dependency approach (Corbridge, 1986). Nonetheless, central arguments put forward by dependency theorists continue to haunt many DEVELOPMENT debates today (Gwynne, Klak and Shaw, 2003).

desertification A term coined in 1949 to refer to an extreme form of ‘savannization’, the conversion of forest into savanna, involving severe soil erosion and the invasion of dryland plants. The Sahel drought and FAMINE of the early 1970s triggered concern about advance of the Sahara, and extensive scientific debate about bio-geo-physical FEEDBACK (the effect of land-use changes on atmospheric processes because of dust, surface reflectance or other factors). This environmental narrative had great power with policy-makers (Swift, 1996). Current understanding (e.g. in the UN Convention to Combat Desertification, 1994) distinguishes between long-term large-scale climatic processes that create desert conditions, and local causes of ecological degradation and poverty (Mortimore, 1998).

development A central keyword of twentieth-century POLITICAL ECONOMY and social policy, which can broadly refer to processes of social change or to CLASS and STATE projects to transform national economies, particularly in formerly colonized or THIRD WORLD geographies. Cowen and Shenton (1996) provide a genealogy of these conceptions of intentional and immanent development emerging from an eighteenth-century European intellectual history concerned with secularized progress in the wake of social disorder. Such a genealogy must be pluralized and grounded in intertwined spatial, natural and cultural histories of improvement, colonization, commodification, discipline, predation, government, transformation, destruction and renovation. A category that carries such enormous and variable analytical weight is inevitably contentious, and the idea of ‘development’ has always been subject to critique (Cooper and Packard, 1997), long before the efficacy of the idea itself was called into question at the end of the twentieth century, whether for its allegedly inevitable EUROCENTRISM (Escobar, 1995) or for its scepticism of the invisible hand of the MARKET (Lal, 1985). One way to frame the long history of development before the concept’s use is through four key intellectual traditions: (1) political and economic liberalism and the defence of ‘free markets’; (2) Marxist critique of class, class struggle and IMPERIALISM; (3) social Darwinist notions of evolution through racially hierarchized environments; and (4) anti-colonial defence of cultural difference and the possibility of national self-determination. These four currents have provided content, and contention, to what would be thought of as ‘development’, as well as to the technocratic and statist enterprise that came together in the wake of mid-twentieth-century DECOLONIZATION.

The narrower conception of international or intentional development came to its own after the Second World War, in an ensemble of institutions, policies, disciplinary formations and, most importantly, practices of intervention in the alleviation of POVERTY in the Third World recently decolonized nations, as they sought to steer a tenuous path through the GEOPOLITICS of the COLD WAR. Development now signified intervention by governments, rich and poor, and by an array of international institutions and organizations in CIVIL SOCIETY (Cooper and Packard, 1997). Intentional development was shaped by proximal legacies: ideas of ‘late development’ in Bismarck’s Germany and the nascent Soviet Union, inter-war arguments for state intervention either to manage CAPITALISM, as envisioned by Keynes, or to resist the destructive aspects of commodification through some form of democratic SOCIALISM (as in Polanyi, 2001 [1944]). US political scientists were crucial to the emerging doctrine of MODERNIZATION theory as a disciplinary formation in the US academy (Gilman, 2003) tied to the conceit that the right kinds of social and economic planning would bring Third World countries in line with Western capitalist norms of social transformation. Development economics and new STATE capacities fueled the Promethean visions of Third World states, many of whom used modernization theory to navigate through the Cold War, controlling diverse and often undemocratic politics, while forging shifting economies from reliance on primary-product exports to import-substitution INDUSTRIALIZATION.

This orthodoxy of modernization, statism and developmentalism was soon called into question through oppositional forces of the 1960s and early 1970s, which sought to redefine ‘development’ in more radical terms. These forces were sometimes inspired by radical anti-colonial thinkers such as Fanon...
(1963 [1961]), or they were spontaneous guerrilla or squatter movements critical of the failures of anti-colonial nationalists in power. Latin American structuralists and dependency theorists saw ‘peripheries’ revert to UNDER-DEVELOPMENT and forced stagnation through trade relations with ‘metropoles’ (see CORE–PERIPHERY MODEL and DEPENDENCY THEORY). Others turned to PEASANTS neglected by the systematic and global dumping of US grain surpluses. A series of ‘Third Worldist’ schools of development studies, along with journals such as Monthly Review and the Journal of Peasant Studies, represented this wider climate of what Emannuel Wallerstein calls the ‘anti-systemic movements’ of the 1960s (see Watts, 2001).

The 1970s saw the response from states and multilateral institutions to the oppositional movements of the 1960s, manifest in neopo- litis and forced austerity and to metropolitan banks. Development theory in sovereign states to ensure repayment realignments, allowing new forms of intervention within the development establishment. The WORLD BANK spoke of ‘basic needs’. GREEN REVOLUTION transformations reshaped agrarian geographies and associated livelihoods and expectations. Research and policy interest in the INFORMAL SECTOR intensified, while development institutions sought to integrate women in development in areas of food production and fertility. The 1970s was also a period of deepening global CRISIS and transformation in the US’s hegemonic role in relation to the geopolitics of finance, currencies and energy. The OPEC oil-price hike and the subsequent flood of Eurodollars into offshore US banks led to reckless lending and borrowing by increasingly indebted Third World countries, and the Debt Crisis of the early 1980s was ‘resolved’ through geopolitical realignments, allowing new forms of intervention in sovereign states to ensure repayment to metropolitan banks. Development theory and practice shifted abruptly into a period of forced austerity and STRUCTURAL ADJUSTMENT, justified through a reinvention of liberal economic doctrine, in what John Toye dubbed ‘the neo-liberal counterrevolution’. The onset of NEO-LIBERALISM coincided with the demise of the USSR – the massive experiment in state socialism – whose birth and death marked hopes and laments of many Leftist development thinkers and Third Worldist nationalisms, while making space to rethink anti-imperialist, democratic socialist alternatives to Cold War verities (Nove, 2005 [1983]).

By the 1990s, the focus of development had shifted to East Asia, to economies that had come through years of crisis, and to remarkable transformations in China: a kind of capitalism with Maoist characteristics, combining fast growth with piling social and environmental costs (see ASIAN MIRACLES/TIGERS). The twenty-first century has in several senses borne the continuing importance of development questions after the highpoint of neo-liberal and POST-DEVELOPMENT critiques, as well as the continued salience of its four long-term themes of LIBERALISM, MARXISM, SOCIAL DARWINISM and anti-colonial radicalism. Neo-liberalisms are now seen in relation to state interventions, imperial MILITARISM and CLASS projects of regional elites as well as their adversaries. A revival of interest in Polanyi (2001 [1944]) comes at a time when the social costs of market fundamentalism are clearer, and a key task of development geography is to track its local articulations, as Hart (2001) demonstrates in South Africa. Hart’s work exemplifies the importance of continuing to trace development processes in their spatial diversity, and in relation to development models abstracted from elsewhere. Taking the South African government’s arguments about East Asia as exemplar, Hart argues that Chinese capitalism has relied on histories of land reform and state investment in a social wage, precisely that which has been eroded in the decade following APARTHEID. This is a powerful call to a development geography engaged with concrete policy problems and popular aspirations that is also careful about tactics.

devolution The transfer of POWER or authority from one person or body to another, and specifically the transfer of governmental powers from the central or federal government to lower tiers. Devolution may involve the transfer of functions to unelected regional or local administrative bodies, but the term is more commonly used to refer to the transfer of some legislative powers to provincial elected assemblies, which are often established for the purpose.

Devolution thus involves a division of powers (administrative, judicial or legislative) between the central government and sub-national institutions. Devolution is sometimes distinguished from FEDERALISM in which the division of powers is determined by the constitution, whereas under devolution the powers are conferred by the centre, which retains the capacity to revoke them. However, the practical operations of federal and devolved systems are often similar.

The extent of devolution varies between countries, but sub-national institutions typically
have responsibility for policy fields such as planning, economic development, health care and environmental protection, while defence and foreign affairs remain the responsibility of the central state. Devolved institutions may also have revenue-raising powers. Devolution may also be ‘asymmetrical’ with some territories having more autonomy and greater power than others within the same nation-state.

Devolution has been an important state strategy for the management of territorial political and cultural differences and the political claims associated with them (Keating, 1998: cf. territory; territoriality). It has also been an important demand of territorial (especially regionalist) political movements, whether as an end in its own right or as a step towards either independence or political separation (see regionalism).

Regional devolution has been a notable feature of the political geography of the European Union since the 1970s. For example, of the six largest EU countries, different forms of regional autonomy were introduced in Spain in 1978, in France after 1982, in Italy during the 1990s and in Poland after 1999. In the UK in 1999, a devolved parliament with some tax-raising powers was established in Scotland, along with elected assemblies of more limited scope in Wales and Northern Ireland (Germany had adopted a federal constitution in 1949: see EU Committee of the Regions, 2003).

dialectic(s) The perpetual resolution of binary oppositions, a metaphysics most closely associated in European philosophy and social thought with G.W.F. Hegel (1770–1813) and Karl Marx (1818–83). In human geography, a simple example would be the following, essentially Hegelian reading of August Lösch's location theory. There:

a perfectly homogeneous landscape with identical customers, working inside the framework of perfect competition, would necessarily develop, from its inner rules of change, into a heterogeneous landscape, with both rich, active sectors and poor, depressed regions. The homogeneous regional system negates itself and generates dialectically its contradiction as regional inequalities appear. (Marchand, 1978)

This is a helpful first approximation, but the dialectic is usually deployed outside the framework of neo-classical economics that contains traditional location theory. In fact, it is a characteristic of the Löschian system that once the heterogeneous landscape has emerged, it is maintained in equilibrium rather than convulsed through transformation. As such, it is really an example of a categorical paradigm – one in which change is simply the kaleidoscopic recombination of the same, ever-present and fixed elements – rather than a fully dialectical paradigm.

The most developed dialectical paradigms in human geography have been derived from Marx's historical materialism. A formal statement of principles has been provided by Harvey (1996, pp. 48–57; cf. 1973, pp. 286–302). Its key propositions include the following:

- Dialectical thinking emphasizes processes, flows and relations.
- The formation and duration of systems and structures is not the point of departure (these ‘things’ are not treated as givens) but, rather, the problem for analysis: processes, flows and relations constitute – form, shape, give rise to – systems and structures.
- The operation of these processes, flows and relations is contradictory, and it is the temporary resolution of these contradictions that feeds into the perpetual transformation of systems and structures. All systems and structures thus contain possibilities for change.
- Spaces and times (or, rather, ‘space–times’) are not external coordinates but are contained within – or ‘implicated in’ – different processes that effectively produce their own forms of space and time.

Particular importance is attached to the identification of contradictions. Formally, a contradiction is a principle that both (i) enters into the constitution of a system or structure, and also (ii) negates or opposes (‘contradicts’) the stability or integrity of that system or structure.

These principles seem abstract when set out in this form, but they have been used to considerable analytical effect by Harvey in his explorations of the contradictory constitution and restless transformation of capitalism as a system of commodity production: hence his insistence on the crucial, dialectical concept of ‘creative destruction’. Harvey wries this to the dialectical production of space itself (see Barnes 2006a; Sheppard, 2006a). Indeed, space has occupied centre-stage in many dialectical geographies, but several of these owe as much
to Lefebvre’s reading of Marx as they do Harvey’s: hence Soja (1980, 1989) proposed a ‘socio-spatial dialectic’ (see also TRIALECTICS) and Shields (1999) described Lefebvre’s work as a ‘spatial dialectics’. Other writers, indebted in different ways to different historical materialisms, have shown how other geographical concepts may also be approached dialectically: thus Pred (1984) emphasized the dialectics of \textit{place} and practice; Mitchell (2002a) traced a series of ways in which \textit{landscape} may be interrogated as a dialectical formation; and Castree (2003b) examined the prospects (and problems) of treating what he called ‘\textit{Nature} in the making’ dialectically.

In Harvey’s own writings, as elsewhere, dialectics functions as both a mode of explanation and a mode of representation (Castree, 1996). \textit{Representation} is not confined to writing, of course, and there has been considerable interest in combining the textual and the visual in the tense constellations of what Marxist cultural critic Walter Benjamin called the \textit{dialectical image}. Historical materialism is rich with close readings of Marx’s canon – attending not only to what he said but how he said it – and it was famously claimed that Marx’s words are ‘like bats: one can see in them both birds and mice’. In human geography, however, this attentiveness to the slippery subtleties of language and to the powers released by words has occasioned a series of reflections that have taken many critics a considerable distance from Harvey’s own base in historical materialism. Thus Olsson (1974) argued that the categorical paradigm fails to recognize the interpenetrations of form and process, subject and object, so that its propositions reveal more about the language we are talking in, whereas ‘statements in dialectics will say more about the worlds we are talking about’. Olsson’s subsequent work has taken him far from Marx and into a sustained interrogation of Western philosophical thought (Olsson, 1980, 1991, 2007). To be sure, ‘words’ and ‘worlds’ are connected, as Olsson (and for that matter Harvey) constantly accentuate, and in order to explore the ways in which they are folded into one another, a number of human geographers have made two further moves. One has been to follow the linguistic turn in the humanities and social sciences, and so challenge the metaphysics of binary oppositions on which classical dialectics depends (Doel, 1992, 2006; see also \textit{deconstruction}). Another has been to take seriously Harvey’s emphases on materiality, practice and transformation, but to develop these through an avowedly non-representational theory. Here too, the accent is on practices, and on the provisional and the incomplete, but Whatmore (1999b, p. 25; see also 2002a) insists that dialectical reasoning is ‘insufficiently radical’ to convey the sensuous openness of ‘world-making’: there is thus a studied refusal to render processes through binary oppositions or to convene them within a plenary totality. But some perceptive critics have wondered whether, in practice, this agenda (its ‘relational ontology’) really is so different from the approach practiced by Harvey and others (Demeritt, 2005).

**dialectical image** A leitmotif in the work of Walter Benjamin, the dialectical image is best described as an aesthetics of historical montage, or as a method for disrupting a linear or progressivist logic of history and historical understanding. Opposed to all forms of teleology and totality, the dialectical image rests on a spatio-temporal paradox. On the one hand, all \textit{images} must be torn from their immediate contexts and their chronological movement ‘frozen’ in order to become legible. On the other, DIALECTICS, in both the ancient sense of continuous disputation and the Marxian theoretic of contradiction, works to ensure constant mobility and mutation. So understood, the dialectical image reconfigures the relationship of the past to the present. Refusing all temporal continuity in which the present illuminates the past or the past casts its light on the present, the dialectical image constitutes the scene in which \textit{time} and \textit{space} are out of joint; in which the ‘then’ and now’, like the ‘here’ and ‘there’, combine in an explosive flash or ‘constellation’. From this emerges a cognitive shock, without which rigorous conceptual thinking cannot occur.

Benjamin (1973, 1999); Buck-Morss (1989); Dubow (2007).

**diaspora** A scattering of people over space and transnational connections between people and places. The term was first used to describe the forced dispersal of the Jews from Palestine in the sixth century BCE, and often continues to refer to forced migration and exile. More recently, and particularly since the 1990s, diaspora studies have come to encompass
wider notions of transnational migration, resettlement, connection and attachment, often closely associated with post-colonial and ‘new ethnicities’ research (see TRANSNATIONALISM). For Kalra, Kaur and Hutnyk (2005), there is a broad distinction between the use of diaspora as a descriptive tool and mode of categorization (including lists of various criteria that characterize diasporas) and more critical understandings of diaspora as a contested process. Whilst some accounts identify different types of diaspora, including victim, labour, trade, imperial and cultural diasporas on a global scale (Cohen, 1997), other studies theorize diaspora and its implications for understanding space, IDENTITY, CULTURE and the politics of HYBRIDITY (including Hall, 1990; Kalra, Kaur and Hutnyk, 2005). Rather than analyse diaspora solely in terms of RACE and ETHNICITY, geographers and others working across the humanities and social sciences have explored the GENDER, CLASS and sexual spaces of diaspora. Geographers have also stressed the importance of studying the grounded politics of diaspora (including Mitchell, 1997b). Both the conceptual study of diaspora and the substantive study of different diasporas develop critical perspectives on GLOBALIZATION, NEO-LIBERALISM, MULTICULTURALISM and COSMOPOLITANISM.

Both ideas about diaspora and studies of particular diasporas are inherently geographical, revolving around space and PLACE, MOBILITY and locatedness, the NATION and transnationality. The diasporic lives of transnational migrants, for example, are often interpreted in terms of ‘roots’ and ‘routes’ (Clifford, 1997). Whilst ‘roots’ might imply an original HOMELAND from which people have scattered, and to which they might seek to return, a focus on ‘routes’ complicates such ideas by tracing more mobile, transcultural and deterritorialized geographies of migration and resettlement. As Paul Gilroy explains, the spatialities of diaspora represent ‘a historical and experiential rift between the locations of residence and the locations of belonging’ (2000b, p. 124). A wide range of research explores diasporic attachments to homelands that might be remembered, imagined, lost or are yet to be achieved, and the political, economic and cultural materialization of such attachments through political activism, the transfer of remittances and diverse cultural practices. Other research unsettles the idea that people living in diaspora are bound to a homeland or nation of origin and identification. Avtar Brah, for example, proposes the notion of ‘diaspora space’ to encompass the ‘intersectionality of diaspora, BORDER, and dis/location as a point of confluence of economic, political, cultural and psychic processes’ (1996, p. 181). As Brah explains, ‘diaspora space as a conceptual category is “inhabited” not only by those who have migrated and their descendants but equally by those who are constructed and represented as indigenous. In other words, the concept of diaspora space (as opposed to that of diaspora) includes the entanglement of genealogies of dispersion with those of “staying put”’ (p. 181).

DIFFERENCE

Suggested reading
Brah (1996); Clifford (1997).

difference The concept of ‘difference’ has become an increasingly prominent concern in GEOGRAPHY over the past two decades. Geographers have looked at how socio-spatial boundaries of inclusion and exclusion are produced on the basis of categories such as RACE, CLASS, GENDER, SEXUALITY OR DISABILITY. Most agree that these and other such categories are socially constructed. This is not to say that differences do not exist or are illusory but, rather, to point out that the ways in which we categorize ourselves and others are the result of social practices. Further, these socially constructed differences have very real political effects. As Audrey Kobayashi (1997, p. 3) writes, ‘The concept of difference allows the social creation of categories of people subordinate to a dominant norm, and allows the continuation of cultural practices that reinscribe difference as differential values placed upon human life.’

In that difference arises from social practice, it is also spatial. David Harvey (1996) argues that SPACE and TIME work to individuate and identify people through the production of differences along multiple axes. In other words, geographically inscribed inequalities position people and groups differently in relation to political, cultural, ecological and economic RESOURCES. Spatial practices such as SEGREGATION and the POLICING OF BORDERS work to enforce and consolidate difference. As David Delaney (1998) shows in his work on race, LANDSCAPE AND LAW, the complex legal geographies of PROPERTY and public/private distinctions are inseparable from the relations of POWER and domination that are associated with difference. This means that some people have more access to RIGHTS in certain spaces than others.

While ideas about difference often work to delimit hierarchies and inequalities, difference
is also a powerful element of identity politics. Race, class, gender, sexuality and other differences can provide the basis for solidarities and resistance. Arguments that point out the constructed nature of such categories and that highlight the divisions within groups (such as racial differences within feminist movements, or class differences within racial politics) can seem to threaten the basis of political struggles forged around identities such as ‘Black’ or ‘Woman’. In response, some feminists have adopted ‘strategic essentialism’, choosing to emphasize the commonalities across women’s experiences in order to unite women for political purposes.

Difference poses political problems for those who wish both to value diversity and to dismantle the structures of discrimination and oppression that scaffold ideas about difference. The question of how to recognize and make space for the very real effects of difference, or positionality, and at the same time to dismantle hierarchies based on difference is of ongoing concern to political theorists and geographers. Iris Marion Young (1990a), for example, has advocated for the celebration of diversity within an overarching political unity. Such a project is not, however, without its difficulties in the context of ever shifting axes of difference and alliance.

diffusion The spread of a phenomenon (including ideas, objects and living beings) over space and through time. There is a long tradition of diffusion studies in American cultural geography, most closely associated with the work of Carl Ortwin Sauer (1889–1975) and Fred B. Kniffen (1900–93). According to Sauer (1941), it was Friedrich Ratzel (1844–1904) who ‘founded the study of the diffusion of cultural traits, presented in the nearly forgotten second volume of his Anthropogeography’ published in 1891 (see ANTHROPOGEOGRAPHY). In Sauer’s view, diffusion – ‘the filling of the space of the earth’ – was a ‘general problem of social science’: ‘A new crop, craft or technique is introduced to a culture area. Does it spread, or diffuse vigorously or does its acceptance meet resistance?’ The specific contribution of geography was to reconstruct diffusion pathways and to evaluate the influence of physical barriers (Sauer, 1952; Wagner and Mikesell, 1962). Both tasks were pursued by various members of the Berkeley school, but they reappeared in a starkly different guise in the much more formal study of innovation diffusion inaugurated by Torsten Hagerstrand (1916–2004).

One of Sauer’s closest associates introduced Hagerstrand’s Swedish monograph to Anglo-American geography: ‘No one who essays in the future to interpret the distribution of culture elements in the process of diffusion can afford to ignore Hagerstrand’s methods and conclusions’ (Leighly, 1954). Even so, it was some fourteen years before an English translation of Hagerstrand’s Innovation diffusion as a spatial process appeared (Hagerstrand, 1967; see Duncan, 1974). Hagerstrand’s work had two catalytic consequences: it set in motion the frozen worlds of spatial science, and it opened the door to sophisticated computer modelling of spatial processes. The theoretical structure of his original model is shown in the figure. An interaction matrix provides the contours of a generalized or mean information field, which structures the way in which information circulates through the population in a regional system. These flows are modulated by physical barriers and individual resistances, which together check the transformation of information into innovation and so shape the successive diffusion waves that break on to the final adoption surface.

Most immediate discussion focused on the operationalization of the model – on the use of simulation methods, the comparison of observed and predicted patterns of adoption, and the detection of a localized neighbourhood effect. Within this modelling tradition, the most important developments included the following:

- A formalization of the mathematical relationships between the structure of the mean information field and the form and velocity of diffusion waves, revealing the connections between different distance-decay curves and the classic neighbourhood effect (although it is scarcely surprising that a distance-bound interaction matrix should generate a contagious pattern of adoptions).
- A demonstration that the Hagerstrand model is only a special instance of the simple epidemic model, and the subsequent derivation of more complex epidemic models, particularly through the remarkable contributions of Cliff, Haggett, Ord and Versey (1981), whose replication of a range of ‘spatial processes’ (see process) confirmed:
the recognition of hierarchical diffusion, typically through central place systems, and frequently operating alongside the distance-bound, contagious diffusion of the classical model (Hudson, 1969; Pedersen, 1970);

- the incorporation of rejection and removal processes and the modelling of competitive diffusions (Webber, 1972).

These changes entailed a move away from simulation techniques towards more analytical methods, which have been of immense importance in the increased traffic between epidemiology and medical geography (see disease, modelling of). This is now the major focus of diffusion theory in human geography, although spatial models of information circulation and innovation diffusion are important in marketing research too.

Haggett (1992) claimed to see parallels between Sauer's original prospectus and the contemporary modelling of disease, particularly his use of 'controlled speculation' and his focus on 'hearths and pathways'. Ironically, however, it was precisely these features that caused diffusion theory to fall from grace in most other areas of human geography. There were several brilliant studies that wired diffusion into larger social transformations (e.g. Pred, 1973; Blaikie, 1975), but these were the exception to a cascade of studies using available data sets merely to 'fit' or 'test' diffusion models. Just ten years after the translation of Hägerstrand's magnum opus, Blaikie (1978) could speak of a 'crisis' in diffusion research, which he said arose from its preoccupation with spatial form and space–time sequence, while Gregory (1985) attributed the 'stasis' of diffusion theory to a pervasive unwillingness to engage with social theory and social history to explore the conditions and the consequences of diffusion processes. Critics argued that the spatial circulation of information remained the strategic element in most applications of the Hägerstrand model and its derivatives, and while flows of information through different propagation structures and contact networks were exposed in more detail, the primacy accorded to the reconstruction of these spatial pathways obscured a crucial limitation of the Hägerstrand model: it operated within what Blaut (1977) called a 'granular region', 'a sort of Adam Smithian landscape, totally without macrostructure'. In particular:

(1) The Hägerstrand model begins with a pool of 'potential adopters' and does not explain the selective process through which they are constituted in the first place. This suggests the need for a model of biased innovation, where (for example) class or gender circumscribes access to innovations. 'Non-diffusion' is then not a passive but an active state arising directly from the structures of a particular society (Yapa and Mayfield, 1978). Critiques of this sort required diffusion theory to be integrated with fields such as political economy and feminist geography that pay attention to the social as well as the spatial.

(2) The Hägerstrand model assumes a 'uniform cognitive region' and does not explain the selective process through which information flows are interpreted. This matters because 'resistance' to innovation is not invariably a product of ignorance or insufficient information: it may signal a political struggle by people whose evaluation of the information is strikingly different to that of the 'potential adopters'. Critiques of this sort required diffusion theory to be reconnected to a more general cultural geography (Blaut, 1977).

These critiques served largely to divert attention to other projects, however, and there has been little advance in the architecture of diffusion theory in recent years. Interest in the detailed reconstruction of specific diffusion sequences as key moments in processes of economic and cultural transformation has continued in cultural–historical geography and environmental history (e.g. Jordan, 1993; Overton, 1996), and there is also a growing interest in the circulation of information, including the transmission of scientific knowledge and the formation of creative economies (Kong, Gibson, Khoo and Semple, 2006). But these enquiries rarely refer to, let alone rely on, classical diffusion theory. The tension between diffusion modelling on the one side and cultural-historical and politico-economic studies of diffusion on the other (and the versions of human geography that each represents) is exemplified by the study of AIDS. Mapping and modelling the spread of the disease has been a major focus of geographical enquiry, but this has been undertaken largely in isolation from studies of its social and cultural geography (cf. Brown, 1995). It is in the space between these two intellectual traditions that diffusion theory currently languishes, but some small steps
towards bridging the gap have been made in studies of disease diffusion and war (e.g. Smallman-Raynor and Cliff, 2004).

Blaikie (1978); Blaut (1977); Haggett (1992).

**digital cartography** The use of numerical coding, electronic media and digital computers to collect, manipulate, manage and display geographical data. Coined in the 1970s, the term has largely replaced the older rubric ‘computer-assisted cartography’, because almost all production cartography is now computer-assisted. ‘Digital cartography’ seems destined for obsolescence insofar as most geospatial data are now ‘born digital’; that is, originally captured as numbers using a GLOBAL POSITIONING SYSTEM (GPS) receiver, aerial photogrammetry or REMOTE SENSING, rather than converted from an existing map image by scanning or a process of electronic tracing known as DIGITIZING. In this sense, geographical data acquired by updating, transforming or otherwise enhancing the attributes (descriptions) of cartographic objects such as street segments and land parcels are also born digital. Because hard-copy, analogue maps have become more the exception than the rule, ‘digital cartography’ seems likely to survive only when writers need an opposite for ‘analogue cartography’. Even so, born-digital materials, especially useful because they are readily searchable and easily updated, challenge conventional practices of map preservation and copyright (Varian, 2005).

As an endeavour, digital cartography is closely related to GEOGRAPHIC INFORMATION SYSTEMS (GIS). In general, the former focuses on data acquisition, data management and the generation of reproducible images, while the latter emphasizes data retrieval and specialized analysis. These overlapping disciplines share a common interest in automated map generalization and the display of terrain data. In addition, digital cartography has a dynamic, interactive component linked to scientific VISUALIZATION and computer animation. Other shared concerns include standardized terms and definitions, flexible exchange formats, efficient methods for ensuring reliability, and the development of metadata describing a file’s origin, contents and fitness for use (Noguerrases-Is, Zarazaga-Soria, Lacasta, Bezur and Muro-Medrano, 2004).

As with GIS, digital cartography recognizes two principal types of data, RASTER and VECTOR. Examples of raster data include landcover data acquired from space with a multi-spectral scanner, digital elevation models (DEMs) consisting of surface elevations sampled for a grid with rows and columns spaced 30 m apart, and images scanned from historical TOPOGRAPHIC MAPS and nautical charts. The spatial quality of a raster data set is described by the spatial resolution of the sensor or scanner. By contrast, vector data rely on lists of point coordinates to describe the shape and position of BOUNDARY lines, streets and other linear features, as well as lists of linkages or adjacencies to specify the boundaries of polygons representing, for example, counties or CENSUS TRACTS. In addition, attribute data describe the type of feature, its name or identifying number, and specialized characteristics such as the population of a CENSUS TRACT or...
the width and left- and right-hand address ranges of a street segment.

Each format has particular advantages. Maps in raster format, for instance, are well suited for print-on-demand distribution as well as dissemination over the INTERNET (Evans and Vickers, 1995). By contrast, vector data are especially useful for creating map displays at different scales on diverse projections (see MAP PROJECTION). Mathematical formulae afford ready conversion between spherical and plane coordinates or from one projection to another. Indeed, tailored map projections that control distortion for a region of interest or provide insightful views, including dynamic oblique views or flyovers, are a prime asset of digital cartography.

Digital cartographic research has also produced ALGORITHMS for map generalization and map labelling, both of which support the dynamic, interactive change of scale for street maps, topographic maps and electronic atlases. Generalization is especially relevant for maps displayed at scales smaller than that for which the data were originally acquired (McMaster and Shea, 1992). Because map symbols are more likely to overlap as scale decreases, a generalization algorithm must first identify areas where overlap will occur and then avoid aesthetically awkward (and sometime confusing) graphic conflict by suppressing less important features or shifting them apart – one of several ethically responsible trade-offs that human mapmakers call 'cartographic license' (Li and Su, 1995). Generalization must also smooth out intricate coastlines and streams with tight meander loops, both of which can yield ambiguous and unappealing blobs at substantially reduced scales. Automated map labeling is similar to map generalization insofar as the algorithm must determine potential conflict between the allegedly ideal positions of map labels (Zoraster, 1997). If the conflict cannot be resolved by moving one or more labels to a less desirable location, the algorithm might need to leave a feature unlabeled or use a thin leader line to link a symbol with a label that cannot be adjacent. More straightforward is the attachment of text to curved features such as roads and streams.

Another common display task in digital cartography is the realistic viewing of digital elevation models. Typical strategies include low-angle oblique views, which require a geometric transformation as well as the identification and suppression of symbols where the surface is hidden from view (De Floriani and Magillo, 2003) and the addition of shadows, or hill shading, in areas not illuminated by a hypothetical light source located in the upper left or upper right (Tuhkanen, 1987). More intriguing are maps formed by draping satellite imagery, land-cover classifications or topographic symbols over obliquely viewed digital elevation models (Banerjee and Mitra, 2004).

Although digital cartography has largely displaced its non-electronic counterpart as the principal means of acquiring and storing geospatial data, paper maps thrive in diverse ways: in newspapers, magazines, atlases and geography textbooks; as mass-marketed way-finding and recreation maps; and as customized, one-off artefacts downloaded over the Internet (Peterson, 2003) or created using commercial, off-the-shelf mapping software (Longley, Goodchild, Maguire and Rhind, 2005, pp. 157–75). Everyday experience suggests, not without irony, that the majority of paper maps nowadays are specially tailored renderings based on digital data and produced on a laser or ink-jet printer.

digitizing The process of converting IMAGES, TEXTS, MODELS, MAPS, sounds and data into digital and computer readable forms, with an expectation of 'value added' but a risk of information loss. A paper map is easily digitized into bitmap or JPEG format using a conventional, desktop scanner. However, the user may be disappointed by the result. First, the original image will be converted into a series of discrete (RASTER) pixels. The blocky nature of these will be evident in words or labels copied from the original document; the severity will depend on the resolution of the scanner (its dpi – dots per inch). Second, loading the image into a GEOGRAPHIC INFORMATION SYSTEM will not leave it positioned correctly with other maps and data on screen. The reason is that although the digital image may show a map, no information has been encoded such that the computer can interpret it graphically. Providing a ‘world file’ assigns GEOCODES to the corners of the image and therefore locates it. Yet, if the user’s goal is to select all schools within a certain distance of a major road, for example, then s/he will still be left wanting: the original map has been digitized ‘en masse’ without encoding the two specific features of schools and roads.
The general point is that digitizing may appear straightforward, but producing an outcome that is fit for purpose requires more careful thought. For example, it is easy to scan a manuscript and therefore archive it in an online depository. But unless some metadata about the document are also provided (year of publication, title, abstract etc.), then it will be hard for potential users to search the depository and extract what they are looking for. It may also be beneficial to convert the scanned image using text recognition software, permitting all documents to be searched for key words. However, this all takes time and money, as well as the development of standards and protocols to ensure consistency in how information is stored, catalogued and updated — such as those developed for the JSTOR scholarly journal archive (www.jstor.org) that allow searching of the author, title, abstract and/or full text for all or a subset of the journals archived, for all or particular dates, and for all or specific types of journal content (e.g. article, review or opinion piece) (Schonfeld, 2003).

There is also the issue of error management. Using manual digitizing tables and software to capture the geographies of schools and roads from a paper map assumes that the map is of reasonable quality, having not shrunk or stretched, and requires concentration from the person digitizing who may easily make mistakes (from a slight hand shake or from fatigue or boredom!). A lack of attention could lead to road sections that do not meet (an undershoot) or the creation of a new spur when the road is drawn past the intended intersection (an overshoot). If not detected, the errors could propagate and lead to misleading analyses of the data concerned.

Digitization is always a change to the original. Whether it matters depends on the nature of the change and how the digital version is applied. It could be argued that MP3s are inferior to vinyl records because they have a lower frequency range. But then have you ever tried to carry a thousand seven-inch singles?

disability Conventionally understood as the state of being physically and/or mentally different from some assumed ‘norm’ of human corporeal and/or psychological functioning, the term applies to people with an impairment that supposedly limits their ability to perform activities in the manner taken as ‘normal’ for a human being. Disability is often framed negatively, couched as ‘loss’ (e.g. of a limb or vision) or ‘lack’ (e.g. of mobility or reasoning skills), with scant attention paid to the experiences and aspirations of the people affected.

Proponents of the medical model of disability stress the apparently ‘damaged’ body or mind of an individual, and invite a personal narrative of ‘tragedy’ followed by ‘heroic’ efforts at self-adjustment (Golledge, 1997). Those of the social model stress not the individual but, rather, a wider society that fails to accommodate impairment, thus embracing a critical stance on the underlying ableism of a non-disabled society (Chouinard, 1997). The latter model, casting light on ‘disabling social and environmental barriers’ (Barnes and Mercer, 2004, p. 2; emphasis added) and advocating a critical ‘politics of access’, is inherently geographical in its alertness to the social and physical placing of disabled people within non-disabled settings. This model also examines both the political-economic forces impacting upon disability, as in the discriminatory dynamics of labour and housing markets, and the deeper roots of oppression occasioned by the stigmatization of ‘imperfect’ bodies (Hahn, 1989). It has itself been criticized for remaining too distanced from embodied realities, and thereby neglecting subjective experience as revealed in personal stories of pain, fatigue, rejection and simply ‘getting by’. Some theorists hence call for a third way, a biosocial model, allowing bodies and experiences into the picture while still retaining the critical sharpness of the social model (Watson, 2004).

These debates have played out within geographical research on disability (Hall, 2000b), which has become a recognizable sub-field exemplified in review articles and edited book collections (Park, Radford and Vickers, 1998; Butler and Parr, 1999). Early work considered the wheelchair-user or visually impaired person negotiating the environmental obstacle course of streets, curbs and buildings fronted by steps (Golledge, 1993; Vujakovic and Matthews, 1994). The focus upon ‘stairs’ was then supplemented by a concern for ‘stares’ (Pain, Burke, Fuller and Gough, 2001, p. 177), so that the issue becomes not just physical accessibility but also the extent to which disabled people are marked as different, fundamentally unwanted and ‘out of place’ in public space (Butler and Bowlby, 1997). The broader context of ‘disabling environments’ here attracts critique, implicating architects,
planners and building control officers (designers and ‘the state’) for producing spaces that effectively ‘lock out’ disabled people (Imrie, 1996). The longer-term historical perspective reveals how modern capitalism has initiated an ongoing process of spatially marginalizing disabled people from meaningful economic roles and the normal rounds of social reproduction (Gleeson, 1999). Other geographical enquiries now use qualitative methods such as in-depth interviewing to excavate the experiential dimensions of being ‘out of place’, detecting how the axes of disability, class, ethnicity, gender and sexuality meld together in (the enduring of) exclusionary spaces.

Disability geography deals with both physical and mental impairments, where the latter entail both people with mental health problems (the ‘mentally ill’ in a medicalized vocabulary, including the ‘depressed’, ‘schizophrenic’ etc.) and people with learning or intellectual disabilities (the ‘mentally handicapped’ or ‘mentally retarded’ of now disfavored vocabularies). There is a vibrant tradition of mental health geography (Smith and Giggs, 1988), exploring spatial–epidemiological subjects as well as looking at both the emergence of the ‘lunatic asylum’ and, more recently, processes of ‘deinstitutionalization’, ‘community care’ and the sites of everyday survival today for people with mental health problems (see contributions to Philo, 2000c). Less extensive is work on geographies of intellectual disability, although historical and contemporary studies can be identified (see contributions to Metzel and Philo, 2005). There is potential for building theoretical, substantive and ethico-political bridges between the different strains of disability geography tackling physical and mental difference, and perhaps too with parts of health geography exploring the circumstances of people with long-term chronic illness (Moss and Dyck, 2002). disciplinary power A form of power analysed in the work of Michel Foucault (1926–84) that in his analysis follows from classical sovereignty. Foucault claims that power is dispersed throughout society rather than coming from a centralized source, and that is therefore important to analyse it within institutional and social practices. Disciplinary power emerged in Foucault’s published works with Discipline and Punish (1976), but was also analysed in his earlier lectures at the Collège de France that are now being published (see, e.g., Foucault, 2003 [1999], 2006 [2003]).

While sovereignty may showcase its power through individual events of spectacular violence, such as the fighting of battles or the torture of attempted regicides – like the gruesome description of the measures meted out to Damiens at the beginning of Discipline and punish – discipline works in an entirely other way. Power is constantly exercised, over the smallest transgression, with repetition, certainty and consistency, key elements in establishing control. Its model is the modern army, with the training of individual bodies into collective ones, a process that Foucault describes as ‘dressage’. The mechanisms can be found in schools, hospitals, factories and prisons. The model of spatial organization in a town affected by the plague is another of Foucault’s recurrent examples, which he finds taken to its ideal form in Jeremy Bentham’s plan for the panopticon.

A number of key themes emerge in Foucault’s analyses: the control of the body and its ritualized training and conditioning; the continuous nature of the exercise of disciplinary power; the control and partitioning of time – particularly illustrated by the modern mechanized factory – and spatial organization and distribution. Spatial control works both on the level of architectural or urban planning, and on the ordering of individual bodies. Discipline is a distribution of bodies, of their actions, of their behaviour: a spatial strategy and analysis. These spatial strategies can be understood as enclosure or confinement; subdivision or partitioning of this space; designation of a purpose or coding to these sites; and classification or ranking of them. These spaces of power have their concomitant knowledges, which Foucault designates by the power–knowledge relation in a series of pairings: ‘tactics, the spatial ordering of men; taxonomy, the disciplinary space of natural beings; the economic table, the regulated movement of wealth’ (1976a [1975], pp. 148–9).

In Foucault’s early work on sexuality (1978 [1976], 2003 [1999]), he utilized and developed these ideas about disciplinary power, and analysed how power over life itself could be understood as biopower. In his later writings on governmentality, Foucault developed an understanding of how liberal governments tried to govern as little as possible and to open up spaces for the circulation of goods, people and wealth (see liberalism). Although many
have found Foucault’s work on power generally unremittingly bleak, the critique of individual agency and the analysis of the process by which SUBJECTS are formed – a process that Foucault calls **assujettissement**, meaning both subject-formation and subjectification – have been extremely influential.

**discourse** A specific series of representations and practices through which meanings are produced, identities constituted, social relations established, and political and ethical outcomes made more or less possible. Although different fields in the HUMANITIES and social sciences have worked with varying accounts of discourse, all grow out of the decades of debates about **LANGUAGE**, interpretation and understanding in the natural and social sciences (Howarth, 2000). As such, discourse is a concept that departs from the traditional PHILosophy of language’s relationship to the world. Instead of seeing the world as independent of ideas about it, with language transparently reflecting a pre-existing reality, theories of discourse understand reality as produced via practices of interpretation deploying different modes of representation.

Although philosophically well established, especially in POST-STRUCTURALISM, discourse remains controversial in the social sciences. Those employing the concept are often said to be claiming that ‘everything is language’, that ‘there is no reality’ and that, consequentially, a general inability to take a political position and defend an ethical stance abounds. These objections demonstrate how understandings of discourse are bedevilled by the view that interpretation involves only language, in contrast to the external, the real and the material. These dichotomies of **IDEALISM/MATERIALISM** and **REALISM/idealism** remain powerful conceptions of understanding the world. In practice, however, a concern with discourse does not involve a denial of the world’s existence or the significance of materiality. This is well articulated by Laclau and Mouffe (1985, p. 108): ‘the fact that every object is constituted as an object of discourse has *nothing to do* with whether there is a world external to thought, or with the realism/idealism opposition . . . What is denied is not that . . . objects exist externally to thought, but the rather different assertion that they could constitute themselves as objects outside of any discursive condition of emergence.’ This means that while nothing exists outside of discourse, there are important distinctions between linguistic and non-linguistic phenomena. There are also modes of **REPRESENTATION** that are ideational though strictly non-linguistic, such as the aesthetic and pictorial. It is just that there is no way of comprehending non-linguistic and extra-discursive phenomena except through discursive practices.

These philosophical debates are implied by different uses of discourse even when they are not overtly discussed. They lead to an appreciation of the fact that *discourses are performative*. This means that although discourses have variable meaning, force and effect, they constitute the ‘objects’ of which they speak and produce notions of ‘the social’ and ‘the self’ (see **PERFORMATIVITY**). The meanings, identities, social relations and political assemblages that are enacted in these performances combine the ideal and the material. As a consequence, appreciating that discourses are performative moves us away from a reliance on the idea of (social) **construction** towards **materialization**, whereby discourse ‘stabilizes over time to produce the effect of boundary, fixity and surface’ (Butler, 1993a, pp. 9, 12).

The performativity of discourse calls attention to the **discursive formations** that are produced over time by the stabilization of some interpretations at the expense of others. Discursive formations – such as **NEO-LIBERAL** notions of ‘competitiveness’ (Schoenberger, 1998), **GENTRIFICATION** and the racialization of Puerto Rican youth in Chicago (Wilson and Grammenos, 2005) or **COLD WAR**-derived GEO-POLITICAL discourses of ‘danger’ in Central Asia (Megoran, 2005) – are the culmination of discursive economies at work. In a discursive economy, investments have historically been made in certain interpretations; dividends can be drawn by those interests that have made the investments; representations are taxed when they confront new and ambiguous circumstances; and participation in the discursive economy is through social relations that embody an unequal distribution of power.

Within HUMAN GEOGRAPHY, the use of the concept of discourse can be characterized by a number of dimensions, though by no means would all scholars would accept every one of them:

- **Discourses are heterogeneous**: discourses are not the product of a single author or institution, and neither are they confined to literary texts, archives, scientific statements or political speeches. They come to have a dominant form over time, but they never
Discourses thereby shape the contours of the taken-for-granted world, naturalizing and universalizing a particular subject formation and view of the world. Theories of discourse have thus greatly enlarged the interpretive horizon of human geography. Insofar as critical human geography is concerned with the connections between power, knowledge and spatiality, discourse will be a vital concept. Discourse has also altered the self-understanding of the field. It has revivified the history of geography in which ‘great men’ or ‘paradigmatic schools’ have given way to a concern with the discursive production of geographical knowledge. It has made obvious the complicity of human geography in colonialism and imperialism (see post-colonialism) and the way in which traditional geographical knowledge effaced the contribution of non-Western subjects (Barnett, 1998). Theories of discourse have also played an important part in exposing the asymmetries of power that are inscribed within contemporary geographical discourses (notably ethnocentrism and phallocentrism), elucidating the role of rhetoric – and of poetics more generally – in legitimizing intellectual practice (Crush, 1991) and in allowing ideology to congeal as ‘unexamined discourse’ (Gregory, 1978a).

Foucault (1984); Howarth (2000).

**DISCOURSE ANALYSIS**

**discourse analysis** The analysis of discourse; methodologies for studying the production and meaning of discourses. Discourse analysis involves a wide array of approaches to the construction and interpretation of meaning. These approaches understand language as a social practice, and are concerned with language use beyond the semantic units that are the domain of linguistics. The differences between the approaches to discourse analysis depend on the extent to which they (a) understand themselves to be a formal methodology (hence the sometimes capitalized term ‘Discourse Analysis’) as opposed to a critical interpretative approach; and (b) the extent to which the formal components and properties of linguistic representations, as opposed to the social practices made possible by language, are the primary concern.

The more formal, methodological approaches that comprise Discourse Analysis focus on the structure of spoken or written texts, and confine their study to those texts – often in terms of content analysis – leaving questions of context and how much can be inferred from the linguistic data to others (see van Dijk, 1997). One prominent approach deals with the role that metaphors play in social life, and highlights the frames of reference through which problems are understood; for example, ‘war’ versus ‘crime’ in the struggle against terrorism, or ‘choice’ in the debates about public services and reproductive rights (Lakoff and Johnson, 2003 [1980]).

Critical Discourse Analysis (CDA), exemplified in the work of Fairclough (2001), extends the range of interpretive concern beyond the structures of language to the social and political context. While beginning with an analysis of language texts, CDA also includes the processes of text production, distribution and consumption in its approach. Finally, CDA is concerned with the way in which sociocultural practice is comprised of discursive events. As such, CDA argues that linguistic and social resources are controlled institutionally and access to them is unequal.

While CDA extends the concern with language to the social, it perhaps does not go as far as more interpretive and less formal approaches to discourse analysis. Allied with the conception of discourse as performative, these approaches largely shun the idea of discourse analysis as a specific methodology, because they argue that all analysis...
necessitates an encounter with the discursive given the impossibility of apprehending an extra-discursive realm beyond language and other modes of REPRESENTATION (see Howarth, Norval and Stavarakakis, 2000). Here, although few of these authors would present their thought in these terms, Roland Barthes’ examination of mythologies, Jacques Derrida’s notion of DECONSTRUCTION and Michel Foucault’s account of GENEALOGY would all count as critical analyses of discourse, even if they could not be understood as Discourse Analysis. Nor is this broadly defined critical approach to discourse limited to questions of language or text (even if they are understood as social practices). As Rose (2007 [2001]) makes clear, discourse analysis is an important methodology for the study of visual culture (see VISUAL METHODS).

disease, diffusion of

An area of MEDICAL GEOGRAPHY that is concerned with mapping and modelling the spread of infectious diseases and their causative agents (e.g. viruses, bacteria and protozoa) over SPACE and through TIME. The approach is characterized by the application of QUANTITATIVE TECHNIQUES to decipher the spatial and temporal properties of EPIDEMIC waves in terms of their timing, intensity, rate and geographical corridors of spread (descriptive models), and to apply this understanding to the prediction of future disease distributions (predictive models). Particular concern with the topic stems from a need to intervene in the spread of epidemic waves (e.g. through the implementation of quarantine or vaccination) as part of public HEALTH policy.

Geographical interest in the spread of infectious diseases was stimulated by a broader disciplinary concern with spatial DIFFUSION that followed from the influential studies of Torsten Hägerstrand in the 1950s (see Haggett, 2000). Within the tradition of diffusion modelling initiated by Hägerstrand, geographers have sought to identify the nature of the diffusion processes by which infectious diseases are propagated spatially, and to incorporate elements of these processes into formal mathematical MODELS of epidemic transmission. Two basic types of spatial diffusion process have received particular attention in the literature. A contagious process describes the wave-like spread of a disease from its point of introduction to geographically proximal centres. Alternatively, a hierarchical process describes the spread of a disease through an ordered sequence of classes or places (e.g. an urban settlement hierarchy). Spatial diffusion processes of the contagious, hierarchical and related forms have been modelled for a wide variety of diseases in different historical and geographical settings; the classic studies of Pyle (1969) on cholera in the nineteenth-century USA and Cliff, Haggett, Ord and Versey (1981) on measles in twentieth-century Iceland are illustrative of the work undertaken.

Mathematical models of epidemic diffusion processes can be divided into two broad types. In time series models the past record of a disease in a regional system is used to model its future behaviour. In process-based models the person-to-person transmission of an infectious agent is simulated according to the parameters of the disease and the population at risk. Cliff, Haggett and Smallman-Raynor (1993, pp. 359–410) provide a review of the principal categories of model, along with a summary of their relative merits as tools for epidemic forecasting. The insights offered by such modelling approaches are increasingly being used in the monitoring and control of vaccine-preventable diseases, with the prospect of the construction of global early warning systems for the transmission of PANDEMIC events.

Disneyfication

A process through which a place becomes marketed primarily as a tourist destination, through standardized LANDSCAPE symbolization. The term derives from the Walt Disney theme parks that originated in California in 1955. Disneyland offered highly organized SPACE with themed areas, united by the central ‘Main Street’ (Avila, 2004). It celebrates order, cleanliness and predictability as part of the tourist-in-playground experience (Sorkin, 1992a; Avila, 2004). Sorkin (1992a, pp. 216–17) argues that Disney spaces celebrate travel and consumerism in a simulated experience and landscape that mimics reality, but is never quite real. The term ‘Disneyfication’ suggests a critique of this commodification of PLACE.

distance decay

The attenuation of a pattern or process with distance from a central point.
Its importance in the evolution of spatial patterns was enshrined in Tobler’s (1970) famous ‘first law of geography’: ‘everything is related to everything else but near things are more related than distant things’. Distance-decay relationships underpin much of the work on spatial structures undertaken within spatial analysis and spatial science, because the costs of spatial interaction are related to the distance travelled (cf. gravity model). Empirical studies have identified a range of distance-decay relationships in which the degree of attenuation with distance is much greater in some situations than others (see figure), in part because of the characteristics of the geometric configurations of the spatial structures within which they are set (Cliff, Martin and Ord, 1975–6).

**distance decay** Distance-decay curves and transformations (Taylor, 1971)

**division of labour** The separation of tasks within the labour process and their allocation to different groups of workers. Two forms are commonly identified:

1. **Social division of labour** – the division of workers between product sectors (e.g. ‘car workers’ or ‘textile workers’).
2. **Technical division of labour** – the division of the production process into tasks, and the specialization of workers in one or a small number of these (e.g. managers, supervisors and assembly workers).

The division of labour tends to be greater in more complex and industrialized societies and is a central component of the production systems of fordism. On the other hand, the putative emergence of post-fordism has been associated with more flexible forms of work organization and the limited re-integration of previously separated tasks (cf. flexible accumulation).

Altman, MacDonald and McDonald (2005).
Other applications of the concept of the division of labour include:

(3) Gender division of labour – in which specific jobs are assigned to men or women: in Western societies nurses tend to be women, and coalminers men. This extends beyond paid employment, so that unwaged DOMESTIC LABOUR is largely performed by women (see GENDER; PATRIARCHY).

(4) Cultural division of labour – according to the theory of internal colonialism (Hechter, 1975), regional minorities bear the same relationship to the majority as a colony does to the metropolitan power under COLONIALISM. The periphery supplies the core with raw materials and labour, forming a division of labour between the minority and majority cultures (see CORE-PERIPHERY MODEL).

(5) Ethnic division of labour – in colonized and other ethnically divided societies, employment is frequently stratified according to ETHNICITY.

(6) International division of labour – characteristically, less-developed countries produce raw materials and developed countries produce manufactured goods. More recently, a NEW INTERNATIONAL DIVISION OF LABOUR has involved the development by TRANSNATIONAL CORPORATIONS of production facilities in less-developed countries. Initially, such facilities concentrated on routine and lower-skill manufacturing tasks. Subsequently, technological advances and the availability of large numbers of higher-skill (but still relatively low paid) workers in poorer countries have seen a major growth in the outsourcing of business and professional services to countries such as India.

The cultural division of labour may be seen as a special instance of:

(7) Spatial division of labour – a concept developed by Massey (1984) involving the concentration of particular sectors and/or production tasks in specific geographical areas.

According to Sayer (1995), the significance of the division of labour in the organization of economic activity has been systematically underestimated. He argues that the complexities of modern industrial economies are such that they cannot feasibly be centrally planned, and nor can the social division of labour be abolished. For Sayer, this means that traditional Marxist approaches to geographical change (see MARXISM) must be rethought to recognize that the political challenges posed by the division of labour would not disappear with the transition to a post-capitalist society (see also Sayer and Walker, 1992).

domestic labour Work that is done in and around the home: activities such as housework, food preparation, childcare and the care of disabled, sick and ageing household and family members. Domestic labour is the focus of much feminist scholarship because women tend to do this work, regardless of whether or not they have part- or full-time paid employment. This has implications for the location, type and hours of many women’s paid employment, and is an important factor contributing to the persistence of women’s ghettoization in ‘female-dominated occupations’, and the disparity between men’s and women’s wages (Hanson and Pratt, 1995: see FEMINISM; FEMINIST GEOGRAPHIES). Whilst many women in industrialized countries do this ‘double shift’ of domestic labour and paid employment, some middle-class women hire other women – typically racialized, working-class women or migrants from the global South – to do this work for them (Momsen, 1999; Pratt, 2004). GENDER oppression is thus layered on to other forms of social and GEO POLITICAL domination. In some cases, domestic labour is then stretched over very great distances, as women caring for middle-class children in the global NORTH strive to mother their own children still residing in the global SOUTH, through daily or weekly emails and telephone calls.

Domestic labour is ambivalently valued in feminist analyses, viewed simultaneously as a burden and constraint, and as invaluable practices of care and social co-operation. Feminists have developed different strategies to remedy the unequal gender division of domestic labour. One strategy is to un-gender domestic labour, by striving towards equal contributions by men and women, as well as more collective options such as socialized childcare. A second, complementary, approach is to revalue domestic labour by demonstrating
its importance to the economy. Within marxism, domestic labour is seen as necessary to the social reproduction that supports and sustains economic production; periodically, marxist geographers have had to be reminded of this importance (Mitchell, Marston and Katz, 2004). Other attempts to bring domestic labour within the economy – to make it more visible and highlight its value – have included ‘wages for housework’ campaigns, and efforts to include questions about domestic labour on questionnaires related to national censuses. The latter allow the extent and worth of such labour to be measured and potentially figured into calculations of national economic activity, such as gross national product (Domosh and Seager, 2001, p. 45). Cameron and Gibson-Graham (2003) argue that the second set of strategies (which they characterize as ‘adding on’ and ‘counting in’) ‘fall short of generating a feminist politics of transformation’ (p. 151), because they seek to include domestic labour within existing ways of thinking about the economy, rather than using domestic labour as a vehicle for thinking about the economy differently. Rather than incorporating domestic labour into a broader conception of the capitalist economy, these authors urge that domestic labour be rethought within a diverse economy of market/non-market, paid/unpaid, capitalist/non-capitalist relations. England and Lawson (2005) caution that the category itself maintains troubling conceptual borders by reinforcing a distinction between domestic and other kinds of work.

domesticity The process by which plant or animal species are reshaped through the social and economic uses to which they are put by human societies in particular cultural and historical contexts. As this implies, human societies have altered the genetic composition of plants and animals by influencing their reproduction and life histories so as to make them better fitted to human needs and designs (see Clutton-Brock, 1999). In his theory of evolution, Darwin (1998 [1868]) called this process ‘artificial’ (as opposed to ‘natural’) selection and illustrated it with the example of pigeon-fanciers (see darwinism). Some domesticated species and organisms can become adapted to the point of dependency on human relations – for example, garden plants and companion animals or agricultural crops and livestock – and would have difficulty surviving outside of that domesticated context.

Domestication is strongly bound up with the centrality of cultivation to Western ideas of civilization and the advancement of human societies from the state of nature. Here, the process of domestication is understood as consequential not only in terms of altering the physiognomy of plants and animals, but also the sociocultural practices of what is taken to define human beings (Anderson, 1997). The historical realization of these ideas in the political and legal practices of colonialism finds echoes in those of the post-colonial present through the persistent imperatives of the scientific management and technological improvement in the efficiency and productivity of natural resources. In an era of biotechnology, this historical legacy informs new geopolitical investments in the meaning and practice of domestication. In forums such as the Food and Agriculture Organization and the World Trade Organization, for example, Western countries have asserted claims to intellectual property rights in biological resources on the basis of scientific interventions in what are presented as previously ‘natural’ materials (see patenting). By contrast, countries in the global south have sought to assert the claims of farmers and indigenous peoples to equivalent rights in recognition of their transformative ecological relations with plants and animals time-out-of-mind.

DOMINATION

up with CAPITALISM and PATRIARCHY (Gregson and Lowe, 1994). Feminist geographers have studied the GENDER, CLASS and racialized POWER relations of paid and unpaid domestic work, and the ways in which the transnational MIGRATION of domestic workers, particularly women, binds household to global economies and inequalities (including Pratt, 2004). A wide range of other geographical research has explored domestic technologies and rationalities, domestic interiors, embodied domestic practices and domestic MATERIAL CULTURES (for an overview, see Blunt and Dowling, 2006). Important themes include the ways in which domestic practices reproduce, recast and resist ideas about the home and/or family and the ways in which domesticity is closely bound up with MODERNITY, power and IDENTITY.

Geographies of domesticity also extend far beyond the household. As Amy Kaplan (2002) observes, the term ‘domestic’ has a double meaning, referring both to the SPACE of the NATION and to the space of the household. Both of these meanings are closely bound up with shifting ideas about the ‘foreign,’ and are imagined and materialized through a range of domestic politics and practices. Rather than view domesticity as confined to a PRIVATE SPHERE of influence, it is a crucial site of reproduction and resistance that is intimately bound up with the world beyond, as well as within, the household. Historical studies reveal the ways in which domesticity was explicitly and intimately tied to wider national and imperial politics through, for example, DISCOURSES and practices concerning maternity, CONSUMPTION and child-rearing (including Stoler, 2002). Other research has shown the importance of domesticity in anti-imperial nationalist politics, often focusing on the politicization of women within and beyond the home (including Legg, 2003).

Studies of domesticity in both historical and contemporary contexts usually focus on the material and symbolic importance of women. Whilst a wide range of research documents the oppression of women through domestic work and domestic VIOLENCE, other research explores domesticity as a site of potential creativity, power and resistance. Other researchers have begun to investigate the domestic lives of men and the relationships between domesticity and masculinity (see, e.g., Tosh, 1999).

domination The physical or cultural assertion of POWER over an individual, social group or TERRITORY. The term refers to the practice and manifestation of power relationships, especially in terms of the construction of territory and spaces as a means of control.

Domination was originally perceived in a classical GEOPOLITICAL sense of territorial control. In the late nineteenth and early twentieth centuries, geopolitical theories advocating the expansion of state BORDERS at the expense of ‘inferior’ cultures were the basis for the FRONTIER expansion of the USA and Russia, Germany’s desire for territory in eastern Europe, and the establishment of European empires. In this period, domination was viewed as the ability of a STATE to control territory – and hence its residents – on the basis of cultural superiority. In the COLD WAR period, domination was also seen as a matter of the power of states to define and attain their own self-interests.

However, critical scholarship began to define other forms of domination. The Marxist Antonio Gramsci (1971 [1929–35]) noted that the ideas of the ruling CLASS are mainly accepted by the whole of society, producing acquiescence in national projects of capital accumulation that benefit a few (cf. HEGEMONY). Edward Said’s (2003 [1978]) exposition of ORIENTALISM illustrated the cultural practices by which colonial powers created a sense of superiority over their subjects through literature and the arts. The practices of cultural domination have been addressed by geographers at a number of SCALES, from the construction of EMPIRE to the normative understanding of PLACES that exclude particular people, groups and behaviours (Cresswell, 1996).

Feminist and queer studies (see FEMINIST GEOGRAPHIES; QUEER THEORY) have emphasized the HETERNORMATIVE and PATRIARCHAL character of SPACES ranging from the HOUSEHOLD to the nation-state (Staeheli, Kofman and Peake, 2004). In addition, the racial domination of whites is gaining increasing attention (see WHITENESS). However, criticism remains that many human geography studies tend to ignore questions of RACE, GENDER and SEXUALITY (Staeheli, Kofman and Peake, 2004). Still, the emphasis placed upon cultural domination has been connected to the creation of material spaces of racial SEGREGATION in the city, hate CRIME activity in gay NEIGHBOURHOODS and patriarchal practices. In a separate vein of work, the role of the USA as hegemonic power has attracted the attention of geographers, especially its role in dominating the global political agenda and its massive military power.

Flint (2004); Staeheli, Kofman and Peake (2004).
**domino theory** A theory of geopolitics originally proposed by the USA in the 1950s, claiming that if one country joined or was forced to join the Soviet Union’s sphere of influence, then its neighbours would inevitably follow. The theory rested upon an analogy of toppling dominoes and was used to justify the military and political involvement of the USA in other countries, especially in South East Asia, in the 1950s and 1960s, but also in Central America in the 1990s (see also Cold war). O’Sullivan (1982) critiques the theory for ignoring the unique history and internal politics of different countries (the dominoes). CF

**dry farming** A set of farming techniques for crop cultivation without irrigation, used in areas with variable or little rainfall (Heathcote, 1983). Dry farming requires both water and soil conservation measures, such as mulching, frequent weeding and summer fallowing in alternate years. A long-established practice in the Near East, North Africa and north-west India, dry farming can only produce a narrow range of crops and low yields. These methods were instrumental in the extension of crop cultivation into the semi-arid areas of the Americas and Australia by European settlers in the nineteenth century. Dry farming is seeing a minor resurgence among followers of sustainable agriculture. JGU

**dual economy** An economy made up of two supposedly distinct parts: the modern economy and the pre-modern economy. The term was probably first used by Dutch economist J.H. Boeke, in his account of Indonesia as a dual society (Boeke, 1953). Boeke maintained that parts of Indonesian society had already become modern: some urban enterprises were organized according to recognizably scientific and capitalist principles, and were situated in neighbourhoods that seemed ‘Western’ to Boeke. Most of Indonesia, however, was ‘Eastern’ or pre-modern: life and work here were loosely organized and geared to the production of things for household consumption or local exchange.

Boeke’s work on Indonesia was meant to contribute to Public Policy debates. The question he raised was the classic mid-twentieth-century question of how to get from A to B, or from a traditional society to a modern society (see Modernization). As in many of these models, cultural change was thought to be driven by economic development. This was certainly the case in W. Arthur Lewis’ (1954) account of ‘economic development with unlimited supplies of labour’. Lewis argued that vast pools of unproductive rural labour could be decanted to the urban-industrial sector without affecting levels of food production. Scarce resources could then be channelled into the ‘commanding heights of the economy’, much as the Indian government tried to do in its Second and Third Five Year Plan periods (1956–66). Even better, urban real wage rates would not rise in the short run. Rural-urban migration served an equilibrating function, and helped to ensure that the modern economy would slowly take the place of the pre-modern economy.

In the 1960s and 1970s, the logic of this version of the dual economy model was turned upside down. Michael Lipton (1977) famously argued that most of the poverty of the Third World was in the countryside, along with most of the low-cost sources of economic advance. To neglect the rural sector in the name of an abstract model of economic modernity was inequitable and inefficient. It installed urban bias as public policy and stalled the process of human development. Other critics sympathized with some parts of Lipton’s critique — noting also the growth of urban slums and shanties – while challenging the dual economy model to which he still subscribed. Recent thinking has focused on the complicated ways in which ‘rur-urban households’ put together livelihood strategies across the town/country divide. Such thinking is focused on the economic costs of barriers to mobility, rather than on the presumed integrity of the urban or rural sectors (Ellis and Harris, 2004). Still other critics have gone further. Radical development theorists argued that the production of pre-capitalist spaces in an economy was a legacy of colonialism, rather than a state of original sin (see Dependency theory). In any case, the two sectors were linked to the advantage of the ‘modern’ sector. Finally, and perhaps most pertinently, recent work has emphasized that modernity is not a singular condition. There are many forms of modernity, all of which are structured by a high degree of path dependence. It is a fantasy to suppose that ‘Eastern’ parts of a dual economy can be made ‘Western’ in the sense of the mid-twentieth-century USA, and a fantastical abuse of public policy to push for this. SCO

Ecofeminism An umbrella term for a wide variety of environmental concerns and approaches that integrate diverse feminist and environmentalist perspectives. Ecofeminism is both theory and praxis, building on the intellectual foundations of ecological and feminist political movements where these intersect as, for example, in popular mobilizations in the name of peace and nuclear disarmament (Seagar, 1993), animal welfare (Gaard, 1993) or environmental justice (Shiva, 1988). There are different accounts of the origin of the term itself, but it is most frequently attributed to the 1980 work of the French author François D’Eaubonne.

The thematic connection linking diverse ecofeminist currents is the notion that women are closer to nature. This putative connection is woven into the mainstream intellectual, religious and social fabric of many cultures, and has been an important focus of feminist critique (see feminism). For several decades, feminists sought to distance the analysis of women’s position in society from any bodily or biological referent, labelling any such reference ‘essentialist’ and, thereby, unspeakable (see Fuss, 1989). As a consequence, ecofeminist concerns and arguments were cold-shouldered by the feminist academy for some years when they found their most powerful expression in works of the imagination as, for example, in the science fiction writing of Ursula le Guin or Marge Piercy.

While ecofeminism’s conservative tendencies to reduce the heterogeneity of women’s experience to the singular figure of Woman and the mutability of nature to an unchanging primordial Nature remain, since the late 1980s ecofeminist work has found new consonance with developments in feminist philosophy and social theory (see, e.g., Plumwood, 1993). These developments centre on concerns with (i) the materialism of social life and its connectedness beyond the human (see also biophilosophy) and (ii) the situatedness of knowledge production associated with the rise of feminist science studies. As Donna Haraway, one of the leading proponents of this latter project, has argued, ‘Ecofeminists have perhaps been the most insist on some version of the world (nature/body) as active subjects, not as resources to be mapped or appropriated in bourgeois, Marxist or masculinist projects’ (1991, p. 199).

Ecological fallacy A problem that may arise when inferring characteristics of individuals from aggregate data referring to a population of which they are part. It was first highlighted by Robinson (1950), who found correlations of 0.773 in a regression of the percentage of African-Americans in a state’s population against its percentage illiterate, but only 0.203 when using data on individuals from the same source. The fact that African-Americans were concentrated in states with high illiteracy rates did not necessarily mean that African-Americans had high illiteracy rates (hence the necessity not to confuse correlation with causality).

Alker (1969) identified six related fallacies:

- the ecological fallacy – assuming that relationships identified using aggregate data apply to the individuals concerned;
- the individualistic fallacy – assuming that the whole is no more than the sum of its parts (the inverse of the ecological fallacy);
- the cross-level fallacy – assuming that a relationship identified in one aggregation of a population applies to other aggregations (cf. modifiable areal unit problem);
- the universal fallacy – assuming that relationships identified among some individuals applies to all members of the population from which they have been selected, but not as a random sample;
- the selective fallacy – in which data from carefully chosen cases are used to prove a general point; and
- the cross-sectional fallacy – assuming that what is observed at one data applies to others as well.

All are problems of ecological inference, as is the more recently identified cross-time fallacy, whereby relationships that hold at one time are fallaciously assumed to hold at others as well.
EUROPE' Crosby (1986) described ecological imperialism as the environmental destruction of large tracts of the Earth by European colonization. Crosby chose to emphasize the imperial project largely in biological terms (rather than, say, military or economic) and the ‘encounters’ between hitherto largely separated regions of the earth now linked together by new systems of trade, production and forms of cultural interchange and settlement. As he put it, ‘the success of European imperialism has a biological and an ecological component’ (p. 7) (see ECOLOGY). Crosby traced the European settlement in the ‘Neo-Europes’ (North and South America and Australasia), a process in which their temperate agricultures thrived and local indigenous systems and ecosystems collapsed. The introduction of Old World pathogens decimated native populations (e.g. the Spanish devastated the indigenous populations of the Canaries by introducing pneumonia and dysentery). Smallpox decimated the Americas. In addition, Crosby charts the impact the introduction and dispersion of European ‘weeds’ and the transformative effects of, for example, the proliferation of new domesticated animals (see DOMESTICATION).

The term has been deployed in other more critical and expansive ways. In the activist world – and the so-called ‘movement of movements’ (see WORLD SOCIAL FORUM) – ecological IMPERIALISM is sometimes held to be ‘the imposition of a set of ecological values held by one individual or group onto another individual or group without their consent’ (Okonski, 2003). In this account the causes of eco-imperialism are multilateral agreements, foreign aid and the romanticization of the poor. A different, and more theorized and rigorous, account draws from Marxian theory, in which ecological imperialism is the product of the intersection of an expansionary capitalism on the one side and what Karl Marx called a ‘metabolic rift’ (Foster, 2000). The dispossession of peasants from the land, the creation of a pool of landless labourers and the concentration of the means of production (see PRIMITIVE ACCUMULATION) historically left a deep ecological footprint. Land was reduced to a level of being a ‘venal object’ and this whole process operated on a global (imperial) scale. Marx’s notion of a ‘metabolic rift’ was derived from his analysis of Liebig and other German chemists of the soil, and the fact that an expansionary capitalism shipped nutrients far away, to cities and the imperial centre. A body of work has attempted to draw connections between an expansionary world system, the transition from FEUDALISM to capitalism, the differing forms of EMPIRE (and rule) and the distribution of ecological costs (Grove, 2003). Ecological imperialism in this sense is quite different from Crosby’s interpretation, and turns on the recursive aspect of primitive accumulation as it takes hold of and transforms different natural systems. In the current moment, the global search for germ plasm by private pharmaceutical companies – and relatedly the commodification of plant breeding rights – would be an example of ecological imperialism in action (cf. BIOPROSPECTING). None of this is to suggest, however, that the ‘older’ forms of primitive accumulation – peasant dispossession and the ecological destruction that stems from it (e.g. the Three Gorges dam project in China) – are not still proceeding apace. Mw

ecological inference Drawing conclusions about individuals from data about the populations to which they belong, in the absence of any information about the individuals themselves. The data deployed almost invariably refer to population aggregates defined by territorially bounded areas, such as those used in the production of CENSUS data. In a classic case, analysts have wanted to know election turnout rates by different ethnic groups in the USA, but the only available information indicates the total turnout in each area and its population’s ethnic composition. Various QUANTITATIVE METHODS have been used to estimate separate turnout rates for each group from that information, but technical problems cast doubt on their validity. Recent developments offer possible solutions in certain circumstances, with the potential of providing more reliable estimates of unknown values. (See also ECOLOGICAL FALLACY; ENTROPY-MAXIMIZING MODELS; MICROSIMULATION.) RJ

ecology A science primarily concerned with the non-human world and, more specifically, with the complex relations between organisms and their environment. As such, ecology is considered something of a holistic and synthetic science, drawing on population and evolutionary biology, soil science, hydrology, earth systems, oceanography, chemistry, conservation biology and other sciences in attempting to understand how individual organisms and populations interact with other species and, more generally, how organisms
are linked to their biotic and abiotic environments. Some view ecology as the science of environment, although ecology may be distinguished from environmental science in its primary emphasis on understanding living organisms, not only at the individual, population and species levels, but in terms of identifiable communities of plant and animal species in relatively proximate interactions. The term ‘ecology’ is most often seen as a neologism coined by German biologist Ernst Haeckel, who first used it in 1866, in part inspired by Darwin’s *Origin of Species*. But the word draws directly on an older notion of ‘oeconomy’, which refers to management of the ‘household’ in a broad sense (Worster, 1994: see ECONOMY). This links the etymology of ecology and economics in intriguing ways, but also conveys something of the broad scope of ecological enquiry, encompassing the world of living things. In this sense, the lineage of ecology is much older and more diverse, drawing on the natural history of figures such as Gilbert White (1720–93) and Linnaeus (1707–78) (Worster, 1994), and linked by some to Aristotle’s writings on environmental changes in Greece. Significantly, modern ecology and GEOGRAPHY have been closely linked, not least in drawing on the early BIOGEOGRAPHY of Alexander von Humboldt. More generally, ties between ecology and geography have been forged and renewed based on shared concerns and perspectives, including the spatial organization and foundation(s) of biodiversity and how it is affected by human action, the implications of human action on the non-human world more generally, and the use of synthetic, relational and holistic reasoning to understand how ostensibly discrete entities are connected (not least in spatial terms).

Since the late nineteenth century, ecology in the Anglo-American world has been closely linked to environmental politics. During a first generation of ecology, exemplified by Stephen Forbes’s (1887) singular publication ‘The lake as a microcosm’, ecology was animated by concern with the implications of forestry, fisheries and agriculture (Schneider, 2000). In the post-Second World War period, this link between environmental politics and ENVIRONMENTALISM on the one hand and ecology on the other was consolidated through scientific enquiry into such matters as the ecological effects of radiation from nuclear technologies and the persistence of synthetic organic compounds in the environment (the latter is most famously associated with Rachel Carson and her signature work, *Silent spring*). Close association between environmentalism and ecology has continued, as was clearly evident in the way ecological enquiry was used to mediate the northern spotted owl controversy of the 1990s (Prudham, 2005). Not surprisingly, the close association of ecology and environmentalism has had a major impact on intellectual and scholarly work inside and around geography, helping to inspire the emergence of a distinct interwoven field of ENVIRONMENTAL HISTORY and HISTORICAL GEOGRAPHY preoccupied with the human origins and implications of environmental change, and drawing upon such changes as the basis of critique (see, e.g., Cronon, 1991; for a discussion linking environmental history and historical geography, see Williams, M., 1994a). POLITICAL ECOLOGY, as the name would suggest, has been similarly concerned with mobilizing ecological theories and methods in exploring the local and regional origins and implications of environmental degradation (however defined) in the context of uneven POWER relations.

During the middle of the twentieth century, particularly after the work of Frederic E. Clements, ecological research and theory generally emphasized predictability, stability, homeostasis and climax communities in the development of self-contained ECOSYSTEMS whose development, when unimpeded by human action, would tend towards increasing biological diversity. Clementsian ecology in particular stressed the recovery of ‘disturbed’ ecosystems from less to more diverse communities, culminating in highly stable climax ecosystems characteristic of particular REGIONS (Clements, 1936). Later, this was augmented by the development of an increasingly formal, abstract and often highly mathematical SYSTEMS ecology, emphasizing the modelling of populations, energy and material flows within ecosystems, and predicated on the assumption that discrete populations of organisms compete to fill exclusive ecological niches. Stability and homeostasis remained core principles of systems ecology.

Key concepts from Clementsian as well as systems ecology informed modernist RESOURCE MANAGEMENT paradigms. This includes the Lotka–Volterra equations used to model interconnected and predictable oscillations of predator and prey species in closed systems of mutual dependence, and the characteristic logistic growth curve underpinning maximum sustained yield management prescriptions in fisheries and FORESTRY. In each case, populations are seen to converge on stable carrying
capacities defined by limits on key resources (e.g. food) in closed systems. These are generalizations, in some sense crude, but they generally point to an ecology dominated by generalizable ideas about discrete, ontologically real ecosystems whose behaviour is predictable, and whose tendencies are towards increasing biological diversity and stability if left undisturbed by human action.

Yet if twentieth-century environmentalism and ecology have shared an affinity, ecology’s attempt to define and speak for a strictly non-human nature has raised some difficult issues that ecology has been, as yet, unable to resolve. These issues are in part invoked by the transition from Clementsian and systems ecology to the so-called ‘new ecology’ achieved by degree over approximately the past two decades. New ecology has numerous facets, but is generally characterized by an embrace of complexity, history and path dependence (see Complexity Theory); an appreciation of interconnected geographical scales in ecological relationships; a retreat from the broad law-like generalizations of systems ecology; and, critically, an embrace of change, not constancy, as the new normal (Botkin, 1990). Ecosystems in this paradigm are increasingly seen as open to the point at which defining them robustly becomes increasingly problematic. Moreover, disturbances from volcanic eruptions, fires, storms, pest outbreaks and the like are seen as endemic. Empirical studies of ecological succession following disturbance – for example, in the aftermath of the Mount St Helens eruption in Washington State, USA – also demonstrate that ‘recovery’ does not necessarily tend towards pre-disturbance communities, nor does the strict lineage of succession posited by Clementsian ecology strictly apply (Swanson, 1987). Rather, ‘recovery’ depends somewhat on initial conditions, including the legacy of pre-disturbance communities.

For these and other reasons, the new ecology is typically more agnostic about what communities of organisms may be characterized as ‘normal’ in any given location. Many implications follow from this, including a significantly diminished capacity for ecology to provide the baseline against which environmental degradation is defined. And with this, more overtly political ecologies become necessary, based for instance, on the increase or decrease in landscape functions of various kinds (e.g. fuelwood production, hydrological recharge). At the same time, new ecology is much less able to sharply and categorically delineate between natural dynamics and those influenced by anthropogenic processes because of the acceptance that change is just as endemic in nature as is stability (for discussion, see Demeritt, 1994a; Worster, 1994). This in turn has made ecology a much less reliable foundation for environmental policies that would strictly delineate nature and culture; for example, conventional wilderness-oriented parks and protected areas, aimed at biodiversity conservation (Zimmerer, 1994a). The new ecology has also more generally prompted considerable ontological soul searching among ecologists. And yet, as ecology has struggled to come to terms with complexity, context, path dependence, scale and the basis of inter-subjective knowledge claims about the non-human world, there remain strong parallels and linkages between ecology and geography, not least in embrace of the pervasiveness of hybrids that transgress formerly stable categories, be they ecosystem boundaries or nature–society dualisms (Zimmerer, 2000; Whatmore, 2002a).

ecometrics A term coined by Stephen Raudenbush (see Raudenbush and Sampson, 1999) to assess the nature of ecological settings, using the quantitative methods of multi-level (see multi-level modelling) and spatial models to exploit spatial dependence in order to improve the reliability and validity of measures of neighborhood social processes (cf. contextual effect; neighbourhood effect). Unlike traditional factorial ecology (see factor analysis), which uses aggregate, usually census, data to characterize places, ecometrics uses data on individuals plus systematic social observation as repeated measures of place characteristics. It is also concerned with how places change over time.

economic base theory A theory that explains urban and regional growth in terms of a division of employment into basic and non-basic sectors. The basic sector (B) comprises those industries that meet external or export demand, and the location and growth of this sector is viewed as a function of national and international forces. The non-basic sector (S) is locally oriented employment, servicing the total local population (P). The total population is a function of total employment (E) and the economic base relationships are as follows:
\[ E = S + B, \quad P = \alpha E, \quad S = \beta P. \]

The coefficients \( \alpha \) and \( \beta \) can be obtained by regression using observations for a sample of cities or for one city or region over time. Growth (or decline) in local population and employment is controlled by changes in the basic sector, and the impacts (multipliers) of such changes can be calculated from the economic base equations:

\[
E = (1 - \alpha \beta)^{-1} B, \\
P = \alpha (1 - \alpha \beta)^{-1} B, \\
S = \alpha \beta (1 - \alpha \beta)^{-1} B.
\]

A unit increase in \( B \) generates \( \alpha/(1 - \alpha \beta) \) units of additional local population.

Economic base theory is very simplistic in its assumptions, but because its data demands are simple it has been widely employed in regional economic analysis. It is used, for example, in activity allocation models and Lowry models. Correct identification of the basic sector is crucial, and location quotients are frequently used for this purpose. Either industries with high indices of specialization are defined as basic industries, or the quotient is used to define a proportion of employment in an industry as basic; so that, for example, one-third of employment in an industry with a quotient of 1.5 is designated as basic employment. A more sophisticated approach is to use input–output analysis to trace actual inter-industrial linkages, but this is very data-demanding and expensive.

The major limitations of economic base theory spring from its aggregative nature: the difficulties of sector definition; the dubious assumption that the aggregate multipliers will remain constant; and an inability to trace the impact of particular basic sector shifts, such as a rise in oil exports, on specific sectors of the local economy.

Glickman (1997).

economic geography  A sub-field of human geography concerned with describing and explaining the varied places and spaces where economic activities are carried out and circulate. The discipline was institutionalized in the late nineteenth century in both Western Europe and the USA, and remains one of the core sub-fields of Anglo-American geography. There have been repeated attempts to forge links with its seeming intellectual soul mate, economics, but none have held. Economic geography from the beginning was more empirically grounded, concerned with context and conceptually open-minded, and at the same time less abstract and less formally theoretical than economics. There were moments when the two became close, but mostly they held themselves apart at a distance (as they do now; cf. New Economic Geography). Further, unlike economists, economic geographers never settled on a single methodology, set of techniques, list of venerated luminaries, disciplinary problematic or definitive definition. Change has been incessant, the field continually reinventing itself. It makes for an exciting, dynamic, open subject, one that never looks back, and a frequent conduit for new ideas into the rest of human geography, but there is a nagging sense that before old promises are realized, new ones are made. Economic geography sometimes seems like Penelope’s shroud: spun during the day, and unravelled the same night.

Existing in embryonic form as commercial geography, the discipline was formally defined in Germany in 1882 by Götz. While commercial geography ‘chiefly served practical ends’, the purpose of economic geography was ‘the scientific task of dealing with the nature of world areas in their direct influence upon the production of commodities and the movement of goods’ (Götz, quoted in Sapper, 1931, p. 627). By the 1890s, economic geography courses appeared for the first time in US university calendars (Fellmann, 1986). The first Professor of Economic Geography in Britain was Lionel Lyde, appointed in 1903 at University College London. Five years later, the University of Edinburgh created a lectureship for George Chisholm, who was author of the first English-language economic geography text, Handbook of commercial geography (1889). Economic geography was up and running.

Chisholm’s book (published in 20 editions), and J. Russell Smith’s later American version, Industrial and commercial geography (1913), set out an initial disciplinary agenda and intellectual style that still resonates. The original colonial context of the two books no longer applies, but continuing to remain germane were their concern with empirical detail, their celebration of numbers, their predilection for geographical categorization made visible by the map, their tracing of relations among places through economic flows especially of the commodity, their emphasis on the geographical effects of technological change and their
suspicion of theory (although presumably no contemporary economic geographer would go as far as Chisholm ‘to wish . . . th[e] love of pure theory to the devil’; quoted in Wise, 1975, p. 2).

Chisholm’s and Smith’s emphasis was on the COMMODITY, though neither appreciated the conceptual richness of the concept, with geography coming second. The American geographer R.H. Whitbeck (1915–16, p. 197) argued that it should be the other way around: ‘the unit should be the country and not the commodity’. The consequence was an increasingly regional focus, at least in economic geography in the USA, where the REGION was defined as unique, and represented by using one typological scheme or another. Clarence Fielden Jones’ (1935) textbook Economic geography, for example, used an eight-fold typology.

Hartshorne’s (1939) The nature of geography later provided at least a splash of scholarly respectability to an IDEOGRAPHIC regionalism. But it did nothing to connect the discipline to the fundamental changes that were about to transform a number of social sciences, and even some HUMANITIES, especially in the USA, turning on the widespread use of scientific methods and PHILOSOPHY (and propelled by the Second World War and later the COLD WAR). Economic geography initially resisted that impulse, but by the mid-1950s it too joined in. The resulting QUANTITATIVE REVOLUTION profoundly altered the discipline, bringing the systematic application of scientific forms of theorizing and rigorous statistical techniques of description and analysis (Barnes, 2001).

The discipline over the period 1955–75, sometimes labelled SPATIAL SCIENCE, was defined by:

1. Formal THEORY and MODELS, many begged, borrowed and stolen from NEOCLASSICAL ECONOMICS (RATIONAL CHOICE THEORY, general and partial equilibrium, LOCATION THEORY), and physics (SPATIAL INTERACTION THEORY and later ENTROPY-MAXIMIZING MODELS) (Pooler, 1977).

2. QUANTITATIVE METHODS, which were initially taken off-the-peg from inferential statistics, but later designed in-house to meet the peculiar features of economic geographical data (cf. SPATIAL AUTOCORRELATION; Gould, 1969a).

3. The use of computers, at first very crude and limited, but within a decade performing hitherto unimaginable calculations for instrumental purposes.

4. A philosophical justification based on some form of Positivism, the idea that only scientific knowledge is authentic knowledge (see SCIENCE).

5. A focus on abstract SPATIALITIES and geometrically defined location (cf. LOCA TIONAL ANALYSIS, SPACE-ECONOMY). Consequently, the ECONOMY was conceived as an independent spatial object, with its own causative powers, morphological form and internal generative processes.

Regions remained part of the economic geographical lexicon, but conceived utterly differently: as explanatory, theoretical and instrumental, a spatial unit to achieve functional objectives (cf. REGIONAL SCIENCE). The consequence was that people like Clarence Fielden Jones (and his book) were no longer recognisable as part of the discipline. They were not in the same field, not on the same planet.

This often abstract, closed and narrowly conceived discipline did not last. It was out of synch with its own disciplinary history, and increasingly out of synch with its own historical moment (see RELEVANCE). RADICAL GEOGRAPHY emerged during the 1970s, propelling economic geography in a different direction. Harvey’s (1999 [1982]) classical Marxist theorizing of capitalist ACCUMULATION and CRISIS was important (see MARXISM), but even more so was Massey’s (1984) work on industrial RESTRUCTURING, which was philosophically underpinned by REALISM and culminated in the LOCALITY project that dominated British economic geography during the late 1980s (Cooke, 1989) (although disavowed by both Massey and Harvey). Across the Atlantic, a group of radical economic geographers in California carried out important empirical and theoretical work – not on cases of CAPITALISM’s decline (as in studies of DEINDUSTRIALIZATION in the UK), but on its successes, such as high-tech industries (Scott, 1988b; Saxenian, 1994). Merging British and American interests from the late 1980s produced discussions around the transformation of an old, disintegrating FORDISM into a new, emerging POST-FORDISM (Tickell and Peck, 1992). Heavily influenced theoretically by French REGULATION THEORY, which was more open-ended, and less abstract and deterministic than classical Marxism, the economy remained central, but it was softened by recognition of the social institutions, and even the culture, in which it was embedded.

CULTURE and ‘embeddedness’ became keywords of the ‘CULTURAL TURN’ entering
economic geography from the mid-1990s (Thrift and Olds, 1996). Often drawing upon post-structuralism, there was an attempt to rethink both the larger nature of the discipline – its empiricist epistemology, its entrenched masculinism, its economistic logic (Barnes, 1996; Gibson-Graham, 2006b [1996]) – as well as particular substantive topics that could benefit from the new conceptual armature, such as labour and work (McDowell, 1997a; see labour geography), financial and business services (Thrift, 2005b: see money and finance), consumption and retailing (Miller, Jackson, Holbrook, Rowlands and Thrift, 1998) and the firm (Schoenberger, 1997). Such a turn, its proponents argued, also allowed economic geographers to denaturalize the object of investigation, the economy. Rather than treating the economy as ‘out there’, as a single inviolable object, it had to be conceived as a cultural product, fragile, performed and capable of realization in a variety of forms. In this conception, the line between culture and economy is not just hard to see, but is no longer there (see also cultural economy).

The ‘cultural turn’ is far from dominant, however, and already criticisms have mounted, and new alternatives or versions of old alternatives proposed. In truth, there is still no received view, orthodoxy or standard paradigm within economic geography. The current discipline is like a palimpsest, with past versions of the discipline still partially visible, not completely erased and continuing to contribute to the discipline’s present form. While there is no single leading approach, several areas of the discipline are marked by energetic research and debate:

(1) Discussion of methods is one (Tickell, Sheppard, Peck and Barnes, 2007). In the beginning economic geography was heavily indebted to empiricism (and still is), assiduously collecting numbers and statistics. Even during economic geography’s least numerate period, regionalism, Hartshorne (1959, p. 161) could claim that ‘objectivity . . . can best be accomplished . . . by quantitative measurements’. That was taken to an extreme during the quantitative revolution, but as that movement broke up during the 1970s it facilitated the proliferation of new qualitative methods and techniques, including intensive case-study research (Sayer and Morgan, 1985), in-depth interviews, oral histories (Schoenberger, 1996), ethnographies, participant observation, discourse analysis (Barnes, 1996) and action research (Gibson-Graham, 2006b [1996]). It is an approach to methods in which nothing is proscribed and everything is permitted. The upside is diversity and rapid change – most of the methodological techniques listed would have been viewed as beyond the pale, or at best, suspiciously avant-garde, even in the mid-1980s. The downside, though, is a preoccupation with the instant of disclosure rather than the slower processes of substantiation and extension (Martin and Sunley, 2001).

(2) Hand-in-hand with permissive methodology has gone permissive theory. Thrift and Olds (1996, p. 313) speak of a ‘polycentric’ economic geography consisting of a ‘set of narrative communities’ that ‘celebrate a qualitative multiplicity of “economic” times and spaces’. Those communities include an older mathematical modelling tradition, sometimes refurbished for the new economic times and spaces (e.g., Webber and Rigby, 1996) (but often not); varieties of political economy, loosely grouped around Marxism, and frequently focused on the state (most recently, its role in neo-liberalism: Peck, 2008); various stripes of feminism that sometimes intersect with political economy, and often turning on bodies of both men and women (McDowell, 1997a); a range of institutional approaches linked to economic anthropology and sociology (Polyanyi’s and Granovetter’s works are especially important) emphasizing embeddedness, networks and social capital (Saxenian, 1994); and selective theories drawn from science studies (particularly the work of Bruno Latour and Donna Haraway), used to understand the brute materialities of economic geographical activities, from the use of machines to the lurching movement of primary resources along the commodity chain (Cook, 2004). The absence of a single approach is liberating (no authority to which to kow-tow), but slightly disconcerting (the discipline continually starts anew with a clean slate).

(3) Both permissive theory and methods have been used to understand an issue increasingly preoccupying economic geography from the late 1980s, globalization, and forming a body of research as energetic as its focus of study. Globalization was made for economic geographical study. And in the beginning it was economic geography. Although they did not use the term, Chisholm and Smith were students of globalization. That focus was lost, however, as economic geography became the study of only Western industrial economies, and the rest of the world was parcelled up and given over to either regional geography or development.
GEOGRAPHY. Processes beginning from the 1970s, such as the emergence of a new international division of labour, the increasing hegemony of multinational corporations, the growth of international financial capital, and new forms of communication and long-distance transportation, showed economic geographers that they needed to deal with whole world. Further, under globalization the old intellectual division of labour in geography was not just redundant but obstructive. Dicken’s (1988) work on the geography of multinational corporations (now in its fourth edition) was one of the first to make this point. But he made another, just as important – that globalization was not a seamless process, eradicating geographical difference. Globalization represented not ‘the end of geography’, as economists portrayed it (O’Brien, 1992b, p. 3), but another form of its continuing importance. Geographical differentiations were the very preconditions for globalization’s possibility and achievement. Dicken and a former student, Yeung (2002), sharpened the point for firms, but similar conclusions were reached for the study of global commodity chains (Hughes and Reimer, 2004), international finance, world-wide mega-project property development (Olds, 2001), and the international migratory circuit of professional elites looking for elite jobs.

Finally, and perhaps surprisingly, primary resources and nature have become the focus of an animated disciplinary discussion. For a long period the topic was a backwater, and was almost lost altogether under spatial science. The simplifying assumptions required for spatial modelling meant that the uneven and lumpy nature of resources were treated as complicating factors, the analysis of which was promised but indefinitely postponed. Harvey (1974a) made a powerful case for considering nature along with the economy, but this was not nature ‘red-in-claw’ but social-nature, ‘the production of nature’, as Smith (2008 [1984]) put it. The production of nature did not mean creating something where before there was nothing. Nature pre-existed, but how it was exploited, used, thought about and represented once market capitalism arrived was utterly altered. The original Marxist approach emphasized the centrality of social relations in constituting the economic resource, and in doing so joined discussions with political ecology. In a classic paper, Watts (1994b) brilliantly showed how social relations in Nigeria made the natural resource of oil neither natural nor a resource; instead, it created mal-development, social discord and political mayhem (see also political capitalism). Since then, discussions of nature and resources have centred around two axes. One turns on hybridity, a notion drawn from science studies and extending what counts as social relations, and connoting the inseparability, their mixing and blending, of nature and the social – for example, Swyngedouw’s (1999) work on the political economy of water in Spain, and Morgan, Marsden and Murdoch’s (2006) on food. The other turns on the influence of discursive and regulatory regimes, particularly neo-liberalism, in defining nature and resources – for example, Bakker’s (2003) work on water, and the edited collection by Heynen, McCarthy, Prudham and Robbins (2007).

Economic geography is a discipline that is intellectually open, eclectic, pluralist, possibly chaotic and anarchic, and subject to temporary whims and fancies. Inconstancy is the only constant, inconsistency the only consistency. Over the past two decades the boundaries between economic geography and other sub-fields have become increasingly muddied and indistinct, as the very idea of a separate discipline, and a separate empirical object of study, has been contested (as reflected in the new textbooks for the discipline; e.g., Coe, Kelly and Yeung, 2007). Almost anything can now be fodder for its enquiry. Critics from outside have complained of a hopeless ‘fuzziness’ and slapdash approach (Markusen, 1999), while even inside there have been grumblings of a lack of rigour, focus and policy relevance (Martin, 2001b). The unusual challenge for the discipline will be less breaking new ground, which it seems to do on a daily basis, than holding its existing ground. TB

Economic growth A sustained increase in the production of goods and services, usually measured at the national level as the change in the gross domestic product (GDP) of a country’s economy. Economic growth is, at the same time, one of the most fundamental and perplexing issues in economic theory. There are still no conclusive answers to the questions of what causes economic growth and to what extent it can be sustained, which have been hotly debated since the time of Adam Smith and Thomas Malthus. Smith believed that the
ultimate engine of growth was the DIVISION OF LABOUR, the increasing elaboration of which drives productivity, which in turn determines growth (or the ‘size of the market’). Larger MARKETS would sustain higher rates of growth, and therefore growth would continue indefinitely. Malthus, for his part, was much more pessimistic. He argued that the human population would expand geometrically, while the supply of land (and therefore FOOD) could only grow slowly, resulting not only in a slowing rate of growth, but in catastrophic vulnerability to POVERTY and FAMINE (see MALTHUSIAN MODEL). Karl Marx also identified limits to the long-run rate of growth, caused in his analysis by the tendency of the rate of profit to fall and rising class conflict (see MARXIAN ECONOMICS). For Marx, economic growth would also be inherently unstable, following boom and bust cycles, along with periodic (and gradually increasing) bouts of unemployment (his ‘reserve army’ of labour). While Marx may have over-estimated CAPITALISM’s inherent tendency to system failure, his forecast of significant fluctuation in rates of growth, combined with spatially UNEVEN DEVELOPMENT, has been borne out by the historical record (see Blustone and Harrison, 2001; Duménil and Lévy, 2004).

‘Growth is the pivot on which INDUSTRIAL GEOGRAPHY turns’, Storper and Walker (1989, p. 36) have argued, ‘and change is the only constant in a world of persistent disequilibrium generated by the very nature of capitalist development’. There is no evidence of sustained convergence towards an equilibrium or natural rate of growth; indeed, there is a growing awareness that there are incipient, if not urgent, social and environmental limits to growth. But the search for the ultimate economic causes of growth continues. Often, it appears that the simple fact of growth is taken as a sign of causality. So, during the 1980s, the relatively strong performance of the German and Japanese economies prompted widespread debate around the essence of these apparently superior models of capitalism (see Albert, 1993). During the 1990s, when economic growth in both these economies faltered and American growth surged, this was held up as a validation of the brand of market-driven, technology-intensive growth found in the USA (Friedman, 2000 [1999]), the generic form of which is often described as NEO-LIBERALISM.

The late 1990s also witnessed the emergence of ‘new growth theory’, developed by economists Robert Lucas and Paul Romer, which posits that the ultimate causes of growth are endogenous (i.e. internal), the rate of growth being a function of the aggregate stock of CAPITAL (both human and physical), together with the degree of technological sophistication of the ECONOMY (e.g. the rate of investment in research and development). The policy implications of this model, which include accelerating the long-term rate of investment in technology and skills, have been explored by Bluestone and Harrison (2001). Here, they draw unfavourable contrasts with the prevailing ideology of neo-liberal growth, which favours short-term measures of market performance and an ethos of governmental deregulation.

Evidently, the search for the ultimate causes of growth continues, and with some urgency. Since the 1970s, growth rates across many of the advanced industrial nations have declined markedly, compared to the so-called ‘Golden Age’ of FORDISM, while the experience of less-developed countries (with the notable exceptions of India and China) has been decidedly uneven. This has led some to conclude that the ‘Golden Age’ of high growth has given way to a ‘Leaden Age’ of generally slower, and less sustainable, economic growth.

**ECONOMIC INTEGRATION** A term often coupled with GLOBALIZATION, and typically associated with claims about the virtues of free trade and unregulated capital MARKETS. If one searches for ‘economic integration’ on the website of the INTERNATIONAL MONETARY FUND (IMF), for example, some 3,350 documents appear – the bulk of which are concerned with defining the enabling conditions for expanding TRADE and CAPITAL flows, and documenting their beneficial effects. Such claims have been subject to intense contestation, exemplified most dramatically by the protests that erupted in Seattle in November 1999 at the time of the WORLD TRADE ORGANIZATION (WTO) ministerial meeting (see ANTI-GLOBALIZATION).

Some scholars question the extent and novelty of contemporary global economic integration, thereby casting doubt on efforts to portray it as an inexorable linear process. In the mid-1990s, for example, Hirst and Thompson (1996) observed that the international economy was actually less open and integrated than in the early years of the
twentieth century under the Gold Standard regime. They also pointed to the concentration of trade, investment and capital flows among Europe, Japan and North America. Since then, China has emerged as a major site of trade and investment flows, as well as the single largest holder of US debt.

Burgeoning US debt underscores the structural asymmetries that have propelled the liberalization of financial markets since the 1970s. A widely held view is that the collapse of the Bretton Woods system of international monetary and financial arrangements in 1971 represented a defeat for a weakened US capitalism, unleashing market forces that quickly gained ascendance over nation-state power (see Money and Finance). New information technologies and a ‘space of flows’ also figure prominently in this account of intensified economic integration (e.g. Castells, 1996a).

In a revisionist analysis of the shift to what he calls the Dollar–Wall Street regime, Peter Gowan maintains that the liberation of international financial markets was part of a deliberate strategy by the Nixon administration, ‘based on the idea that doing so would liberate the American state from succumbing to its economic weaknesses and would strengthen the power of the American state’ (Gowan, 1999, p. 23; italics in original). Cutting the link between the dollar and gold in 1971 meant that the USA could force revaluation on other states through its own policy for the dollar. In a second key set of moves, closely linked to the OPEC oil-price rise, the USA insisted that petrodollars be recycled through the private banking system and devised a set of incentives for commercial banks to lend to governments in the South. These included the abolition of capital controls, scrapping the ceiling on bank loans to a single borrower and repositioning the IMF to structure bail-out arrangements that shifted the risk of such loans to the populations of borrowing countries. While ensuring the banks would not lose, these arrangements have also meant that financial crises in the South provoked capital flight of private wealth-holders that ended up strengthening Wall Street (see Neoliberalism). While the banks and Wall Street benefited in the period after 1973, the continued liberalization of the financial markets came screeching to a halt in 2008 with the collapse of over-extended US investment banks and insurance houses, and the crippling of a global financial system made excessively vulnerable by a massive housing bubble driven by excessively leveraged banks deploying risky financial instruments (credit default swaps, for example) in a fiscal environment characterized by corruption, fraud and virtually non-existent regulation and oversight.

Neo-liberal forms of economic integration emerge from this analysis not as a set of inexorable technological and market forces increasingly divorced from state-political controls, but as integrally linked with what Harvey (2003b) calls ‘the new Imperialism’. Such understandings are crucial in a post-9/11 world in which economic integration and military force are becoming closely intertwined. GHa

economies of scale  The cost advantages gained by large-scale production, as the average cost of production falls with increasing output. Total production costs usually increase less than proportionately with output, up to a point where diseconomies of scale (cost disadvantages) set in.

Economies of scale generally arise from conditions internal to the operation of the plant in question. Some important internal sources of scale economies are: (a) indivisibilities, where plant is built to a certain capacity below which the average cost of production will be higher than at full capacity, and the plant cannot be divided up into smaller units working with the same efficiency as the larger one; (b) specialization and division of labour associated with expansion of scale, which can increase efficiency and hence lower costs; and (c) overhead processes, such as the design of a product, which must be undertaken and paid for irrespective of scale, so that the larger the output, the lower is the overhead cost per unit. Certain external economies may also be associated with expansion of scale of output; for example, if the growth of an entire industry reduces costs in each individual firm.

The existence of economies of scale encourages the expansion of productive capacity up to the point at which diseconomies eventually pull the cost of the additional (marginal) unit above the price that it will fetch. In some modern industry, it may be that this point is reached only at a very high volume of output, so that average cost continues to fall with rising output well beyond the level at which diseconomies might be expected to arise. However, in other activities a trend towards more flexible and differentiated production may lead to diseconomies at relatively small scale of output. (See also Economies of Scope.) DMS

ECONOMIES OF SCALE
economies of scope  The cost advantages that may arise when performing two or more activities together within a single firm rather than performing them separately. When economies of scope exist, firms have an incentive to internalize (i.e. perform in-house) the production of goods or services that otherwise would be acquired through transactions with external suppliers (see TRANSACTIONAL ANALYSIS). This incentive is normally expressed in terms of reductions in production costs as result of internalization (see TRANSACTION COSTS). Hence, economies of scope may arise where the goods or services in question share inputs to their production (e.g. by using excess capacity in power generation or indivisible machinery), are related to one another through INPUT–OUTPUT relations (one good being an input to the production of the other good), draw upon common technical or manual skills for their production, or can be most efficiently produced at roughly the same scale of output. This concept, when combined with the idea of ECONOMIES OF SCALE, provides an understanding of the forces that determine firm size and the nature of inter-firm relations in localized clusters of producers (Scott, 1988c). (See also PRODUCTION COMPLEX.)

economy  Economy is practice and object. As human practice, Aristotle defined oikos as operating the household (on patriarchal principles) to meet daily needs. Over time, as the meaning of economy migrated from the domestic to the public sphere within POLITICAL ECONOMY, it came to mean ‘seeking a desired end with the least possible expenditure of means’. As object, it refers to the hypothesis that practices of economy, now in the public domain, can be separated from the remainder of societal endeavour: as the economy. Economy has become central to social discourse as a result of this separation: human practices are thought of as reducible to means/ends rationality, and the (capitalist) economy is thought of as central to human well-being.

The genealogy of this separation of economy from related societal and biophysical processes is not yet clear. The question of how to organize society on secular principles, as a substitute for (Christian) religious mores, was a preoccupation of the ENLIGHTENMENT in France and Scotland. French Physiocrats constructed the first model of an economy as a self-sustaining entity. In 1758, François Quesnay built a tableau économique, forerunner of Marx’s theory of the circulation of capital and of post-1945 INPUT–OUTPUT MODELS, depicting the flow of net product from its presumed agricultural source, via landlords, ‘unproductive’ industrialists, and back to agriculture. British political economists concerned themselves with the benefits of organizing society around economy. It was held that the state could not rein in human passions, implying that the key was harnessing self-interest for this purpose. Avarice became constructed as a beneficial and mild interest rather than a passion, capable of taming other passions deleterious to society. Adam Smith solved the puzzle of how self-interest could create a society beneficial to all. He reduced self-interest to economic calculation, and articulated the principle of the invisible hand, whereby market competition would translate individual self-interested practices of economy into mutual benefit. Smith’s argument was geographical: the invisible hand and free trade would benefit Britain. These justifications gradually transformed into the abstract argument that self-interested practices of economy were universal, and generally socially beneficial.

Seventeenth- and eighteenth-century political economy focused on the relationship between economic processes and the national polity. Karl Polanyi (1944) argues that the economy was disembedded from society during Britain’s ‘Great Transformation’ to liberal CAPITALISM in the early nineteenth century, and increasingly, the economy was placed in a national frame. By 1841 Friedrich List, influenced by American economic policy, was proposing protectionist policies for the German national economy, facing the debilitating consequences of free trade with Britain.

After the 1890s, European and then American economists completed a marginalist, subsequently neo-classical, revolution reinforcing the principle of the invisible hand. Assuming a world of autonomous self-interested individuals of equal political power engaged in perfect competition, NEO-CLASSICAL ECONOMICS created a level playing field, on which equilibrium market prices would track the marginal utility of each COMMODITY; ensure that capitalists, landlords and workers are fairly paid (reflecting their marginal contribution to production); and maximize social utility, in a self-regulating market. It was also extended as a normative principle to broad areas of social life. RATIONAL CHOICE THEORY, the broadly influential idea that social structures and dynamics are the result of the rational economic choices of autonomous self-interested individuals, essentially grounds all social processes in practices of economy – and equates such actions with
capitalist markets. This vision of a harmonious self-regulating capitalist economy, grounded in self-interested practices of economy, and governed by rules of perfect competition, came to dominate social thought.

After 1945, as the formal end of COLONIALISM created a world largely divided up into autonomous NATION-STATES, each with acknowledged SOVEREIGNTY over their economies (controlling BORDERS, managing economic activities within the border), the idea of the national economy became commonplace. Indeed, much of the statistical knowledge produced about the economic aspects of society appears in reams of national statistics, produced using universally agreed practices of measurement (such as the Gross National Product; grounded in mainstream Anglophone economic theory), and collected and published by supra-national agencies. Timothy Mitchell (2002d) dates ‘the making of the economy’ to this POST-COLONIAL era; this is certainly when the discourse globalized.

ECOLOGICAL ECONOMY has at times aligned itself with such arguments – for example, during the 1960s – but even then serious reservations were expressed about the adequacy of this discourse. Earlier eras of COMMERCIAL GEOGRAPHY and REGIONAL GEOGRAPHY created an awareness of different, non-capitalist and non-individualist practices of economy in different places, that are perfectly adequate to the social and biophysical context in which they operate. For example, slash and burn and SHIFTING CULTIVATION remain highly functional for subsistence-based societies in delicate ecological environments (see SUBSISTENCE AGRICULTURE), now being destroyed by the clear-cutting of forest ecosystems to undertake cash-crop monoculture.

SPATIAL SCIENCE offered a nascent critique of capitalism’s self-sufficiency and social optimality, even under the extreme assumptions presupposed by neo-classical economics. It was shown that while neo-classical theory works well on the head of a pin, it breaks down in the real world of a geographically extensive SPACE ECONOMY. Perfect competition turns into monopolistic competition, the level playing field disappears and prices no longer approximate marginal utilities.

Marxian political economy, gaining popularity in economic geography during the 1970s and 1980s, offered much deeper criticisms: that CAPITALISM entails exploitation of labour and NATURE, generates social and political conflict and UNEVEN DEVELOPMENT, and is incapable of resolving these problems internally (see MARXISM). The space economy poses difficulties and complexities for Marxist theory too, but these only exacerbate capitalism’s internal contradictions. Capitalism thus cannot be disembedded from its non-economic context, as it depends on state intervention, biophysical processes with their own logic, social and legal norms, and CIVIL SOCIETY for its own reproduction (see also CULTURAL ECOLOGY). POST-STRUCTURALISM has pushed economic geography away from analyses that begin with even political economic processes, towards a view in which these are co-implicated with cultural, gendered and biophysical processes, and non-capitalist economic practices.

Geographical economy is inseparable from and constituted through societal and biophysical processes, and is variegated rather than simply capitalist. There is no single economy applicable to all places, with advanced capitalism constituting a ubiquitous best practice for all, but room for geographically differentiated possibilities and imaginaries.

ecosystem The concept of the ecosystem was proposed by the British ecologist A.G. Tansley in 1935, to describe the interaction of living things and their non-living surroundings, with which they interact. Tansley’s paper attacked the notion that the plant community was an ‘organic unity’, and vegetation succession a process of development to a ‘climax’ state (Sheail, 1987). Tansley suggested that CLIMATE, soils, plants and ANIMALS interacted together as parts of a SYSTEM, nested within a host of other physical systems (Sheail, 1995).

The ecosystem concept allowed a reductionist approach to the analysis of forests, fields, WETLANDS and other environments in terms of flows of energy and matter. It allowed metaphors from engineering, cybernetics and control theory to be applied to such environments, such as system, feedback, equilibrium, balance and control. Ecosystems are not dimensionally defined: they can be defined at any SCALE from pond, to ocean or biosphere. Classic studies, such as those of Odum on the energetics of Silver Springs in Florida (in 1956), involved small naturally bounded systems. Much of the claim of ECOLOGY as an experimental SCIENCE can be traced back to the power of the ecosystem approach.

The ecosystem, and the wider science of ecology, provided a framework for the analysis
and management of human impacts on non-human nature. In the mid-twentieth century, ecological ‘managerialism’ underpinned the expansion of global policy ideas about issues such as overgrazing, DESERIFICATION, deforestation and the problem of ‘fragile environments’. Ecologists sought to apply the ‘lessons’ of their interdisciplinary science to DEVELOPMENT; for example, in Ecological principles for economic development (Dasmann, Milton and Freeman, 1973). The ecosystem as a frame for understanding human impacts on the biosphere was fundamental to the ENVIRONMENTAL MOVEMENT of the 1970s and 1980s (at that time, often called the ‘ecology movement’) and to the expansion of CONSERVATION.

The ecosystem concept has had a significant impact on GEOGRAPHY, first in describing vegetation patterns on global (biome) or local scales, and second as a framework for analysing the interaction of SOCIETY and nature. Organism and ecosystem were discussed by David Stoddart (1967) in Chorley and Haggett’s Models in geography, both for their utility in explaining how the world worked and also as indicators of the value of the SYSTEMS approach and GENERAL SYSTEMS THEORY as a ‘unifying methodology’ for geography.

Despite the explosion of interest by human geographers in all aspects of the social construction of nature, the ecosystem continues to be central to natural scientific explanations of processes and patterns in the living environment, and human interactions with them. Moreover, recent ecological work on ecosystem disturbance and resilience has maintained interest in the ecosystem as a holistic frame for understanding human impacts on non-human nature.

**ecumene** A term used to mean ‘inhabited world’ or ‘dwelling place’. It generally refers to the historical process and cultural forms of human settlement, and to those parts of the Earth where people have made their permanent home, and to the economic activities that support that permanent occupation and use of land. It derives from the Greek oecumene, which referred specifically to the civilized world as it was known to the ancient Greeks (and, later, Romans) and centred on the Mediterranean (see CIVILIZATION). In some historiographies of GEOGRAPHY, ‘ecumene’ is presented as the unifying concept and distinctive concern of the discipline (James, 1972; see also GEOGRAPHY, HISTORY OF). In practice, it was in most active use by cultural geographers in the nineteenth and early twentieth centuries, along with the allied scholars in anthropology and archaeology, who were then concerned with the imperatives and distribution of human settlement (see CULTURAL GEOGRAPHY).

Ecumene was adopted as the title of a new journal launched in 1991 that sought to showcase the work of the ‘new cultural geography’ and the fields of study with which it was in conversation. That this journal was re-launched in 2005 under the more straightforward title Cultural Geography is perhaps indicative of a declining intellectual purchase and resonance of ‘ecumene’ at the start of the twenty-first century.

Ecumene; James (1972).

**edge city** An urban form in the USA, identified by Garreau (1991) and addressed by others (e.g. Beauregard, 1995). An edge city contains the industry, commerce and residences of traditional cities, but in less compact form (see EXOPOLIS; SPRAWL). Edge cities are new (largely emerging post-1970) and contain high levels of office and retail space. They have also become generally perceived as places in themselves, or ‘new downtowns’, on the edge of urban areas (e.g. Tyson’s Corner, Virginia). According to Garreau, these are not only ‘edge cities’ because of their peripheral location, but also because they are major centres of innovation.

**education** Studies of the geography of education focus on spatial variations in the provision, take-up, quality of and outputs from educational resources. Many of those resources are provided in facilities at fixed locations, so the provision of, for example, play-centres for pre-school children may involve differential ACCESSIBILITY, with implications for SOCIAL JUSTICE. The majority of facilities are PUBLIC GOODS in most countries, so their spatial allocation is a political process, as is public expenditure on education (cf. POSITIVE DISCRIMINATION).

Spatial variations in educational outputs are related not only to the quality of the facilities and institutions’ learning systems, but also to their social milieux. Students’ aspirations and performance reflect not only their innate abilities and home situations and the quality of
the school they attend, but also the characteristics of their school and neighbourhood peers. Strong \textit{neighbourhood effects} operate (Wöllmann, 2001: see also \textit{contextual effect}; \textit{multi-level modelling}). Their existence was the basis for challenges to the ‘separate but equal’ schooling systems once operated in many US states, whereby African-Americans and whites were allocated to separate schools: after the classic \textit{Brown v Board of Education of Topeka} Supreme Court decision in 1954, many school districts were required to integrate their schools to remove the unequal treatment suffered by the former group (Johnston, 1984). A commonly deployed strategy to achieve this was ‘bussing’, whereby students were transported from segregated neighbourhoods to mixed schools: this was increasingly countered by whites who either sent their children to private schools or moved to suburban school districts where housing was too expensive for most African-Americans (‘white flight’). Similar patterns have been observed regarding school choice in English cities (Johnston, Burgess, Wilson and Harris, 2006).

With the adoption of neo-liberalism in many countries, although education remains a public good, parental and student choice is promoted – as against the territorially structured school catchment areas that characterized earlier eras, when the composition of a school, and thus the contextual effects operating therein, reflected the neighbourhoods that it served. To facilitate this choice, information on schools – such as the performance of their students in public examinations and their truancy rates – are published, leading to the creation of school ‘league tables’.

Studies of \textit{geographical education} focus on the provision and nature of instruction in the discipline in schools and universities. Special interest groups – including \textit{geographical societies} such as the Geographical Association in the UK – lobby relevant authorities to ensure, for example, that \textit{geography} is in the school curriculum and that departments offer degrees in the discipline at universities, with varying success across countries. Leading \textit{geographical societies} – such as the Association of American Geographers and the Royal Geographical Society/Institute of British Geographers – include specialty groups whose purpose is to promote pedagogy, as do journals such as the \textit{Journal of Geography in Higher Education}.

Within universities, there is a growing trend of regularly assessing their performance – notably at research (as with the UK’s Research Assessment Exercise, which grades every university department every five years on average: Johnston, 1994, 2006) – and then allocating funds according to the results, which has the consequence of concentrating research in selected institutions only.

\textbf{egalitarianism} The view that all people are of equal fundamental moral or social worth, and should be treated as such. Egalitarianism can take a number of forms related to different types of \textit{equality}: equality of opportunity, equality of outcome, equality of wealth or power, equality of respect, equality before the law or equality before God. Egalitarianism implicitly informs much research on the geographies of inequality, including those associated with differences of \textit{gender}, \textit{class}, \textit{ethnicity}, \textit{sexuality}, age, corporeality and nationality (cf. \textit{nationalism}). The mitigation of \textit{spatial inequality} has been an important normative concern for geographical scholarship since the early 1970s (Harvey, 1973).

Lee and Smith (2004).

\textbf{electoral geography} The study of geographical aspects of the organization, conduct and results of elections. Pioneering studies were conducted early in the twentieth century, but most of the literature – produced by a small number of specialists – dates from the 1960s on.

Because voting in national and local elections is almost invariably place-bound (i.e. people have to cast their vote in a specified area, usually that containing their home) and the results are published for those places, a great deal of data that can be subject to geographical (i.e. spatial) analysis is created. Merely mapping election outcomes suggests that geography is ‘epiphenomenal’, however: that there is nothing inherently geographical about the processes producing the outcome, which just happens to be produced and displayable in spatial form. For geographers such as Agnew (1987a) and Cox (1969), however, the decision-making processes underpinning those mapped patterns are inherently geographical. The socialization of voters is a contextual process (cf. \textit{contextual effect}) and much of the social interaction that precedes a voting decision is locally based, in the household and \textit{neighbourhood} – hence the
considerable emphasis in electoral geography on the NEIGHBOURHOOD EFFECT. In addition, the mobilization of voters is also at least partly a spatially specific activity, with political parties focusing their electioneering on those places where they expect to get the best returns.

Much analysis in electoral geography uses ecological data – often combining electoral returns for places with census data on the characteristics of their inhabitants – and thus faces problems associated with ECOLOGICAL INFERENCE (cf. ECOLOGICAL FALLACY; MODIFIABLE AREAL UNIT PROBLEM). Geographers have also added spatial information to survey data, facilitating analyses that at least partially circumvent those problems, although in the USA studies of patterns of voting by state and Congressional District have produced substantial insights into the political economy of elections there (Archer and Taylor, 1991).

In many electoral systems – especially those based on single-member constituencies (the so-called first-past-the-post system, deployed in both the UK and the USA) – the translation of votes into seats in the relevant legislature is an inherently geographical process, with the membership of such bodies determined by who wins most votes in each of a set of territorial constituencies. Constituency-delimitation (cf. REDISTRICTING) can thus be highly politicized in some countries, with district boundaries defined to promote the interests of one party over those of another, although similar outcomes may result without any such activity when redistricting is undertaken by independent, non-partisan, bodies (Gudgin and Taylor, 1979: cf. DISTRICTING ALGORITHM; GERRYMANDERING; MALAPPORPTION). As part of their continued mobilization of support in places, parties and/or candidates may influence the allocation of PUBLIC GOODS towards favoured areas, both to reward those who have supported them at past contests and to solicit support from others there (cf. PORK BARREL). The geography of election results is thus a potential foundation for a GEOGRAPHY of political POWER. (See also DEMOCRACY.) RJ

emigration A particular form of MIGRATION: the term is usually reserved for migration that occurs between countries. To emigrate is to leave a place, the opposite of IMMIGRATION, to enter a new place. Emigration was defined as a basic HUMAN RIGHT in Article 12 of the 1966 UN International Covenant on Civil and Political Rights (which came into force in 1976): ‘Everyone shall be free to leave any country, including his [or her] own’ (United Nations, n.d.). Note that the right to emigrate is not matched by the right to immigrate, or to enter the country of one’s choice. The value of this right is therefore debatable. Furthermore, countries vary widely in their observance of this right. During the COLD WAR period, STATES within the Warsaw Pact typically prohibited their citizens from leaving, especially after walls were built to separate the CAPITALIST and state SOCIALIST countries of Europe. The number of countries that currently prohibit emigration is limited, but all NATION-STATES regulate exit to a degree through the granting, or withholding, of passports (Torpey, 2000). Countries also differ in their practices of monitoring emigration: some track their citizens abroad through registration systems, and collect detailed statistics on all entries and departures, while others are only interested in citizens who are actually resident in the nation-state (see also CITIZENSHIP). emotional geography The study of the dynamic, recursive relation between emotions and PLACE or space. Emotional geography includes diverse ways of understanding the differential TOPOI and TOPOGRAPHIES of emotion. As a body of work it responds, on the one hand, to the claim that emotions are an intractable aspect of life and thus potentially a constitutive part of all geographies (Anderson and Smith, 2001) and, on the other, to the recognition that emotions have long been manipulated and modulated as a constitutive part of various forms of POWER (Thrift, 2004a). As such, work on emotional geographies elicits the multiple ways in which different emotions emerge from, and re-produce, specific socio-spatial orders and engages with how emotions become part of the different relations that make up the lived geographies of place (Davidson, Bondi and Smith, 2005). Consequently, the term ‘emotional geography’ does not designate a sub-discipline limited to the study of a set of emotions (such as fear, boredom or anxiety). Rather, it is composed of ways of considering how emotions, along with linked modalities such as feeling, mood or AFFECT, are constitutive elements within the ongoing composition of SPACE–TIME, and exploring how learning to
respond to and intervene in such modalities could or perhaps should disrupt human geography’s methodological and theoretical practices.

Attention to emotions, or at least calls to attend to emotions, have a long history in human geography, being central, for example, to the expansive version of what a human is and does that was articulated by humanistic geographies in the 1970s and, in particular, to feminist interventions in social geography (e.g., on fear, Pain, 2000). Current work on emotional geographies is animated by two intertwined sources – both of which resonate with the attention in humanistic geography to the lifeworld and the taken-for-granted world, and perform a sensibility that attends to the ebb and flow of everyday life. First, and most prominently, there is the careful attention to emotional experience and the subsequent attempts to reclaim and give voice to emotional experiences. Second, attention is paid in non-representational theories to the emergence, or individuation, of emotions from within more or less unwilled assemblages that gather together human and non-human bodies in broad fields of affect. These are by no means mutually exclusive or internally coherent perspectives – indeed, what is shared between them is a commitment to the relationality of emotions and thus an assumption that emotions are not contained by, or properties of, an individual mind. Yet the resulting theoretical and methodological pluralism raises questions about how to understand the role of the subject in what an emotion is and does, as well as broader questions of how to develop conceptual vocabularies attentive to differential emotional geographies. Both questions have been responded to through the recent experimentations with techniques such as practical psychotherapies (cf. psychoanalytic theory) and performative methods (see performativity) that aim to witness different emotional or affectual geographies (cf. Tolia-Kelly, 2006). The importance and interest of this new body of work is reflected in the publication of a new interdisciplinary journal, Emotion, Space and Society (2008–).

**empire** An extensive territory and polity, encompassing diverse lands and peoples, that is ruled, more or less directly and effectively, by a single person (emperor/empress), sovereign state or centralized elite, and without the formal consent of all its peoples (cf. Lieven, 2005). The term is also used colloquially to denote great power and transcendent influence (as in ‘corporate empire’ and ‘reason’s empire’), and the adjectives ‘imperial’ and ‘colonial’ are commonly used to characterize actions and processes befitting empire.

Empire has taken diverse forms and eludes a single meaning or explanation. Parallels have been drawn between the evolution of Europe’s modern colonial empires, which reached their heyday in the early twentieth century, and since Roman times the ability to stretch power over space has figured centrally in debates about empire (see time-space distanciation). There have been over 70 empires in history – including those created by the Romans, Incas, Habsburgs and Ottomans, and by Britain, Japan and the Soviet Union – and Niall Ferguson (2004, p. 11) typologizes them in terms in their metropolitan foundations, declared aims, economic and political systems, social character, and perceived benefits and drawbacks. Important distinctions have been drawn between ancient and modern, Western and non-Western, maritime and land, and formal and informal empires. And histories and theories of empire have long varied in accordance with: (a) the relative importance given to six sources of power (economic, military, political, geopolitical, demographic and ideological); (b) the ways and extent to which sovereignty is seen as unified or divided, and power as centralized and totalizing or limited and localized; and (c) the impact that empire has on the identity of colonizing and colonized peoples (Pomper, 2005).

The term derives from the Latin word **imperium**, meaning ‘sovereign authority’, and since the nineteenth century has been closely associated with imperialism and treated as pivotal to the globally uneven development of capitalism. Empire has long been used as a term of abuse – as quintessentially exploitative, and the duplicitous means by which the West has sought to impose its values and institutions (of reason, civilization, progress, democracy and so forth) on others. But over time, and still today, empire has also been viewed in a more affirmative light – as tolerant of difference, as a civilizing and modernizing influence, and as the harbinger of global order and a higher (perpetual) peace.

In recent years there has been a major revival of interest in empire, which is tied to three sets
of (interrelated) factors. First, there has been a resurgence of scholarly interest in the history and legacies of colonialism – one marked by a comparative turn in the study of world history that questions both eurocentric and nation-centred histories of empire, and a heightened concern with the ‘culture of empire’ (Hall, 2000). Second, there has been vigorous debate, particularly since 9/11, about whether the USA should be regarded as an empire – ‘empire lite’ and ‘empire in denial’ being important slogans in the debate (Dædalus, 2005: see American empire). Third, this debate feeds into a wider discussion of whether globalization is better characterized as what Michael Hardt and Antonio Negri (2000, pp. xii–xiii) see as a new age of empire that ‘establishes no territorial center of power and does not rely on fixed boundaries and barriers . . . a decentred and deterritorializing apparatus of rule that progressively incorporates the entire global realm within its open, expanding frontiers’ (cf. biopolitics).

Since the late 1980s, an increasingly diverse geographical literature has critically examined the historical links between geography (as both a discipline and discourse) and empire, sensitizing geographers to the Western-imperial-white-male biases and assumptions embedded in their disciplinary fabric. Close critical attention has been paid to how ‘geography’s empire’ (Driver, 2001a) was fashioned at the level of knowledge and representation – as a form of epistemological violence – through practices of exploration, mapping and landscape representation, and deterministic and divisive discourses on climate and race (Clayton, 2004; cf. geography, history of). But geographers have also taken on board a wider interdisciplinary attempt to complicate understanding of empire’s rigid geography of core and periphery by recovering a community of struggles over who was included and excluded in definitions of empire and nation, how lines and boundaries of difference were drawn between citizen and subject (see citizenship), and the specific – and class-, race- and gender-inflected – imperial and colonial locations (from museums to plantations) in which such dynamics were enacted and settled (Proudfoot and Roche, 2005).

Recent geographical research bears witness to the contemporary liaison between geography and empire in two further – if contrary – ways: first, through geohazards research and an emboldened military geography, which are fired by GIS technologies and government contracts, and which serve the perceived security and surveillance needs of Western states; and, second, through geographers’ oppositional engagement with America’s so-called ‘war on terror’ (see terrorism). In two important studies of the historical and contemporary geography of American imperialism, Neil Smith (2003c) uses the political influence of Isaiah Bowman – ‘Roosevelt’s geographer’ – to question teleological accounts of the passage from empire to nation-state to globality, and recover the imperial spatiality of American visions of global development; and Derek Gregory (2004b) explores the spatial strategies and tactics – ‘colonising geographies’ – created and deployed by the USA and its allies in the Middle East, showing how the USA now bestrides a ‘colonial present’ in which it exempts itself from international laws, institutions and limits on behaviour, creating ‘spaces of exception’ (of confinement, banishment and punishment) that strip people of their dignity and most basic human rights (cf. biopolitics; exception, space of).

Three important insights that can be gleaned from this range of recent work are that: (a) past empires were less state-centred than was previously thought, and current US imperialism is more centred on the projection of nation-state power than contemporary theorists such as Hardt and Negri have proposed; (b) it is possible to analyse empires as both unitary and fragmentary, and as potent yet vulnerable apparatuses of power; and (c) historical work on empire, and the recognition it brings of the diverse ways in which power has and can be exercised, is key to understanding the nature and limits of empire today.

Empiricism A philosophy originating with the Greeks, and later formally codified by the English philosopher John Locke (1632–1704), that privileges experience of the outside world above all else as the basis of knowledge, truth and method. The contrast is with philosophies that favour intuition, or self-revelation, or rationalism; that is, philosophies underpinned by internal mental processes independent of external senses. Empiricism most overtly entered human geography through the discipline’s use of the standard scientific method, which was most self-conscious during the 1960s, but which existed both before and after in less explicit forms. This method
is unabashedly empiricist, averring that scientific theories and hypotheses are verifiable only against the gold standard of empirical data; that is, data observed though the senses. Nothing else counts. During the 1960s, this version of the scientific method and its concomitant empiricist philosophy was explicitly introduced into geography as part of the quantitative revolution (Harvey, 1969). Ironically, though, what was so novel about ‘the revolution’ was the introduction of rationally derived theory, exactly the kind of pursuit most anathema to empiricism. This eventually clarified a crucial distinction between empiricist enquiry, which assumes that ‘the facts’ (observations) somehow speak for themselves and are independent of theory, and empirical enquiry, a substantive study that may be (and usually is) sensitive to the interdependence of theory and observation.

empowerment Defined by alternative development thinkers (Friedmann, 1992) as a process by which households and their members wield greater socio-political and psychological power (e.g. knowledge, skills, voice, collective action, self-confidence) to reshape the actions affecting their own lives, empowerment has come to mean different things for different players. While mainstream development agencies regard empowerment as a tool to improve efficiency, more alternative agencies claim it as a metaphor for fundamental social transformation. Still, ‘empowerment as praxis’ retains its localized, personal emphasis as a phenomenon that necessitates individuals and collectives to struggle towards new consciousness and actions (Parpart, 2002) (see also post-development and anti-development).

eclave A small piece of territory that is culturally distinct and politically separate from another territory within which it is located. ‘Enclave’ originally referred to a territory situated within a state but outside its political jurisdiction, such as the Vatican City in Italy. The term is also used to denote areas in which a minority population that identifies with one state is located in the territory of a neighbouring state, such as Ngorno Kharabach, which is an enclave within Azerbaijan but has an Armenian population. The term is increasingly used to refer to a city neighbourhood displaying distinctive economic, social and cultural attributes from its surroundings. (See also exclave.)

Suggested reading Aalto (2002); Parks (2004).

enclosure In historical geography, enclosure refers to the extinction of ‘common rights’ and the replacement of open or common fields, pastures and meadows with ‘enclosed’ fields free of such rights. Across large swathes of medieval and early modern Europe, much agricultural land was common land that was subject to various forms of use by all individuals holding ‘common-rights’ (De Moor, Shaw-Taylor and Ward, 2002). These included rights to graze animals on common pasture and sometimes the right to gather fuel; rights over common fields, where individual cultivators might own a large number of scattered strips of arable land that alternated seasonally between private cultivation of the strips and communal grazing by those with common rights; and rights over common woodlands. Such common rights were not available to everyone, and were regulated by institutions such as manor or village courts. Enclosure replaced common land with fully private land that in some regions was physically ‘enclosed’ by a hedge, wall or ditch – within its boundaries, the owner or tenant normally has exclusive rights to use that land.

In England, the parliamentary enclosures of the eighteenth and nineteenth centuries are the best known, but enclosure began in the Middle Ages. It become an important process during the fifteenth century and probably peaked during the seventeenth century. Elsewhere in Europe, enclosure tended to come much later, principally during the nineteenth and twentieth centuries (as in the Soviet Union), though some common land still survives. In England, much medieval enclosure may have taken place by seigniorial edict, and is often associated with the conversion of arable to pasture and the destruction of villages (there are over 3,000 deserted medieval village sites known to archaeologists), but certainly by the early seventeenth century, and probably by the early sixteenth century, tenurial security had improved to the point at which it was legally necessary to secure the written consent of all proprietors, giving even the smallest owner an effective veto. Such enclosures by agreement became increasingly difficult to secure and during the eighteenth century, particularly after 1750, enclosure by agreement generally gave way to parliamentary enclosure. This required an Act of Parliament that allowed the larger landowners to override the vetoes of small
The importance of enclosure in England has been stressed in three major historical processes. First, enclosure reshaped the landscape. Second, enclosure was entangled with the destruction of the English peasantry (see Peasant) and the rise of agrarian capitalism, though its importance remains a matter of debate (Humphries, 1992; Neeson, 1993; Shaw-Taylor, 2001). Third, enclosure played an important role in raising agricultural productivity during the agricultural revolution (Overton, 1996). By allowing farmers to specialize in the most profitable crops, enclosure facilitated regional specialization and thus higher overall productivity, and enclosure was also a precondition for certain technological changes in agriculture; for example, installing under-drainage or the selective breeding of animals.

While enclosure has been subject to long-standing historical scrutiny, more recent work has also begun to reinterpret the concept of enclosure as a means of exploring the contemporary forms and processes of neo-liberalism (see Retort, 2005). Human geographers have seized upon enclosure as an ongoing feature of capital accumulation. Whereas traditional historical accounts of enclosure emphasized its relationship to ‘the commons’, recent work has proposed a more complex spatial formation operating across a number of scales, sites and practices, from special economic zones to genetic modification and biometrics (see biopower). Three major axes of investigation have been identified (Vasudevan, McFarlane and Jeffrey, 2008). The first focuses on the role of enclosure as a technology of contemporary neo-liberalism. Narratives of enclosure help illuminate the reconfiguration of political sovereignties, modes of subjectification and neo-liberal economic norms through a variety of territories and networks. The second explores the role of law as a key instrument through which both old and new forms of enclosure are legitimized, regulated and policed. The third addresses the significance of enclosure as a key dimension of our colonial present. While studies of colonialism underline the importance of land tenure as a precondition for particular forms of displacement, dispossession and discipline, contemporary instances of imperial enclosure have also mutated into new forms of the enclave capitalism that has accompanied the securitization of global mineral extraction (see Ferguson, 2006). Such an expansive re-conceptualization of enclosure has highlighted not only a complex set of logics of spatial inclusion and exclusion, but increasingly urgent forms of resistance that centre on a messy and highly conflicted reclaiming of the ‘commons’.

De Moor, Shaw-Taylor and Warde (2002); Mingay (1997); Vasudevan, McFarlane and Jeffrey (2008).

dendogenity The property that a variable is determined within a model or geographical system, rather than being ‘exogenous’ or determined outside the model and so taken as fixed. In statistical models such as regression and the generalized linear model, the right-hand side or independent variables are assumed to be exogenous, but situations arise where they are in fact endogenous, creating problems for model estimation. One widely applied example is in fiscal competition and ‘tax-mimicking’ between neighbouring local or regional governments (such as states within the USA): a state or local government’s expenditure (or tax-rate) is determined by several (exogenous) characteristics of the state but also by the expenditure (or tax-rate) behaviour of neighbouring states, so that there is spatial endogeneity; such models are an important topic in spatial econometrics. A second example is where school pupil performance levels are influenced by the average income levels of families within the school catchments: the family income levels are assumed to be exogenous, but affluent families may have moved to the catchments of high-performance schools, and so not be exogenous after all, the so-called ‘selection problem’ in estimation. There are several methods for taking endogeneity into account in the estimation process, including instrumental variables, maximum likelihood and Bayesian analysis, all of which are employed in spatial econometrics. For studies employing individual-level data (as in some pupil performance analyses), there is a technique of ‘matching’ the characteristics of individuals between areas to eliminate endogeneity bias.

Suggested reading
energy The capacity of a physical system for doing work. All species harness energy. Human beings harness, convert, release and (re)deploy energy to do work and yield goods and services. This is the basis for the material evolution of human societies. While all life forms ultimately depend on solar energy, since the INDUSTRIAL REVOLUTION developed countries have increasingly relied on non-renewable resources for energy.

Worldwide energy consumption is increasing. This is partly due to increases in global population, high levels of energy consumption in developed countries, and rising energy use in rapidly developing economies such as China and India. Per capita energy consumption varies significantly throughout the world. It is also important to recognize patterns of economic activity; for example, energy is consumed in developing countries to make cheap products for export to wealthier countries. Despite increased efficiencies in energy consumption in most developed countries, redistribution in energy consumption has occurred. Reducing material consumption, reusing existing materials and recycling may achieve reductions in energy demand. Human geographers have studied cultural and urban aspects of energy use, including transitions to more sustainable cities (Pacione, 2001a).

Reduction in the use of energy through improved design, greater insulation and changes in use patterns can lower economic costs to an organization. Businesses have worked with parts of the ENVIRONMENTAL MOVEMENT on energy efficiency since the oil crises of 1973 and 1979. These crises signalled the end of cheap, abundant oil and highlighted the dependency of industrialized countries on the Organisation of Petroleum Exporting Countries (OPEC), and the vulnerability of economies in some developing countries (see von Weizsacker, Lovins and Lovins, 1997).

Major concerns about energy include the continued supply of oil and the cumulative impacts of fossil-fuel consumption (see GLOBAL WARMING). Predictions of 'peak oil' at the scale of individual oilfields, countries and the globe highlight the finite nature of this NATURAL RESOURCE (Deffeyes, 2001). Every year, the world consumes billions of barrels of oil more than are discovered. Estimates of known reserves in various countries are not always reliable. Therefore, regardless of the environmental impacts of oil consumption, other sources of energy are required to continue present levels of economic activity. Natural gas (the cleanest-burning fossil fuel) is gaining importance, wind power is increasing rapidly from a low base and 'hybrid' cars are gaining popularity. The nuclear industry is advocating nuclear energy as an alternative to fossil fuels to combat global warming.

The dependence on fossil fuels inhibits the transition to renewable forms of energy such as solar, wind, biomass, hydrogen fuel cells and wave power. While fossil fuels are subsidized (Riedy and Diesendorf, 2003), the cost of renewable energy forms is not reduced significantly, due to inadequate research funding and difficulties in achieving ECONOMIES OF SCALE in production processes. Total world energy demand is anticipated to grow, despite efforts at reduction through greater efficiency. SUSTAINABILITY is crucial, including the use of appropriate technologies and energy sources in developing countries, transitions to benign energy sources throughout the world and reductions in energy use in developed countries.

Enlightenment In traditional interpretations, the Enlightenment is held to be that period of intellectual enquiry, broadly synonymous with the 'long' eighteenth century in Europe (c.1680–1820), in which ‘modern’ ideas of rationality, public criticism and the emancipation of CIVIL SOCIETY through reasoned reform took shape. Thus considered, the Enlightenment was distinguished by challenges to established ideas of ‘ancient authority’ and by the rejection of Classical and Renaissance conceptions of the world and of ‘traditional’ scholarship. PHILOSOPHY and SCIENCE were widely believed to be the basis to universal social betterment. Secular tolerance would overcome religious intolerance. In sum, humankind would free itself from ignorance and error.

Other interpretations are current. Indeed, even during its development and certainly since, the Enlightenment has been the subject of detailed scrutiny as to what it was, why it happened and what its consequences have been. Conventional views of the Enlightenment as a largely philosophical and uniform phenomenon evident in urban Europe especially in the lives and writings of great men, have been decisively challenged (Schmidt, 1996; Kors et al., 2003). Conceptions of the Enlightenment as a ‘moment’ of philosophical critique for a European elite (which still endure: see Darnton, 2003) have been supplemented by views of it as a SOCIAL MOVEMENT. Ideas of the Enlightenment as a uniform intellectual movement with particular national expression have been challenged by work that
stresses Enlightenment, even enlightenments, as a social process or processes. As study of the Enlightenment has become more diverse – embracing, for instance, medical knowledge, questions of gender, exoticism, race and sexuality – so studies of the Enlightenment have diversified (Outram, 2005). Questions of geography are central to these revised and revitalized conceptions of the Enlightenment (Livingstone and Withers, 1999).

In traditional interpretation, little attention was paid to the geography of the Enlightenment. Where it was, emphasis was given to its distinctive features and differences at the level of the nation-state, chiefly within Europe. Attention concentrated upon the idea of the Enlightenment’s originating cultural hearth or its ‘core’ nations – France, England, Scotland, Holland, Germany – and to a ‘periphery’ where the Enlightenment was evident later or in different form: in Russia, for example, or in the Scandinavian countries. Relatively limited attention was given to the Enlightenment in the Americas and to its presence and making in Portugal, Spain or the Greek-speaking countries of Eastern Europe (Porter and Teich, 1981). More recent work has moved beyond these concerns and scales of analysis. Three distinct but interrelated themes may be noted.

The first is geographical knowledge and the Enlightenment. Geographical knowledge, gleaned through oceanic navigation, terrestrial exploration, mapping and natural history survey, was crucial in the Enlightenment to new ideas about the shape and size of the Earth, terrestrial diversity and the nature of human cultures. In this first sense, the Enlightenment depended upon new geographical knowledge about the extent of what European contemporaries understood as terra incognita and then called the ‘fourth world’, the Americas, and, crucially, about the ‘fifth division’ of the world, the Pacific world or, in modern terms, Australasia. For example, one distinctively Enlightenment idea (and ideal), that of society’s development through a series of stages, was profoundly shaped by the ‘discovery’ of new peoples on the islands of the Southern Oceans, and by the extent of human cultural difference. Contemporaries referred to these geographies of human difference as ‘The Great Map of Mankind’ and devoted considerable time to theories explaining the development of human society in relation to factors such as climate, the role of custom and commercial capacity. In such ways, Enlightenment was closely connected with empire (see also TRAVEL WRITING).

We may secondly think in terms of geography in the Enlightenment. Geography as one form of modern intellectual endeavour was itself shaped by the evolving encounter with new peoples and lands during the Enlightenment. This was apparent in terms of emphases upon realism in description, systematic classification in collection and comparative method in explanation. Geography in the Enlightenment was a discourse, a set of practices by which the world was revealed and ordered, and it was a discipline and a scale of study, the whole Earth, in which formal education was possible, in schools and universities. It was also a popular subject, taught in academies and in public lectures alongside history, astronomy and mathematics, in order to educate citizens about the extent and content of the globe (Mayhew, 2000). In these ways, geography in the Enlightenment was part of what thinkers then called ‘The Science of Man’, that concern to understand the human world through the same observational and methodological principles as the natural world (see also GEOGRAPHY, HISTORY OF).

Finally, it is now commonplace to refer to the different geographies of the Enlightenment. These different geographies are distinguished by attention to the intrinsic diversity of the Enlightenment, to the social processes and contradictions underlying its intellectual and practical claims and, above all, by sensitivity to the importance of geographical scale in locating and explaining the Enlightenment and its constituent practices. Although the Enlightenment continues to be much studied in national context, greater attention than before is now paid to its global expression and consequences, to the local institutional sites and social settings in which the Enlightenment’s defining ideas were produced and debated, to the uneven transmission of those ideas across geographical space and to the variant nature of their reception (Clark, Golinski and Schaffer, 1999; Livingstone and Withers, 1999; Cañizares-Esguerra, 2001).

Questions to do with the ‘where’ of the Enlightenment are thus as important as those of its ‘what’, ‘why’ and ‘who’. Many of the architects of POSTMODERNISM have speculated on the end of what, ignoring its diversity, they have sometimes clumsily termed the ‘Enlightenment Project’ (Geras and Wokler, 2000). Whilst initially critical of Enlightenment writers’ emphases upon rationality, reform and the power of critical argument, many such theorists would now confirm the enduring significance of the Enlightenment as a set
of critical political issues and as an object of historical and geographical study.

enterprise zone An area in which special policies apply to encourage economic development. Enterprise zones typically offer tax concessions and reduced planning and other regulations to private companies. Critics argue that their effect is often to move existing jobs rather than to create new ones, and that they produce a concentration of power in the central state and a loss of control by the local state over development strategies. Enterprise zones are common in the USA and the UK, but similar arrangements are found in many countries, including export-processing zones, special economic zones (notably in China and India) and tax- and duty-free zones.

entrepreneurship The geography of entrepreneurship explores the relationship of entrepreneurship to space and place; to date, interest has focused mainly on identifying the characteristics of places that foster the formation of businesses in high-technology industries. This kind of entrepreneurship has interested economic geographers because of its presumed importance to innovation and to regional economic growth and development. In his review of the literature on entrepreneurs, networks and economic development, Malecki (1997) points to the importance of regional industrial mix, skilled labour, the spatial concentration or agglomeration of similar industries, and networks that provide access to technology and capital. He concludes, however, by noting how relatively little is known about the relationship between entrepreneurship and territory. (For the entrepreneurial behaviour of places, see urban entrepreneurialism.)

The culture of entrepreneurship is another place-based characteristic that affects economic development trajectories. In her comparison of the high-technology clusters of Route 128 outside Boston, Massachusetts and Silicon Valley in the San Francisco Bay Area of California, Saxenian (1994) underlines the importance of cultural difference (in patterns of networking, in degrees of hierarchy in organizations, and in the amount of formality expected in the organization of work, for example) in shaping economic outcomes (growth versus stagnation).

In view of the degree to which social structures are gendered and racialized, characteristics of the entrepreneur affect the relationship of entrepreneurship to place. Feminist geographers have pointed to the importance of the gender of the entrepreneur and the ways in which gender shapes the meaning of innovation (what is considered innovative in a place) as well as an entrepreneur’s access to resources; female-owned businesses often contribute to the development of places differently from male-owned businesses, and women entrepreneurs have greater difficulty obtaining bank loans, although this difficulty varies significantly from place to place even within a metropolitan area (Blake and Hanson, 2005). Entrepreneurship among members of ethnic groups is facilitated by ethnic ties, some of which may stretch to other countries, which enhance access to resources (Zhou, 1998; see ethnicity).

Much remains unknown about the relationship of entrepreneurship to place and space. For example, how does local context relate to the formation and nurturing of firms in non-high-technology industries? How do different kinds of businesses and business owners contribute to local economic and social well-being? How does local context enable and constrain the process of business ownership for different kinds of people?

entropy A measure of the amount of uncertainty in a probability distribution or a system subject to constraints. The term originated in thermodynamics, but has been used in a wide variety of contexts, notably in information theory and as the basis for entropy-maximizing models of spatial interaction.

The concepts of macrostate and microstate are central to entropy analysis. Consider the distribution of 100 people into 10 regions: individual B to region six, individual K to region four and so on. A macrostate is an aggregate frequency distribution of people across regions. Several different microstates may correspond to or give rise to the same macrostate: different individuals go to different regions, but the frequency distributions are the same. Entropy measures the relationship between a macrostate and the possible microstates that
ENTROPY-MAXIMIZING MODELS

correspond to it. At one extreme, one macro-state (all 100 people in one region) has only one associated microstate, whereas the macro-state with 10 people in each region corresponds to a large number of different microstates. The number of microstates corresponding to a macrostate is denoted here by $W$, and finding the entropy measure is a combinatorial calculation, given by

$$W = N! / \prod_i n_i !,$$

the factorial of the total number of individuals $N$, divided by the product of the factorials for each $n_i$ (the number in each region). An alternative, but equivalent, measure is that used in information theory.

entropy-maximizing models Statistical models for identifying the ‘most likely’ spatial allocation pattern in a system subject to constraints. The approach was introduced into geographical modelling by A.G. Wilson (1967) as the basis for a more rigorous interpretation of the GRAVITY MODEL, and has been extensively used since for SPATIAL INTERACTION modelling in urban regions and for modelling inter-regional flows of traffic and commodities. It is based on the concept of ENTROPY, a measure of the uncertainty or ‘likelihood’ in a probability distribution. A journey-to-work model illustrates the method. For a city divided into $k$ zones, we wish to calculate the best estimate of interzonal commuting flows $T_{ij}$ without knowing the detailed information of each individual movement. Assume that there are $N$ total commuters. Any specific trip distribution pattern $T_{ij}$ known as a ‘macrostate’ (see ENTROPY), can arise from many different sets of individual commuting movements, or ‘microstates’, and entropy measures the number of different microstates that can give rise to a particular macrostate. In the absence of detailed microstate data, we assume that each microstate is equally probable, and that the macrostate with the maximum entropy value is the most probable or most likely overall pattern. Additional information is also normally available, notably the number of commuters originating from each zone, the total number of jobs available in each zone, and estimates of the average or total travel expenditure for the city, $C$ (usually based on survey data). The entropy-maximizing method then consists of maximizing the entropy measure subject to these constraints. This maximization is a non-linear optimization problem, and must be solved by iterative search methods. These models not only fit empirical trip-distributions well, but also facilitate easy calculation of the effects of new housing or jobs (by altering the constraints), and so have been widely used in more general urban models. Wilson and his Leeds colleagues have extended the model in many ways, making it dynamic, linking it to industrial and urban LOCATION THEORY, and including several types of disaggregation (e.g. by mode of travel).

environmental audit Environmental auditing originated in the 1970s as a management tool to evaluate how well a corporation was complying with the complex array of environmental legislation that was emerging as a result of the ENVIRONMENTAL MOVEMENT. It is an important part of environmental management systems (EMS).

Environmental audits are an ‘official examination and verification of accounts and records to assess how close the situation comes to meeting a set requirement’ (Thomas, 2005, p. 236). They are a one-off collection of data, and therefore differ from ongoing monitoring activities. Environmental audits may be internal to a corporation, produced externally, undertaken voluntarily or to fulfil legal requirements, and may check compliance with regulations or focus on a company’s systems to achieve and maintain compliance (de Moor and de Beelde, 2005). Environmental audits may be undertaken for governments, aid agencies, financial institutions and community groups. Internal environmental auditing helps companies meet regulations and their own environmental goals in a cost-effective manner. Mandatory, external auditing verifies and encourages compliance with environmental regulations. Who undertakes the environmental audit and who has access to the resulting document are questions about the regulation of industry and commerce. Environmental auditing is situated within larger debates about how to achieve and maintain high environmental quality.

environmental determinism A type of reasoning that holds that the character and form of a SOCIETY, CULTURE or BODY can be explained by the physical conditions within which it has developed. Determinism is a form of explanation that finds no place for other
factors, outside forces or random features. All creativity and productivity is assigned to first causes, in this case to environmental conditions. Social and human diversity is explainable, this doctrine would hold, solely in terms of the environments within which they develop. In this sense there is a strong assumption that NATURE and CULTURE exist as a dualism, and that cultures are shaped by Nature. While it is accepted that cultures interact with environments, and may alter them, it is nevertheless argued that the conditions for doing so are shaped by the larger environment. There are two major forms of critique of environmental determinism. The first is a form of HUMANISM, arguing that far from being reduced to their physical conditions, human beings can transcend those conditions through, variously, ingenuity, spirit, technology and social organization. However, such arguments tend to reproduce rather than overcome the Nature/Culture dualism, and can result in forms of voluntarism and IDEALISM. The second is a more MATERIALIST argument, suggesting that people and environments continuously evolve in relation to one another, and in doing so necessarily co-produce one another. In these versions, determinism is debunked not because of any transcendent human capacity, or any mysterious element, but through the sheer randomness of matters in relation.

Environmental determinism has a long and varied history, from the ancient Greeks (notably Aristotle’s climatic zones), the Renaissance (notably Montesquieu’s Heaven and Earth), to post-Darwinian writers (Glacken, 1967). From the late nineteenth to the mid-twentieth century, it is often argued that GEOGRAPHY was complicit, through its environmental determinism, with a north European supremacist that linked human ‘achievement’ and DEVELOPMENT to environmental conditions (Livingstone, 1992). Friedrich Ratzel in Germany and Ellen C. Semple in the United States perhaps best captured this geographical tradition. Yet even here, and certainly in later writings of other environmental determinists, the arguments were barely as clear cut as might be supposed. Ó Tuathail (1992) demonstrates Halford Mackinder’s partial FOUNDATIONALISM, where in he ceded to humans the POWER to transcend formative environmental conditions. Twentieth-century schools sought to blur the lines of explanation, giving rise to such terms as POSSIBILISM and PROBABILISM. The latter terms are most often associated with the French school of geography, most famously Paul Vidal de la Blache. Yet, rather like the BERKELEY SCHOOL and later forms of Marxist and Russian geography, the notion that nature conditioned subsequent actions remained.

Despite this recurrent NATURALISM and its essentialist and FOUNDATIONAL tones, many of these works repay close scrutiny in a discipline that has been all too keen to leave non-human matters aside. The task is now to avoid any lurch to the cultural in an attempt to leave environmental determinism behind once and for all, and instead to return to the indeterminate question of how it is that human and non-human histories and geographies are intertwined. Finally, how to account for the longevity of this form of explanation is itself a complex question, one that would require attention to processes as varied as scientific authority and forms of reasoning (see SCIENCE), COLONIALISM and academic discipline building.

evironmental economics A branch of MARKET-based economics that advocates applying economic instruments to solve environmental problems. Although environmental economics can be traced to earlier work in the 1920s, it emerged at the same time as the ENVIRONMENTAL MOVEMENT in the 1960s. At that time most academic, government and corporate economists were insensitive to the environmental impacts of economic growth. Environmental economists claim that the economic system, when the wrong price signals are given, is a major cause of environmental problems. The main solution pursued by environmental economists is to send the right price signals via market mechanisms. This approach is now among the most dominant approaches to diagnosing and managing environmental problems in developed countries. It is increasingly popular given the pro-market orientation of NEO-LIBERALISM that exists globally and dominates in particular countries.

Environmental economics is closely associated with NEO-CLASSICAL ECONOMICS and RESOURCE MANAGEMENT. It expands the reach of the market to factor in what environmental economists label an ‘EXTERNALITY’, thereby changing the pricing signals for existing market transactions or creating new COMMODITIES and markets. WATER trading, carbon credits (see GLOBAL WARMING) and pollution credits are all examples of environmental economics

Geographers have been concerned about the pricing of the environment, and particularly about how monetary values are attached to environmental ‘goods’ and ‘services’ through contingent valuation. Pricing approaches include willingness to pay (WTP) and willingness to accept compensation (either WTA or WAC). Clark, Burgess and Harrison (2000) highlight the weaknesses in contingent valuation, particularly a lack of understanding by many respondents of what they were valuing and how this information would be used. This is crucial because environmental economists rely on approaches that translate ‘human preferences’ into monetary values in order to create pricing signals and operate a market (see Thampapillai, 2002).

Environmental economics has been subject to considerable criticism. Some critics believe that pollution taxes are licences to pollute, and do not relate to the absorptive capacities of the environment or ethical questions about perpetuating pollution. It is seen as reformist, or tinkering, with markets. At best, it reduces the worst excesses of market forces, but it also justifies some environmental damage and it perpetuates market expansion through the commodification process. It does not call for an economic overhaul, as in the tradition of the more radical ecological economics approach, and it does not treat the environment as having existence in its own right. However, the approach is increasingly influential, and so it cannot be ignored.

**Environmental hazard** Sometimes known as a ‘natural hazard’, or popularly as a ‘natural disaster’, this item generally refers to geophysical events such as earthquakes, tsunamis, volcanoes, bushfires, drought, flooding, lightning and high winds that can potentially cause major economic damage and physical injury or death. Such events, for example earthquakes, will have differing impacts depending on their magnitude and the character of the affected area (e.g. a heavily populated area versus a sparsely settled area). Given the long-term involvement of humans as part of nature, a detailed analysis of so-called ‘environmental hazards’ often reveals significant human input (see hazard). The characteristics of an environmental hazard are that it was not directly caused by humans, it directly affects humans (unlike an extreme natural event in nature that does not directly affect humans) and it is often accompanied by a violent release of energy. The United Nations declared the 1990s the ‘International Decade for Natural Disaster Reduction’ (Mauro, 1995). The use of the terminology ‘natural’ perpetuates the false perception that humans play no part in these disasters. Geographical research in the 1990s increasingly stressed ‘disaster’ rather than ‘hazard’, thereby emphasizing the social and cultural issues and the humanitarian response needed when disaster occurs (White, Kates and Burton, 2001).

The distinction between environmental hazard and a human-made hazard has blurred. It can only be maintained if humans are seen as being separate from nature, rather than a species that has been part of nature for thousands of years. Today we experience physical events, the impacts of which are influenced by the actions of humans and other species, which in turn influence the character of future physical events.

Work in the United States on hazards and disasters emerged in the context of the nuclear threat and the Cold War. Geographical research found that despite heavy spending on dams, losses due to floods were increasing. This environmental hazard research was critiqued from Marxist geography. Smith and O’Keefe (1980) claimed that geographers in the tradition of positivism displayed three major ways of dealing with nature, and demonstrated this through ‘natural hazards’ research. The three major approaches are nature being seen as separate from human activity; where nature is seen as neutral but becomes hazardous when it intersects with human activity; or where humans are dissolved into nature. The first approach focuses attention on ‘natural causes’ of disasters, rather than human vulnerability. The second approach is seen as a technocratic agenda to control nature. The third approach is seen as Malthusian (see Malthusian model), because it blames the victims.

Today, many geographers question a ‘natural hazard’ and highlight the difference between a natural event (e.g. drought, which may be partly caused by human activity) and the consequences (famine). These differences are usually attributed to the structure and performance of social systems. Recent Deleuzian-inspired work by Nigel Clark (2005b) expands the notion of systems by considering the Earth as an open system when exploring conceptions of nature, risk society, and the construction
of catastrophic events and their counterpoint, the notion of order in nature.

**Environmental history** Environmental histories reflect a basic desire to understand the relations between people and *nature* through time. Over the years, scholars have approached this broad and important topic from several disciplines. Anthropologists conducted ethnographic studies of the ways in which particular peoples conceived of, utilized and interacted with the natural (and supernatural) world. Archaeologists seeking the origins of domestication explored the earliest relations among people, plants and animals. Ecologists and other scientists sought to understand how human actions affected natural systems. Students of mythology, religion, and law traced expressions of human attitudes towards and concern for nature in medieval and Mesopotamian times. And after generations of philosophers had pondered the ways in which individuals living in different epochs conceived of the natural world, some among them came, late in the twentieth century, to argue against the very idea that ‘nature’ and ‘society’ are separate, distinct entities. In general, however, historians and geographers have led scholarship in this area.

In a manner reflected epigrammatically in the title of Marjorie Nicolson’s book, *Mountain gloom and mountain glory* (1959), historians such as Keith Thomas (1996 [1983]) and Roderick Nash (1967) traced changes in the ways that individuals and societies regarded nature or *wilderness* through the centuries. Others, including William Cronon (1983), Timothy Silver (1990) and Richard White (1980), considered what landscapes reflected of human endeavours, or found, with Mart Stewart (1996) and Harold Innis (1927), fruitful topics for enquiry in the ways in which economic development rested, in considerable degree, upon the natural endowments (that people thought of as resources) of particular territories. Geographers long held the study of human–environment relations to be one of the central ‘traditions’ of their field, and many of those with ecological and historical inclinations wrote at some length about the mutual shaping of lands and lives over time. In France, Paul Vidal de la Blache (1926), Albert Demangeon (1942) and Jean Brunhes (1952) all pursued investigations along these lines, and were among the giants of human geography early in the twentieth century. In the UK, some of the leading exponents of the developing subject, including Emrys Jones (1951–2, 1956), Estyn Evans (1960) and Harold J. Fleure (1951), were primarily interested in the relations between human societies and the natural environment (see also Langton, 1988). And in the USA, Clarence Glacken produced a classic work, *Traces on the Rhodian shore: nature and culture in Western thought from ancient times to the end of the eighteenth century* (1967), while Carl Ortwin Sauer, one of the convenors of the 1955 symposium on ‘Man’s Role in Changing the Face of the Earth’, led the study of human-induced landscape changes (Sauer, 1963a [1925]; Thomas, 1996 [1983]; Kenzer, 1986: see Berkeley School).

Still, the characterization of a particular field of enquiry as ‘environmental history’ is relatively new. By common North American assessments, it dates back to the rise of the environmental movement in the 1960s. There is merit in this view. As popular interest in environmental questions climbed, the spate of historical scholarship on the relations between people and nature through time – particularly in the USA – reached new heights. In addition, the parallelism between the coinage ‘environmental history’ and public anxieties about ‘environmental issues’ – which waxed and waned, but often seemed to be rooted in past practices (even if these were relatively recent) – served, brilliantly, to draw attention to the field. Quickly, the phrase ‘environmental history’ was adopted as a euphonious and readily understood label for a widely diverse and rapidly expanding body of work, even as it served to veil regional, national and disciplinary differences in emphases, origins and approaches to the study of human–environment relations. The field is now too large and varied to be encompassed in any single assessment, although a number of scholars have attempted to limn its developing dimensions (see, e.g., White, 1985; McNeill, 2003; Evenden and Wynn, 2009).

From the mid-1970s onwards, there were challenges to the dominant (American-centred) construction of the field. Three among these warrant brief notice. English-educated Richard Grove took issue with the common tendency, given particular substance by David Lowenthal, to identify the ‘Versatile Vermonter’ George Perkins Marsh as the fountainhead of the conservation movement, arguing in *Green imperialism* (1995) that awareness of human-induced environmental changes long predated Marsh’s work and was sharpened by observation of the effects of colonial expansion on ‘tropical island Edens’ (Lowenthal, 1958, 2000; Marsh, 1965 [1864]; Grove, 1995). In 1989, the Indian scholar Ramachandra Guha offered an important ‘Third world critique’ of American environmentalists’ fascination with wilderness...
preservation and their embrace of deep ecology. Arguing against the anthropocentric/biocentric distinction that marked current thinking on these matters, Guha (1989) insisted that efforts to extend wilderness protection worldwide had many harmful consequences for indigenous peoples, and urged environmentalists to place ‘a far greater emphasis on equity and the integration of ecological concerns with livelihood and work’. Meanwhile, anthropologists and geographers working on questions of development and underdevelopment in the global south coined the term political ecology to describe their interest in the linkages between political economy and cultural ecology (broadly, the relations between human societies and their natural environments). Political ecology is a broad church that has attracted many geographers – including, for example, Karl Zimmerer (Zimmerer and Bassett, 2003), Paul Robbins (2004), Roderick Neumann (2005) and Philip Stott (Stott and Sullivan, 2000), amongst others – for whom contemporary issues were more pressing than historical enquiry, sensu strictu, but many reached into the past to understand current circumstances, and the Journal of Political Ecology, established in 1994, promised ‘Case Studies in History and Society’ in its subtitle.

All of this made for something of an identity crisis in environmental history. A decade after Australian historical geographer Joe Powell suggested that the field reflected its practitioners’ collective will to believe in the field, American historian of science Harriet Ritvo described it as ‘an unevenly spreading blob’ (Powell, 1996; Ritvo, 2005). Responding to such challenges and seeking to define their enterprise, several environmental historians found order in diversity. According to one prominent American authority, environmental history proceeds on three levels. The first documents ‘the structure and distribution of natural environments of the past’. The second ‘focuses on productive technology as it interacts with the environment’. The third is concerned with the ‘patterns of human perception, ideology and value’ and the ways in which they have worked in ‘reorganizing and recreating the surface of the planet’ (Worster, 1990b). Another specialist claims that environmental historians ‘study how people have lived in the natural systems of the planet . . . how they have perceived nature [and how] they have reshaped it to suit their own idea of good living’ (Warren, 2003). A third American scholar differentiates environmental histories by the extent of their concern with material, cultural/intellectual or political matters (McNeill, 2003). Studies of the first type focus upon ‘changes in biological and physical environments, and how these changes have affected human societies’. Cultural/intellectual environmental history is concerned with ‘representations and images of nature in arts and letters’, and political environmental history examines ‘law and state policy as it relates to the natural world’. In a rather different vein, the English geographer Ian Simmons has given shape to his own form of environmental history in a number of sweeping book-length essays (Simmons, 1993, 1997, 2001).

Chaos theory and post-structuralism have also contributed to the (re)definition of environmental history. Thanks in part to the contributions of geographers such as David Demeritt (1994b, 1998, 2001a), Bruce Braun (2003), Noel Castree (1995) and Braun and Castree together (Braun and Castree, 1998; Castree and Braun, 2001), a field that rested, at its inception, upon a particular conception of scientific ecology (predicated on notions of stability and climax vegetation complexes), and upon a dichotomized view of nature and culture, has been forced, in recent years, to grapple with the question of ‘which nature and which conceptions of science should be brought in’ (Asdal, 2003: but see also, and more importantly, Worster, 1990a; Cronon, 1995). At the same time, a new awareness of the relations between knowledge and power (and an associated concern with questions of ethics and social justice) has rendered less satisfying the once-common declensionist narratives of environmental despoliation attributed to capitalist greed or human hubris. All of this has greatly complicated the stories that environmental historians tell. The field is broad and diffuse. It is also inherently interdisciplinary, and many of its practitioners are interested in providing perspective upon and contributing understanding to contemporary debates about human use of the Earth. Thus the field forms ‘a locus for exploration and intellectual adventure’, offering humans a spirited, reflexive understanding of themselves and their world (Weiner, 2005).

Suggested reading

Environmental Impact Assessment  A process of systematically identifying and assessing
anticipated environmental impacts prior to a proposed project, policy, programme or plan being implemented. The identification of significant negative impacts may prevent the proposal (which is usually a project) from going ahead. This is very unusual. More likely, it results in the modification of the original proposal, or the introduction of measures to ameliorate the anticipated negative environmental impacts. A proposal may generate positive environmental impacts, particularly if the site is already severely degraded, and these must be considered in the process.

Environmental Impact Assessment (EIA) was introduced in the USA in 1969 under the National Environmental Policy Act (NEPA). It is now a legal requirement in many countries, provinces/states and in some cities. International institutions such as the World Bank and international aid agencies also require an EIA process on particular development proposals. Initially, assessments were limited to federal departments in the USA, but EIA has expanded to include provincial/state and private development proposals, and developed from environmental protection to include sustainable development, a concept that emerged after EIA began.

There are numerous definitions of EIA. One succinct definition is ‘an assessment of the impact of a planned activity on the environment’ (in Glasson, Therivel and Chadwick, 2005, p. 4). The terminology varies between countries, and often causes confusion. For example, in some places EIA is simply known as ‘Impact Assessment’, because it is broader than a narrow definition of the physical environment. Elsewhere it is known as Environmental Assessment (EA) because of the perceived negative connotations of ‘impact’. In the USA, an EA is a preliminary study undertaken within the EIA process to identify the likelihood of significant impacts, which then require the preparation of a full EIS (Burris and Canter, 1997).

The process of EIA has become standardized and incorporated into planning and development processes in many countries. Under some legislative frameworks, the EIA document may be required to address issues such as sustainable development, biodiversity, social impacts and economic considerations. There are also legal requirements for public participation. Some jurisdictions include Social Impact Assessment (SIA) within EIA, while in other places it is a separate activity (see Glasson, Therivel and Chadwick, 2005; Thomas and Elliot, 2005).

Environmental Impact Assessment is sometimes seen as an important process that prevents the worst aspects of proposals from being implemented. It does not necessarily guarantee high-quality development. In contrast, other people perceive the process to be a way of legitimizing controversial development proposals. In their view, it does very little to maintain environmental quality. They argue that many of the key decisions have already been taken at the policy level, and that the individual character of EIA often fails to consider the cumulative impacts of each development. In some locations these concerns are partly being addressed by Strategic Environmental Assessment (SEA) at the policy and programme level (see Caratti, Dalkmann and Jiliberto, 2004) and Cumulative Impact Assessment (CIA). Glasson, Therivel and Chadwick (2005) and others advocate that an Integrated Environmental Assessment (IEA) addresses all of these considerations.

Environmental Justice The right of everyone to enjoy and benefit from a safe and healthy environment, regardless of race, class, gender or ethnicity. More specifically, environmental justice is a social movement that takes social justice and environmental politics as fundamentally inseparable. The movement has many divergent roots, such as the labour struggles of Cesar Chavez and Delores Huerta, and their crusade against the use of pesticides, in the 1960s; the community-based struggles of Lois Gibbs and others that arose from the dumping of toxic chemicals in lower-middle-class neighbourhoods at Love Canal, New York, in the 1970s; and in the responses of various offshoots of the civil rights movement to placing of toxic waste dumps, most famously in Warren County, North Carolina, in the early 1980s. Others contend that the most accurate date for the founding of the North American environmental justice movement is 1492. Whenever its origins, the movement currently stresses three major tenets. First, it gives attention to unequal exposure to hazards through specific policies and practices that intentionally or unintentionally discriminate against individuals, groups or communities based on race, ethnicity, class or gender (Bullard, 1994). Second, it has become more broadly attentive nationally and internationally to the ways in which these same communities are differentially denied access to and control over both resources and decision-making processes by institutions, corporations and individuals both in the USA and abroad (Neumann, 1998). Third, it has
become engaged in cultural politics involving the very framing of the key terms of the debate (acceptable risk, waste, race and environmental health) that conditions the political possibilities of the struggle for environmental justice (Fortun, 2001). The movement is known for its creative, engaged activism, its deep commitment to grassroots approaches to social change and its irreverence towards bureaucracy in-action. JK

**Environmental movement** A term that has been used to describe any social or political movement directed towards the preservation of natural resources, the prevention of pollution or the control of land use with the goal of conservation, restoration or improvement of the material environment. Though practices of environmental protection have been conducted in many places around the world for centuries, the movement as a modern phenomenon has its sources in different currents and critiques of modernity. Some of the main currents have their sources in critiques of industrial capitalism’s treatment of land and labour as commodities, others in transcendental, religious and aesthetic thought, still others in the practices of modern rationalist scientific knowledge, and yet others in a troubling search for nature’s ‘purity’. These and other tributaries have led to a deeply heterogeneous movement that has proven to be, in the best of times, a broad coalition of caring engaged critics and thoughtful visionaries of alternative futures and, in the worst, a deeply divided, exclusionary and even reactionary force for the reproduction of elitist and racist fears. Given this diverse history, it is no surprise that the movement has many current expressions, including political parties such as the Green Party, community non-profit organizations, international lending organizations, radical affinity groups, mainstream environmental organizations, legal advocacy firms, green corporations, and consumers, who operate through just as many diverse political techniques, including lobbying, scientific research, legislation, education, organizing and direct action. Regardless of its exact origins, members and strategies, the movement’s most powerful contemporary expressions seem to be found in international grassroots communities and organizations that challenge the violent effects of early twenty-first-century globalization. JK

**Environmental perception** A general term referring to the myriad ways in which actors (usually human) perceive, engage with and symbolically represent environments. Environment in this sense encompasses both the ‘natural’ and the ‘built’, and includes other people and animals as key elements. Equally, perception should be understood in the widest sense, referring to both the bio-psychological idiosyncrasies of individual sensing, information-processing and cognition, and the issue of collective cultural beliefs, values and aesthetic judgements concerning natural and built environments.

Although the study of environmental perception has never been a sustained core element of human geographical research, the topic has been investigated by writers from often quite different intellectual traditions. Early work on perception in geography, in the 1940s and 1950s, was concerned to highlight the importance of human perceptions, attitudes and values in shaping beliefs, understandings and decisions concerning the environment. Here, an acknowledgement of the nuance and complexity of human perception (and consequent behaviour) was intended as a corrective to human geographies that either ignored the human, or sought to understand human behaviour in solely rational or objectivist terms. The notion that human geographers should delve into the realms of human perception, meaning and value was further clarified in Kevin Lynch’s (1960) _The image of the city_, which sought to programatically investigate the relationship between an urban built environment and the mental perceptions of its inhabitants. Lynch’s work was seminal for _behavioural geographies_ through the 1970s and 1980s, especially insofar as these elaborated the notion of the mental map (Gould and White, 1993 [1974]) as a key element of environmental perception. For the most part scientific, quantitative and empirical in approach, these behavioural geographies connect with broader, interdisciplinary enquiries regarding the role of environmental perception and ‘value’ vis-à-vis the design and planning of urban and rural landscapes.

In contrast to the instrumental and objective approach to environmental perception characteristic of much work in the planning and
design fields, Yi-Fu Tuan’s (1974) *Topophilia: a study of environmental perceptions, attitudes and values* articulated a humanistic (see HUMANISTIC GEOGRAPHY), interpretative and mythopoetic approach to the topic. Tuan was mostly concerned with environmental perception at the collective cultural level and, in particular, with illustrating how symbolically meaningful and keenly felt relationships with the environment resonated deeply in both Western and non-Western cultures.

The humanistic approach advocated by Tuan and others fell from favour with the advent of critical and radical approaches emphasizing the study of socio-economic structures, and the salience and viability of subjective and emotional geographies of environmental perception was at risk through much of the 1980s and 1990s. However, over the past ten years, with the emergence of new, non-representational approaches to embodiment, practice and PERFORMANCE, and with the development of vitalist geographies of nature and environment, environmental perception has re-emerged as a substantive issue (see NON-REPRESENTATIONAL THEORY). A key text here has been the anthropologist Tim Ingold’s (2000) *The perception of the environment*. Ingold queries what he terms the ‘building perspective’ commonly adopted by academics examining questions of environmental perception and cognition, and imputed to those being studied. This perspective is, he argues, structured around the mistaken assumption of ‘an imagined separation between the human perceiver and the world, such that the perceiver has to reconstruct the world, in consciousness, prior to any meaningful engagement with it’ (2000, p.191).

According to Ingold, both cognitivist accounts of mental mapping and the humanistic interpretations of writers such as Tuan equally fall into this EPISEMOLOGICAL trap.

Ingold’s alternative approach to environmental perception – which he terms ‘the dwelling perspective’ – draws heavily upon the phenomenological PHILOSOPHY of Martin Heidegger and Maurice Merleau-Ponty (see PHENOMENOLOGY). Here, environmental perception is pictured as an ongoing, reciprocal, bodily process of engagement and involvement, a process in which ‘perceiver’ and ‘world’ are enrolled, and from which they are continuously emergent. This approach to environmental perception, and to self–LANDSCAPE and CULTURE-NATURE relations more generally, has begun to exert considerable influence upon cultural geographers attending to questions of perception and embodied practice.

**environmental psychology** An interdisciplinary and disparate field of study, enrolling researchers from psychology, GEOGRAPHY, anthropology, sociology, planning and design, environmental psychology examines perceptual, cognitive and embodied relationships between humans and the environment, both ‘natural’ and ‘built’. Environmental psychology is most closely and commonly associated with forms of BEHAVIOURAL GEOGRAPHY, prominent in the 1970s and 1980s (though recently renascent; see Kitchin and Blades, 2001). In contrast to the cognitivist and representational approach to human–environment relations usually adopted in this area, phenomenologically inspired forms of ecological psychology (e.g. Gibson, 1979) emphasize human (and animal)–environment relations in terms of a rolling nexus of conjoined embodied action, perception and affordance.

**environmental racism** Environmental racism includes differential exposure to harm and limiting of access to RESOURCES that are reliant on, or that reproduce forms of, racial differentiation. The term is commonly attributed to the Reverend Ben Chavis, who in 1982 was the director of the United Church of Christ’s Commission for Racial Justice when toxic chemicals were sited in Warren County, Virginia, because it was predominantly poor and black. Chavis understood this action as part of a broader institutional history of RACISM in America, and coined the term environmental racism to call attention to the official sanctioning of the life-threatening presence of poisons and pollutants in communities of colour, including those of African-Americans, Native Americans, Asian-Americans, Chicanos/Latinos and others (Chavis, 1991). This definition has been amended to include not just the actions of institutions, industries and governments, but also their failure to act, as in the case of the federal government’s lack of response to Hurricane Katrina (Sze, 2005). In addition, the current definitions hold institutions and individuals accountable whether their acts are intentional or not (Bullard, 1994). Examples include the military–industrial complex’s disproportionate exposure of Native Americans to nuclear fallout and waste dumps, creating large ‘national sacrifice zones’ in the Southwest (Kuletz, 2001). This, for example, may not be an intentional act, but is still widely considered an example of environmental racism because of
the notions of race inherent in decisions that make dumping in some sites – rural reservations, poor urban areas, immigrant communities – more ‘logical’ than dumping in upper-class white communities. Finally, still rare but growing trends in the definitions of environmental racism are both attention to environmental justice beyond the USA and attention to the ways in which racism is culturally formed or reproduced through the efforts and exclusions of the environmental movement itself (Gelobter et al., 2005).

environmental refugees A term that became used in environmental debates, starting in the 1980s, to refer to people displaced as a result of immediate environmental change, but also including those forced to move as a result of floods and the other indirect effects of global change. The category carries the rhetorical force of the word ‘refugee’, but not the international legal status of a person forced to cross a state boundary. ‘Ecological refugee’ is a synonym, but has also been used in the narrower sense of people displaced by the expansion of commercial farming and forestry operations to feed the expanding metropolitan economy of India and elsewhere.

environmental security As the cold war ended in the late 1980s, policy-makers and scholars argued that environmental change was now a major threat to international security: advocates of this ‘environmental security’ perspective argued that it required top priority from states because of the potential for serious disruptions caused by environmental refugees and likely future resource wars. Policy advocacy on these themes was part of the rationale for holding the Rio de Janeiro Earth Summit in 1992.

Sceptical scholars were unconvinced that the causal mechanisms between environmental change, disruption and conflict were proven, however frequently they were asserted as fact. Some suggested that, given the broad generality of both terms, scholarly research should be focused more narrowly on acute conflict and resources. In the 1990s, scholarly research established that there were some plausible possible links between environmental scarcities and conflict, but suggested that simple causal mechanisms were lacking (Homer-Dixon, 1999). It was also concluded that the likelihood of wars between states as a result of environmental change was small, despite numerous public pronouncements that water wars in particular were an imminent danger in many parts of the world. More generally, the literature on the causes of war also suggests that environment has rarely been a direct cause of inter-state conflict – and, indeed, might present considerable opportunities for cross-border co-operation and peace-building.

Subsequent critical work has pointed out that many of the more alarmist public discussions lack necessary analyses of either the history of resource appropriations in rural areas, or of the disruptions caused by the processes of development, and fail to adequately take these important contextual factors into account (Dalby, 2002). Critics have also argued that linking military understandings of security to environmental matters is confusing, both because military solutions are not the appropriate measures to deal with environmental difficulties and because military activities are themselves especially damaging to environments.

Geographical scholarship has recently connected insecurity with hazard vulnerability assessments and the literature on political ecology has engaged the discussion linking the global economy directly to social change. This shows that insecurity, environment and their interconnections are much more complex social phenomena than was initially assumed in the 1980s (Peluso and Watts, 2001). Despite these conceptual ambiguities, and the difficulties of establishing links between environmental change and conflict, the discussion of environmental security continues apace in policy and academic circles (Dodds and Pippard, 2005).

environmentalism The ways in which the relationships between people and their surroundings are understood and acted upon. These have varied greatly through time and within and across cultures. One, undoubtedly Western, typology for understanding some of these shifts is provided by Glacken (1967). Three environmentalisms are developed from an exhaustive history of understandings of human–environment relations. First, there is the notion that the Earth exists by design, and likely future resource wars. Policy advocacy on these themes was part of the rationale for holding the Rio de Janeiro Earth Summit in 1992.

Sceptical scholars were unconvinced that the causal mechanisms between environmental change, disruption and conflict were proven, however frequently they were asserted as fact. Graeco–Christian and Hebraic theologies, wherein creation for human purpose can lead to a legitimization of human domination over the non-human world. There are strong echoes of this form of environmentalism in contemporary thoughts and practices, which tend to be human centred (anthropocentric). The second environmentalism is underpinned by the notion that environments act as the major influence on human affairs (environmental determinism). The reductionism and sometime racist inflections of this mode of thinking have been discredited in regional geography (Livingstone, 1992), yet it is a form of environmentalism that has enjoyed a new life at a global scale and as a normative discourse. The physical resource limits of a finite planet and the capacities of global systems to adapt to human activities became major environmentalist debates and causes in the 1960s and 1980s, respectively. The third environmentalism that Glacken traces is the attempt to understand human–environment relations in more dynamic and co-evolutionary ways. It involves an understanding of the Earth and its inhabitants – including humans – as unfinished matters. Furthermore, any human change involves changes to environments and vice versa. The three environmentalisms are complex and overlap historically and culturally, but can be summarized as human mastery over nature, environmental determinism and co-evolution.

In turn, these can be roughly mapped on to contemporary inflections, including (1) anthropocentrism and technocentrism, (2) ecocentrism and (3) mutualism. O'Riordan (1976) gave particular attention to the contrast between technocentrism, which posited faith in the ability of human technical ingenuity to transcend earthly limits, and ecocentrism, which cautioned people to live within their environmentally determined conditions (see also deep ecology; population geography). The utility of the distinction can instantly be recognized in debates over food and energy technologies (genetic modifications versus organics, renewables versus nuclear energies and so on). The third stream is perhaps where most energies have been invested in geography in recent years. This is in part a reflection of the proliferation of humans and non-humans in recent centuries, making firm human–environment distinctions more difficult. Transgenic animals, genetically modified foodstuffs, holes in stratospheric ozone layers and climate change all undermine any firm distinction between people and environment, culture and nature, politics and science. Human–environment dialectics (Harvey, 1996) and feminist and post-structuralist informed reformulations of human–environment relations (Haraway, 1991c; Ingold, 2000) have produced a range of writing that attempts to pair together humans and environments through such varied endeavours as political ecology (Robbins, 2004), ecofeminism and cosmopolitics (Latour, 2004; Hinchliffe, Kearnes, Degen and Whatmore, 2005). There is a good deal of variety in these literatures, but to varying degrees they all move away from a firmly fixed or foundational view of environment and towards accounts where the mattering of environments (which include humans), their contribution to human and non-human vulnerabilities and to life chances, become central concerns. There is recognition in all these non-foundational accounts of uneven environments, of the need for environmental justice, of shifts in local and global patterns of development and consumption. Finally, in this gradual move towards a non-foundational environmentalism there are huge dangers and debates. The relatability of science as an ally to environmentalism comes under scrutiny once the fixity of environments has been unsettled, and once uncertainties and indeterminacies of scientific ways of knowing become more widely understood. The ability of science to mediate nature and act as an authority on environmental concerns has become a matter for heated debate (see risk society). Environmentalism is therefore currently in a crucial political moment as it negotiates between the uncertainties of socio-ecological dynamics and the calculations and arguments required for a shift in the ways in which humans dwell in the world.

O'Riordan (1976).

**Epidemic** A term (derived from the Greek epi-, upon + demos, people) used in the health sciences to describe the unusually high incidence of a specified illness, health behaviour or other health-related event in a given community or region; ‘unusually high’ is defined relative to the usual frequency, or expectancy, of the health event in the population under examination (Benenson, 1995). The term is often used to describe the rapid spread of an infectious disease (e.g. ‘an epidemic of measles’) and may be applied to a range of geographical scales, from small and highly localized outbreaks to global pandemic episodes. Epic events, such as the Black Death (AD 1346–53) or the Spanish influenza...
pandemic (AD 1918–19), are extreme examples from the many tens of thousands of historically recorded disease outbreaks to which the term ‘epidemic’ can properly be applied (Kohn, 1998).

epidemiology The branch of medical science that is concerned with the study of the causes, distribution and control of health-related events in a specified population. Geography and epidemiology have a long association that can be traced back to the nineteenth century and the use of disease maps to analyse the causes of epidemic events (Gould, 1985). Today, the association between geography and epidemiology finds expression in a cross-disciplinary branch of medical geography known as spatial epidemiology (Elliott and Wartenberg, 2004). Spatial epidemiologists map, analyse and model the distribution and spread of health-related conditions and their biological, environmental, behavioural and socio-economic determinants over space and through time. (See also disease, diffusion of.)

episteme A term introduced into modern thought by the French thinker Michel Foucault (1926–84) in his book Les mots et les choses, translated as The order of things (1970 [1966]). The term is based on the Greek word for knowledge or science, and for Foucault an episteme is a system of thought that conditions the particular sciences or knowledges (savoirs) that emerge at a particular time. He identifies three main epistemes: the Renaissance, the classical age and the modern. It is within an episteme that we find the criteria not just of individual pieces of knowledge, but the rules that govern the production of truth and reality as such. Foucault discounts an understanding of absolute, atemporal, aspatial knowledge, and instead analyses historically specific forms of understanding that are the conditions of possibility of knowledge (see Foucault, 1972b [1969]). In this sense, he can be understood as historicizing Kant’s work (see genealogy). Foucault rarely used the term in his later work, but introduced the notion of a dispositif (1980c), which he described as ‘a thoroughly heterogeneous ensemble consisting of discourses, institutions, architectural forms, regulatory decisions, laws, administrative measures, scientific statements, philosophical, moral and philanthropic propositions’. The notion of the episteme is now seen as ‘a specifically discursive dispositif’ (cf. discourse).

epistemology Concerned with defining knowledge and explaining how it works. While ontology attempts to account for what is in the world, epistemology asks how it is possible to know the world. Although often considered in tandem, particularly in describing the constituent elements of a body of thought, ontology and epistemology more properly should be thought of as overlapping, as there may be elements of ‘what is’ that are not knowable, and knowledge may contain ideas that do not correspond to existing things in the world. Their conceptual complications were made most explicit during the epistemological ‘turn’ in the humanities and social sciences, which was inspired by the linguistic ‘turn’ developed under the post-structuralism of Michel Foucault, Jacques Derrida and Judith Butler, among others. These connected movements rejected Platonic epistemology, which took knowledge to be innate and discoverable by profound illumination, and made it the product of circulating discourses and dispersed power relations, which were naturalized over time through their popular uptake and transformation into common notions (see hegemony). Among the political consequences of this take on knowledge was a dethroning of the notion of Truth, particularly in its a priori, universal articulation, as the lofty goal of all acts of knowing. With the new, rising wave of feminist, anti-racist and anti-colonialist perspectives and activism in and beyond the academy, the classical notion that there are absolute, knowable Truths that correspond to things in the world was increasingly critiqued as an enlightenment invention that reflected the privileged position of white, Western masculinity, the historical subjectivity holding scientific, social and political knowledge-power (Haraway, 1988; Rose, 1993). Rooted in feminism, standpoint epistemology recognizes the partiality of knowledge, but goes further by arguing that the ‘worked-for’ or ‘struggled-for’ knowledge generated by members of oppressed genders, races and classes is more likely to capture truths than the uncritical and comfortable epistemologies that evolve out of
privileged experience (Hartsock, 1983; Harding, 2004; see also *situated knowledge*).

Such concerns have made for lively debate within human geography, but epistemology is also implicit within much historical theorizing in the discipline. One of the most important threads throughout the long history of geography (see *geography, history of*) and its attendant philosophy has been an argument over the relative merits of generality and particularity. This seemingly abstract binary relates to concrete knowledge production insofar as ‘general geography’ is distinct from ‘specific geography’ (as Bernhardus Varenius, 1622–50, termed it: see *chorology*), and on that distinction rests the question of how much emphasis should be given over to the search for trans-contextual scientific laws. The answer hinges to some extent on whether geography can claim to be a mature science, one whose knowledge is objective, explanatory, rational and orderly. In the 1950s and 1960s, adherents to spatial science and regional geography fought over various aspects of these qualities (see *nomothetic* and *idiographic*), but that debate was eclipsed by humanistic geography’s outright reversal of the polarities fastened on to the *objectivity–subjectivity* opposition. Through its attention to hermeneutics, the interpretation of subjective experience and concepts such as *sense of place*, humanistic geographers reversed direction on decades of ‘scientism’ in geography, and paved the way for geographical critiques informed by feminism and post-structuralism.

Most recently, post-structuralist geography has seen a shift in epistemological emphases, from (1) a trenchant critique of knowledge claims that puts all matter into question through a constructivist epistemology to (2) a materialization of epistemology through an anti-essentialist assertion of ontology (cf. *essentialism*):

(1) Through the exploration of foreign continents, the naming of their spaces after Westerners and other Western spaces, and the mapping of those spaces in such a way that Western prejudices and power relations became inscribed upon their landscapes (see also *orientalism*), attention has long focused on the role that cartography, exploration and geography played in processes of Western colonialism during enlightenment and post-Enlightenment modernity (Mitchell, 1988; Gregory, 1994). Pervasive within the latter, mapping practice (Pickles, 2004) came to be based on a detached or ‘bird’s eye’ (Schein, 1993) *perspectivalism* that Dixon and Jones (1998) summarize as follows:

- *Cartesian perspectivalism*, ‘which lineates the world with respect to a central point’ (see also *cartesianism*);
- *ocularcentrism*, ‘which privileges vision from an elevated vantage point from which the world may be surveilled in its totality’ (see also *surveillance; vision and visuality*); and
- *the epistemology of the grid*, ‘a procedure for locating and segmenting social life so that it may be captured, measured, and interrogated’ (see *cartographic reason*).

Epistemologically, this view lent itself to a conceit of representation and to what Mitchell (1988) and Gregory (1994) call *the world as exhibition*: the power to know and control space rests in the capacity to visualize, demarcate and survey, all parts of a grid epistemology that colonizes spaces just as it dominates mainstream geography. These epistemological inquiries led many in the 1990s to debate the relative importance of *materialism* and *discourse* in the production of social space. In many cases, post-structuralism’s representational instabilities and uncertainties trumped the apparently self-evident bedrock ontologies found in materialist theories such as *marxism*.

(2) Recently, some thinkers have begun to investigate how knowledge works beyond representation. In many ways, this work harkens back to the studies of emotional and sensational connections to places highlighted under humanistic geography, though these tended to connect interiorized and subjectivized feelings to the representational idea of place. Instead, the current work draws heavily upon Gilles Deleuze’s critique of representation as a hindrance to understanding the world, which, ontologically, articulates processes of ‘pure difference’ beyond, prior or even contrary to the orders or similitude and resemblance at work in representation.
equality

A political ideal promoting the equal treatment, standing or status of people in certain respects. Equality has a close, though complex, connection to justice. While equality is a central ideal within liberal democracies (see liberalism), often enshrined as a formal right, its precise meaning and scope remain controversial. Different and often competing contexts for equality exist that variously answer the question: What is the relevant respect in which people are to be compared?

1. Administrative equality. The requirement that existing laws (see law) be administered equally to everyone. This minimal view of equality concerns the application of law, not the content. As Bakan (1997, p. 46) notes, it would be met even in a system that made explicit distinctions between people, such as apartheid, so long as laws were equally applied to all members of an oppressed group.

2. Political equality. Equality in respect to formal political rights (such as voting or running for office). This issue, of course, has proved controversial, as in the case of the struggle for the extension of the franchise to women, for example. The disenfranchisement of convicts in many US states, or the scalar politics of non-citizen voting (Varsanyi, 2005), attests to the continued relevance of this issue.

3. Formal equality. The Aristotelian principle to treat like cases as like: when two persons have equal status in relation to one relevant aspect, they must be treated equally with regard to this aspect. Thus the content of law, rather than its implementation, must not draw distinctions between people on inappropriate grounds. This, of course, begs the question: Which distinctions are legitimate? Modern liberal sensibilities forbid distinctions on the basis of gender, or race, for example. However, children and the insane are treated differently from adults of sound mind. For a law to meet the requirements of formal equality, however, requires only that it not draw illegitimate formal distinctions between people: its effects may still be unequal between people. A law that forbids all citizens from begging in public space treats all equally; however, given that only the poor beg, its effects are invidious. Moreover, interventions that seek to redress inequality through redistribution (such as social welfare or progressive taxation) compromise formal equality.

4. Substantive or social equality. The absence of ‘major disparities in people’s resources, political and social power, well-being and of exploitation and oppression’ (Bakan, 1997, p. 47). Attaining social equality is fundamental to some movements for social justice. Advocates for social equality note that people may attain formal, political and administrative equality, yet any resultant benefits are cancelled out by their manifest social inequality. In 1929, upon learning that women could, for the first time, be appointed to the Senate, the Canadian feminist Nellie McLung asked: ‘Now that we are persons [in law], I wonder if we will notice any difference?’ (http://www.abheritage.ca/famous5/leadership/legal_social_equality.html).

In other words, political equality was of limited utility while women faced the inequalities of patriarchy. Feminists have also struggled with the tension between equality and difference. For some, feminist struggle should seek to erase differences between men and women, as it is a basis for discrimination. Others argue that the differences between men and women should be acknowledged in any adjudication of rights.

As noted, the promulgation of social equality can also conflict with formal equality (as in the case of positive discrimination, for example). For some, social equality can be attained through equality of opportunity: that is, all should be allowed the same chance to compete.
for social goods and resources. Others insist on the need to attain equality of outcome or results. The parameters of social equality are, however, uncertain: Are people to attain equality in RESOURCES, material goods, well-being or capabilities, for example (Gosepath, 2005)? Equality, particularly social equality, is an important though rarely articulated principle that underlies some geographical scholarship, particularly of a critical orientation (see Smith, 2000a; see also CRITICAL GEOGRAPHY).

**Equilibrium** A state in which the forces making for change are in balance. This concept is central to NEO-CLASSICAL ECONOMICS, where a free market working perfectly is supposed to tend towards a state of equilibrium. If the forces of supply and demand for all goods and services and all FACTORS OF PRODUCTION are balanced in such a way that all supply is consumed and all demand is met, and no participant(s) in the economy can derive any further income or satisfaction from doing anything other than what is presently done, this would constitute a state of equilibrium which would be maintained until a change took place, response to which would eventually restore equilibrium.

Suppose that, in a perfectly competitive economy in equilibrium, either the extraction of coal becomes more difficult or resources are depleted, and that the coal owners put up the price of coal so as to meet the rising cost of mining. As the consumption of coal is to some extent sensitive to its price, demand for coal is reduced. The mine owners may then find that they have coal unsold and reduce its price a little to get rid of it. Eventually, the balance of forces of supply and demand will be regained by these market adjustments, at a point at which the prevailing price just clears the stocks of coal supplied. Equilibrium will have been restored. This process may, of course, involve bringing back into balance other elements of the economy disturbed by change in the coal market; for example, if there is less coal produced than before, under the new state of equilibrium this may affect employment in mining, coal delivery and so on – while if the new market price is higher, some customers may substitute other sources of fuel for coal.

In reality, an ECONOMY will be in a process of perpetual adjustment to change. Equilibrium is an ideal state that is never achieved in practice but is helpful as a concept in the understanding of a market-regulated economy (on which, see Plummer and Sheppard, 2006; Fowler, 2007). A distinction is sometimes made between general equilibrium, which relates to the entire economy, and partial equilibrium, which refers to a single market or limited set of related activities.

**Spatial equilibrium** refers to balance in a spatially disaggregated economy. Change in such a system can be spatially selective; the rise in the price of coal may be confined to a specific region, and restoration of equilibrium involves change and its repercussions working their way from place to place as well as from one market to another. The spatial version of neo-classical economics suggests the equalization of income as a feature of spatial equilibrium, since regional disparities in wages should encourage labour to move to regions where wages are highest and/or capital to move to regions where wages are lowest until equality is achieved and no advantage is to be obtained from further movement (see CONVERGENCE, REGIONAL). Just as imperfection in market mechanisms can frustrate the achievement of equilibrium in general so, in geographical space, obstacles to the free mobility of labour, capital and so on impede adjustment to wage and price differentials.

The concept of spatial equilibrium has been partly responsible for some misconceptions in regional development theory and planning practice. The terms 'equilibrium' and 'balance' have desirable connotations, and the idea of a self-regulating space-economy tending towards equalization of incomes encourages a view that market mechanisms are capable of promoting more even development if planners somehow harness them to a public purpose. However, the tendency of market economies under CAPITALISM in reality is more one of concentration and centralization, characterized by UNEVEN DEVELOPMENT and inequality of living standards, especially in the undeveloped world.
resources on their machines. A similar project, supported by the BBC, was used in 2006 to model climate change. Other developments of e-social science in the UK have been stimulated by a major research initiative in e-science, with the Economic and Social Research Council establishing a National Centre for E-Social Science at the University of Manchester (http://www.ncess.ac.uk/). There are links between e-social science and geo-computation. Geographers are involved in this work through the development of large-scale simulation models (as in microsimulation), by ‘grid-enabling’ spatial statistics (specifically geographically weighted regression) and the development of two- and three-dimensional virtual environments (cf. visualization).

**essentialism** The doctrine that holds that it is possible to distinguish between the essential and non-essential aspects of objects or phenomena. Fuss (1989, p. xi) defines it as ‘a belief in the real, true essences of things, the invariable and fixed properties which define the “whatness” of a given entity’. Essentialism is usually used as a pejorative term, but it is important to distinguish at least three different senses:

1. Epistemological essentialism is related to foundationalism, and proposes that the aim of investigation is to discover the true nature or essence of things, and to describe these by way of categorical definitions (see also epistemology). Essentialism in this sense assumes that essences are unchanging, that objects have single essences and that it is possible to gain certain knowledge of these essences. Rorty (1979) repudiates this sense of essentialism, arguing that it depends on a correspondence theory of truth that offsets reality and representation. In contrast to a picture of objects with intrinsic qualities, he affirms an ontology of contingent relations that go ‘all the way down’ (see pragmatism).

2. Philosophical critiques of essentialism have been invoked to question the validity of explanatory social theories and methodologies (see also philosophy). The argument here is that any claim that X is a cause of Y is equivalent to, or founded on, essentialism in sense (1) above. However, the argument that social phenomena have relatively stable, durable features, and that these might be ascribed some degree of causal power, is not necessarily essentialist or determinist at all. Social science methodologies and explanation tend to be fallibilistic, rather than claiming to establish absolute truth about facts or absolute foundations to knowledge.

3. A third sense of essentialism is derived from critiques of the idea that racial, ethnic, sexual or gender identities are premised on unifying, shared dimensions of experience, embodiment or social position. Criticism of essentialism is here associated with the claim that identities and norms are relational, socially constructed and historically contingent.

Anti-essentialist perspectives often run together these three senses, claiming that various harms or risks of essentialism in sense (3) are legitimized by epistemological essentialism (1) and notions of explanatory causality (2).

In human geography, essentialism became an explicit focus of debates alongside debates about postmodernism. An influential reference point was the anti-essentialist Marxism of Resnick and Wolff (1987), according to whom any causal account of social processes is inherently suspect. They propose instead a notion of overdetermination, derived from Marxist philosopher Louis Althusser, which they define as the mutual constitution of each process by all others. This anti-essentialist view of causality seems to imply that in order to be able to say anything meaningful about the relationships between processes, one must be able to provide a complete account of all existing relationships relevant to the case at hand. The anti-essentialist response to this problem is to select arbitrary entry-points, such as class or gender, into the totality of social processes, claiming a pragmatist justification for this theoretical strategy. What is being confused here is the reasonable claim that one might not want to presume in advance the existence of a necessary causal relationship with the idea that one can legitimately proffer tentative, partial, empirically grounded, and theoretically justified claims about causal relationships in the course of ongoing, fallibilistic enquiry.

If the grand philosophical claims made on behalf of anti-essentialism in geography do not stand up to serious scrutiny, then anti-essentialist perspectives have nonetheless
been a boon to forms of social constructionist and relational theorizing in the discipline. The strong political impulse behind anti-essentialism has factored in issues of gender, race, culture and the like alongside the predominant focus on economic processes and class (Gibson-Graham, 2006b [1996]). However, there has not been much explicit geographical conceptualization from this anti-essentialist perspective, despite the fact that Althusser’s original critique of essentialism in Marxism was oriented by an innovative attempt to think through the non-coincident temporalities of different processes (Althusser and Balibar, 1970, pp. 94–118). The potential herein for theorizing spatiality in a fully conjunctural and relational fashion has, however, been pursued by Massey (2005).

Discussions of essentialism in geography have become stuck in easy juxtapositions of ‘bad’ essentialism and ‘good’ social constructionism. There is a tendency to confl ate cultural essentialism with biological reductionism, causal explanation with epistemological foundationalism; and to affirm simplistic notions of constructed realities and contingent knowledge-claims (Sedgwick, 2003). Anti-essentialism presents a false choice between knowledge with certain guarantees and knowledge with nothing to back it up other than arbitrary persuasive force. In contrast, recent treatments of theories of practice suggest a reorientation of theoretical energy away from essentialist definitions of fundamental, ontological qualities, towards a greater appreciation of the ways in which concepts accrete overlapping degrees of family resemblance without ever converging around a finite number of criteria. ethics That part of philosophy concerned with the worthiness of human actions and of systems of belief regarding what people ought or ought not to do. Questions regarding our duties, obligations and responsibilities fall within the purview of ethics. While there is no universal agreement regarding which of our acts are subject to moral evaluation and argument, the actions that affect the well-being of other human beings, ourselves and/or nonhuman beings, within our midst or distant from us, are most pertinent. Ethics concerns not only the actions of individual people but social, economic and political structures and arrangements that also affect human and non-human beings. In this sense, ethics and social justice are intrinsically related to each other, if they are separable at all.

The study of ethics may be descriptive or normative, or may fall into the category of meta-ethics (see Smith, D.M., 1994a). The purpose of descriptive ethics is to understand what people actually do, and what they actually believe, with regard to rights, wrongs, duties and so on; it is not necessarily concerned with evaluating those actions and beliefs. Within normative ethics, the goal is to develop arguments or justifications for acting in particular ways and not others; normative ethics wishes to settle moral dilemmas by applying some theoretical argument to a particular case; for example, whether the US war in Iraq meets the criteria for a ‘just war’ (cf. normative theory). Meta-ethics has a broader provenance than either of these; it is the field that takes on questions pertaining to the ethical such as that; it is, it takes up the issue of what sort of territory ethics should cover. Examples of meta-ethical questions include the following: What actions call for ethical judgement? (I should exercise more frequently, but it is probably not an ethical matter if I do not.) What entities should be given moral consideration at all? (It would not be ethical to kick a dog for the fun of it, but I need not worry about kicking a soccer ball.) Can there be any moral universals? (Some people would argue that every society gives special consideration to the needy, but what counts specifically as a need may differ from one society to another.) Can moral views be objective or only subjective? (There are some philosophers who have argued there are verifiable moral facts in more or less the same way there are objective, scientific facts.)

Moral philosophers, in asking why a particular act, decision or belief is ethical, typically distinguish between consequentialist and deontological notions of ethics (Smith, D.M., 1994a). Consequentialism argues that an act (or decision or belief) must be judged against its consequences. The process is one of weighing the probable effects of one course of action as opposed to others. One makes the choice on the basis of the morally best effects. A best effect, for example, might be that the greatest good is brought to the greatest number of people: utilitarianism, in other words, is a consequentialist theory of ethics. Deontological theories of ethics evaluate actions on their own merits, independent of their consequences. They see duties and obligations as inherently good; even if a different course of
action would bring pleasure to a great many people. Thus, a deontological theorist might encourage me to give preference to the care of my own sick child over the care of other children elsewhere, even if those resources might go further in another part of the world.

Geographers’ concern with ethics and values is long-standing (Kropotkin, 1885; Sauer, 1956). To a degree, the fit between geography and ethics is an intuitive one, without necessarily saying anything about what kind of norms have emerged or in whose favour they work. The field’s attention to cultural differences between places and peoples attunes it to the fact of differing systems of values in those places, but also to the prospects for cosmopolitanism (see Popke, 2007). Likewise, geographers’ interest in interactions and flows (of people, commodities, ideas, capital) between places has made the issue of fair interactions and distributions a natural one to think about. The same could be said regarding the discipline’s focus on nature–society relationships: debates over the proper stance towards the environment, towards access to land, water and other natural resources, and towards the distribution of environmental risks and hazards are central to contemporary environmentalism. Also, the propensity of places, regions, states and other territorial arenas to be marked off from one another by boundaries – material, symbolic or both – has led to questions of who is included and who is excluded, and to what extent these determinations are ethically justifiable (Sibley, 1995; Creswell, 1996). Geography, as Sack (1997) has argued, would seem to be intrinsically morally significant and so one need not look far to see that geographers have thought so, for better and worse, for centuries (e.g. Livingstone, 1992).

What makes recent work in human geography significant is the willingness to tap moral and political thought more directly and extensively than in the past. This willingness is of a piece with the emergence of alternative – radical, feminist, queer and critical human – geographies in the past 30 years. Two reasons for greater attention to moral and political thought may be ventured. First, the social revolutions of the post–Second World War period (e.g. movements for political independence, civil rights, gender parity, peace and security, sexual liberation) came to have an enormous impact on geography, eventually leading to disciplinary moves against a geography in service to the status quo. One could say, as Harvey (1972) did, that real-world social revolutions extended into the academy, where the struggle for disciplinary space ensued (cf. Blunt and Wills, 2000). The struggle for new disciplinary spaces within geography involved delving into literatures on politics and ethics (e.g. Harvey, 1973). Second, debates among these alternative geographies have been fuelled by a similar sort of exploration, as proponents of various positions (say Marxism or feminism) have sought to make their cases to each other, or despite each other (cf. Harvey, 1992). In any event, the past thirty years has seen something of a ‘moral turn’ in the geographical literature. A particularly strong indication of this turn is the publication of surveys of moral philosophy written specifically for geographical audiences (e.g. Smith, D.M., 1994a; cf. Low and Gleeson, 1998). Smith’s efforts in particular may be viewed as a search for common ground in the struggle for greater equality globally and locally. Although his contributions are to all three fields of ethics (descriptive, normative and meta-ethics), the main thrust of his work is to see through the many differences in moral theory towards an argument (deontological) for ‘the more equal the better’ at every geographical scale. Another indication of the moral turn is the elaboration of moral arguments and concepts for purposes of advancing specific issues of concern to geographers. Examples include arguments for why the welfare of distant strangers should matter (Corbridge, 1993b; but cf. Barnett and Land, 2007); ‘care’ as a ethical–political practice, and the notion of ‘responsibility’ within a globalizing world (Brown, 2004; Massey 2004; Lawson, 2007; Popke, 2007); the application of theories of ethics to a wide range of geographical topics from place and self, to development practice and climate change (Whatmore, 1997; Proctor and Smith, 1999a; Smith, 2000a); and a burgeoning interest in the ethics of activism and research practices (Lynn and Pulido, 2003).

The moral turn in geography has been strengthened by a continuing effort to reach into new literatures. The adoption of feminist ethics and geographical reworkings of the ethical positions taken by a number of post-structuralist thinkers are good examples. Although hardly new, feminist ethics shapes the uptake of ethics in geography in important ways. Standpoint epistemologies, which are embraced by a number of strands of feminism, emphasize the embodied and therefore partial quality of knowledge (as against disembodied universal ‘truths’), including partiality.
of moral convictions – meaning that moral systems are always systems that come from somewhere, that somewhere often being a privileged, masculine sphere (e.g. the state, the church) (see also situated knowledge). At the same time, a feminist geographical perspective, because of its concern for social justice and the righting of wrongs, may argue explicitly in favour of partial, as opposed to impartial, decisions regarding distribution of scarce resources – thus the enormous influence in the geography of the 1990s of philosopher Iris Marion Young’s work on group rights (as opposed to individual rights) (Young, 1990a).

Feminist-standpoint epistemologies share with post-structuralism a scepticism towards, or even wholesale rejection of, the notion of universal truths, including the idea of universally applicable moral principles (see universalism). For this reason, the ethical and the moral are sometimes distinguished from each other, as when Cornell (1995, p. 78) states: ‘The ethical as I define it is not a system of behavioral rules, nor a system of positive standards [moralití] by which to justify disapproval of others. It is, rather, an attitude towards what is other to oneself.’ This shying away from the enunciation of rules and opting instead to cultivate a considered reflexivity (although the difference between the two can be overdrawn) is what has drawn some geographers towards thinkers such as Emmanuel Levinas, Jacques Derrida and Jean Luc Nancy. The aim is to develop an ethics that is responsible to the need for openness and difference, as against an ethics built upon foundational, universal certainties (see Popke, 2003; see also Gibson-Graham, 2003).

Whether an ethics can properly be built upon which the idea of human rights relies (see Braun, 2004a). The specific interest in post-structuralism as a resource for ethics and geography should not necessarily be construed as a radical break: it is, instead, a tool or tools for grappling with what it means to think and act in terms of relationality and in alliance with struggles for a better world. At the same time, it should be noted that there are streams of ethical thought relatively untapped by human geographers. These would include ethical systems beyond the Judeo-Christian legacy (see Esteva and Prakash, 1998), as well as the thought of ‘Western’ thinkers, such as Friedrich Nietzsche and Alain Badiou, for whom responsibility to the ‘other’ is not the objective of ethics (cf. Dewsbury, 2007).

Ethnic cleansing The forced removal of an ethnic group from a particular territory or political space by deportation, forced emigration or genocide. Examples of ethnic cleansing include the Holocaust (in which six million Jews and millions more Roma and other groups were killed), the German resettlement of western Poland during the Second World War and the attempts of the South African state to relocate blacks during apartheid. While the practice is anything but new, the term itself gained widespread use in the 1990s, when it was used to refer to Serbian attacks on Muslims in Bosnia and Albanians in Kosovo. Political geographers have shown how the idea of ethnic cleansing is an outgrowth of the ideology of nationalism, which promotes a unity between the boundaries of the state and the identity of the population (Flint and Taylor, 2007 [1985]). Ethnic cleansing thus attempts to create a territorial order based on ‘an idealized convergence of identity and space’ (Dahlman and O’ Tuathail, 2005a, p. 273). Kevin Cox (2002, p. 188) writes that ethnic cleansing ‘is a solution that arises in particular geographic situations’, such as when a minority population is dispersed within the dominant national population of the state and so cannot easily secede from the larger political unit.

Ethnic cleansing involves not only the removal of populations, but also the destruction of place and community through ‘the erasure of “other” cultural landscapes, the renaming of locales and the repopulation of the land by a new group’ (Dahlman and O’ Tuathail, 2005a, p. 273). Marcus Doel and David Clarke (1998, p. 57), in their discussion of the Holocaust, show how ethnic cleansing seeks to configure ‘social, physical, moral, and aesthetic space’ through desires for ‘purity’. Ethnic cleansing can thus be seen as a violent policing of the boundaries between the Self and the Other (see other/otherness). In their work on Bosnia-Herzegovina, Carl Dahlman and Gearoid O’ Tuathail (2005a) show how...
ethnic cleansing, with its emphasis on borders and separation, becomes a means to consolidate a political geography of security. They raise important questions about the legacy of ethnic cleansing, and what happens when the displaced attempt to return to the territories from which they were removed. AJS

ethnic democracy An ethnically differentiated form of democracy articulated by sociologist Sammy Smooha during the early 1990s (see Ethnicity). ‘Ethnic democracy’ (ED) is characterized by the allocation of equal political and civil rights on an individual level to all citizens (see Citizenship) and the parallel preservation of collective political rights of the dominant majority only. Ethnic democracy underscores the structural inequality that characterizes some formally democratic but ethnically dominated nation-states (see Democracy). The ED model maintains that the allocation of equal individual rights qualifies this regime as a democracy – even in the absence of minority collective rights – and claims that this explains its relative political stability. The ED model has sparked a lively debate both theoretically and substantively in relation to Israel/Palestine (Ghanem, 1998; Shafir and Peled, 1998; Smooha, 2002).

ethnicity Ethnicity is one of the most difficult concepts in the social sciences to define: researchers disagree on the meaning of the term; social groups differ in their expressions of ethnicity; and some theorists challenge the credibility of the concept in the first place (see Banks, 1996). The etymology of this term dates back to ancient Greece, where the word *ethnos* was used to refer to a distinct ‘people’. The word *ethnic* originally entered the English language as an adjective applied to non-Judeo-Christian peoples. The first instance of the word *ethnicity* used as a noun occurred in the early 1940s, when researchers sought to find a replacement for the word ‘race’ once it had become associated with the genocidal policies of the Nazi party (see Genocide). In contemporary usage, ethnicity is seen as both a way in which individuals define their personal identity and a type of social stratification that emerges when people form groups based on their real or perceived origins. Members of ethnic groups believe that their specific ancestry and culture mark them as different from others. As such, ethnic group formation always entails both inclusionary and exclusionary behaviour, and ethnicity is a classic example of the distinction people make between ‘us’ and ‘them’ (cf. Difference; Other/Otherness; Subject).

While much attention was given to theories of ethnicity and the nature of ethnic groups in the early twentieth century, especially in the USA (see Chicago School), interest waned in the postwar period. The Liberalism that came to dominate the intellectual climate by mid-century was predicated on a belief in the autonomy of individuals. Within the discourse of liberal individualism, the notion that people modify their actions because of their ethnic loyalties is suspect, and generally considered a fading remnant of pre-modern times. The version of Marxism that challenged liberalism in the late 1960s was equally dismissive of ethnicity, claiming that ethnic attachments were fostered by capitalists and the state in order to divide the working class (e.g. Bonacich, 1972). By the 1970s, many leading social theorists had abandoned the study of ethnicity, associating it with antiquated views of society and conservative politics. This dismissive attitude began to change in the 1980s, however, when it became clear that ethnicity was not losing its salience; on the contrary, Identity Politics were on the rise, and ethnic nationalism had become a primary force in the most violent struggles around the world, especially in the post-Cold War era – a turn of events unanticipated by liberal and Marxist scholars alike (Berkling, 2003). The fact that over 90 per cent of the world’s nation-states are poly-ethnic suggests that this type of conflict is likely to continue (see also Multiculturalism).

It is worth reflecting upon this point. Historically, the idea of a nation-state was founded on the principle of ethnic homogeneity in the form of a people or nation, which held control over a bounded territory, or state. It is debatable whether this simple correspondence between people and territory ever existed, but it is certainly clear that contemporary nation-states are characterized by multiplicity rather than mono-ethnic singularity. This has led to much discussion of the relationship between ethnicity, the nation and nationalism (e.g. Banton, 2004). As Dunn (2003b) and Amin (2004a) point out, national cultures continue to reflect outmoded assumptions of ethnic homogeneity, to the detriment of minority groups (cf. Chow, 2002). This leads to one of two prominent confusions surrounding the concept of
ethnography. Many use the term only to refer to minority groups, assuming that people in the majority are ‘normal’ while everyone else is ‘ethnic’. While this usage of the term was considered acceptable in the nineteenth century, it is no longer correct. In fact, everyone has an ethnic background, whether or not it is acknowledged. In most situations, people can only afford to be unaware of their ethnicity when they are in a privileged position (see whiteness).

A second ambiguity arises when the terms ethnicity and race are used interchangeably, or when they are seen as variants of the same classification system. For example, it is often thought that people can be divided into three or four broad racial groups and that each has a number of ethnic subdivisions (e.g. race = Caucasian, ethnicity = Italian). However, it is exceedingly difficult – many believe impossible – to discern discrete ‘races’: the genetic mixing of human populations defies such a simplistic classification system (see race). While there are obvious phenotypical and genetic differences between people, there is only one human race, a point emphatically made by the United Nations. Throughout history, though, people have been racialized by others for particular reasons. Most commentators agree that racialization is necessarily a negative process, where one group chooses to define another as morally and/or genetically inferior in order to dominate and oppress it: racialization is always an imposed category. Phenotypical features, such as skin colour or facial structure, are then interpreted as evidence that the two groups are indeed separate ‘types’ of people and are used strategically to demark the boundaries between groups (cf. apartheid). Once defined, such boundaries are extremely difficult to cross. Racialized minorities become ethnic groups when they achieve social solidarity on the basis of their distinct culture and background. Racialization therefore facilitates the development of ethnic consciousness, which may be harnessed by minorities in their struggle against discrimination (e.g. the Black Power movement of the 1960s in the USA or the Palestinian intifada), but does not necessarily lead to ethnic group formation. While external forces are important in the generation of ethnic consciousness, the most basic difference between race and ethnicity is that ethnic affiliation arises from inside a group; ethnicity is a process of self-definition.

However, ethnicity is not uniformly important to all people: the degree of ethnic identity and attachment varies strongly between and within societies. Many of the most cohesive ethnic groups have emerged after the conquest of a territory by an external power. In these cases, ethnic attachment and nationalism are powerfully fused as people affiliate to ensure the survival of their culture, religious practices and access to employment opportunities. The goal in these struggles is usually political independence. Occasionally, tensions in poly-ethnic states become so extreme that ethnic loyalty becomes the overriding social force shaping the polity. The genocide of Jews in Nazi Germany is a repugnant example of this tendency, as are the recent attempts at 'ethnic cleansing' (the forced removal of all minorities from an area) in parts of the former Yugoslavia and elsewhere. Migration is another impetus for the development of heightened ethnic consciousness. Immigrants often face hostility within the societies they enter, and form ethnic bonds and associations to increase their political credibility, economic viability and sense of social belonging. Whereas conquered groups tend to fight for independence, diasporic groups fight for the right to be included in their new societies as equal participants.

Acknowledging the variability of ethnic affiliation, theorists have long debated the causes of ethnic identity and division. Two distinct views dominate the literature: ethnicity as primordial, or absolute, versus ethnicity as constructed, as the outcome of other social processes (Jenkins, 1996; Hale, 2004). Those advocating the former see ethnicity as a basic form of affiliation that naturally emerges as people are socialized into cultures with long histories; children are born into ethnic groups and develop deep-seated attachments to them. The most extreme primordial position is taken by sociobiologists, who believe that ethnicity is a legacy of the struggle for food and shelter (Van den Berghe, 1981). In this controversial perspective, ethnic solidarity is seen as an extension of the biologically driven feelings that link individuals to their nuclear family and kin. These researchers find it difficult to explain why some people place little value on their ethnic origin and culture while others choose to express their ethnicity even when it is disadvantageous to do so.

Researchers advocating constructionist views, conversely, assert that ethnic attachments arise in specific contexts, for specific reasons. Marxists, as mentioned, often minimize the importance of ethnicity by arguing that it is a displaced form of class consciousness. In its
ETHNICITY

and educational institutions are established within different groups. According to Fredrik Barth (1969), boundaries created between groups can be resilient even when the cultural practices of the groups are no longer distinctive. In many cases, ethnic boundaries become entrenched in space, such as in the formation of ethnic neighbourhoods in cities.

Geographers have shown a long-standing interest in documenting the causes and consequences of urban ethnic segregation. Much of this work stems from the conceptualization of human ecology articulated by Robert Park and other members of the CHICAGO SCHOOL in the early twentieth century. During the 1960s, attention focused on plotting ethnic ‘ghettos’, devising ways to measure the degree of ethnic segregation (see INDICES OF SEGREGATION), and formulating PUBLIC POLICY to integrate ethnic and racialized groups across the city. By the end of the decade, a concern for ethnic residential patterns entered the mainstream of urban theory and increasingly sophisticated models of urban land use were devised. This type of work came under intense criticism after the 1970s. On the one hand, the relationship between the degree of social tolerance and residential patterns is not entirely clear; that is, a high level of segregation is not necessarily the result of discrimination, just as residential mixing does not necessarily indicate the absence of discrimination (see Peach, 1996b). On the other hand, studies of segregation have relied almost exclusively on census data. Ethnicity is defined in most censuses by respondents’ national or ‘racial’ origin, and is therefore a poor indicator of ethnic affiliation (e.g. all those of Polish descent are lumped into the same category, whether or not they identify with that cultural heritage; see Petersen, 1997). Furthermore, such classification of people perpetuates the idea that there are distinct races, and the CENSUS itself may be implicated in the racialization of minorities. Given these criticisms, the number and significance of data-intensive, quantitative studies of ethnicity declined in the 1980s. However, this type of work has been revived subsequently as the number of immigrants in European and North American cities has increased and as immigration policy has become more intensely debated.

Geographers have also devoted considerable energy studying the racialization process, especially as it impinges on people’s access to housing and the labour market (e.g. Anderson, 1991b; Jacobs, 1996). The regulatory practices of government are highlighted in
this work because immigration, housing, employment equity and other policies directly affect the way in which individuals experience discrimination and ethnic or racial difference. While this research has led to important insights, it has tended to ignore social processes operating within groups; that is, discrimination and racialization are emphasized without a corresponding interest in the agency of individuals to create ethnic consciousness and use this to struggle against domination (Leitner, 1992 – for examples of geographical work that explores the relationship between racialization and agency, see Ley, 1995; Mitchell, 1998; Gibson, Law and McKay, 2001; Kelly, 2002; also see Identity Politics). Geographers and other social scientists have also begun to examine the intersections between ethnicity and other forms of personal identity and stratification, notably Class and Gender (e.g. Anthias, 2001). Here, emphasis is placed in which each dimension of identity affects all others; for example, masculinity and femininity may well be defined and lived differently in different ethnic groups (cf. Feminist Geographies). This type of investigation is both conceptually difficult, since researchers must study many facets of experience and social structure simultaneously, and controversial, since it destabilizes traditional definitions of class and gender. ethnoburb A term popularized by Li (1998) to describe the residential patterns of Asian migrants to Australian, Canadian, New Zealand and US cities in recent decades. Traditional models of ethnic residential patterns (following the Chicago School) link them to processes of economic, social and cultural Assimilation, whereby over time ethnic groups lose their separate Identity and merge into the wider population, at the same time becoming dispersed through the urban fabric away from their original concentrations in Ghetto-like areas. Contemporary Multiculturalism policies, on the other hand, promote economic integration alongside cultural Difference, so that ethnic group members retain their separateness.

Ethnoburbs reflect this changed situation, involving migrant groups comprising more skilled and wealthier populations than was the case in the first half of the twentieth century – alongside continued streams of low-status immigrants (such as Hispanics to the USA and Pacific Islanders to New Zealand). These new – predominantly Asian – groups tend to cluster in suburban areas, but rarely dominate the local population, although perhaps being more visible in the Landscape (because of their housing and retail businesses) than their numbers suggest. And, Li argues, such concentrations may be much more permanent elements of the residential matrix than the enclaves associated with earlier migrant streams. RJ

ethnocentrism Most cultures and peoples have historically inscribed themselves at the centre of the world. ‘Ethnocentrism’ refers to the practice of taking one’s own subject position as the central reference point in relation to which all others can be arrayed with regard to their difference (see also Others/Othering). Like anthropologists and sociologists, geographers have worked to uncover and counter the ethnocentric Universalism implicit within much geographical practice and analysis (Godlewska and Smith, 1994; Agnew, 1998) (cf. Anglocentrism; Eurocentrism).

ethnocracy A type of regime conceptualized by geographer Oren Yiftachel during the mid-1990s, in which a dominant ethno-national group appropriates the State Apparatus to expand and deepen its control over contested territory and power structures (Yiftachel and Ghanem, 2004). Ethnocracies typically represent themselves as democracies (see Ethnic Democracy), but are characterized by high levels of unequal segregation between rival ethnic nations and by structural inequalities between ethno-classes within each nation. Driven by a hegemonic project of ethnicization and internal colonization, ethnocracies are neither democratic nor authoritarian. They can be found in states such as Sri Lanka, Latvia, Israel and Sudan. Ethnocracies typically lack equal Citizenship, separation of religion and state, or proportional minority representation and Rights, and have suffered chronic political instability (Kedar, 2003).

ethnography From the Greek etnos (the nation) and graphe (writing), ethnography is
most closely associated with the discipline of sociocultural anthropology, and with participant observation and long-term, in-depth engagement with specific communities or societies. It refers to both a set of research methods and to the written product.

Ethnography has often come under attack for its role in British colonial efforts to produce detailed knowledges about native populations in order to govern and control them. Yet the meanings, practices and uses of ethnography are multiple and contentious, and have shifted radically over time. In recent years, sociologists, historians and geographers have joined with anthropologists to focus on how ethnography can be used to forge politically enabling understandings of processes glossed by the term ‘globalization’ and to illuminate the possibilities for social change. Relational conceptions of the production of space and scale associated with Henri Lefebvre (1991b) are becoming increasingly important in efforts to construct a project of critical ethnography.

During the 1980s, ethnography came under sharp attack from within anthropology. In Writing culture (1986), Clifford, Marcus and others challenged presumptions of ‘ethnographic authority’, and propelled what has been termed the reflexive turn (see reflexivity). Instead of simply discovering or reflecting culture, they argued, ethnographers actually write or produce it. Since the 1980s there have also been a number of feminist critiques of ethnography, some of them simultaneously critical of the sort of experimental writing and textual strategies promoted by authors of the reflexive turn (e.g. Behar and Gordon, 1995). In another set of anthropological critiques, Appadurai (1988) and others condemned traditional ethnographies through which mobile anthropologists produce knowledge that incarcerates ‘natives’ in bounded localities, and map essentialized cultures onto bounded territories. He insisted on ethnography that is not so resolutely localizing, while others proposed the metaphor of travel as a means of escape for the ethnographer from the ‘incarceration of the local’ and the supposed stasis of space.

By the 1990s, growing numbers of anthropologists were calling for critical understandings of space, place and culture that went beyond metaphors of travel, flows and territorialization. In Culture, power, place: explorations in critical anthropology, Gupta and Ferguson pointed to the necessity of ‘exploring the processes of production of difference in a world of culturally, socially and economically interconnected and interdependent spaces’ (1997, p. 43), and the ethnographic essays in their volume exemplify that argument. In Ethnography through thick and thin (1998), Marcus sought to update his earlier critique of cultural anthropology with a call for multisited ethnography. The bringing together of ethnography and history by the Comaroffs (1992), Cooper and Stoler (1997b) and others was also an important development in the 1990s. Relational understandings of space and place are implicit in some of this work.

From within sociology, a significant strand of scholarship that is moving towards critical understandings of spatiality is the project of global ethnography spearheaded by Michael Burawoy and his students (2000). While ethnography has generally occupied a marginal position in sociology, it formed the basis of the Chicago School of urban sociology that goes back to the 1920s. A partial descendant of the Chicago School, Burawoy has shifted sociological deployments of ethnography in radically new directions. In their ‘Manifesto’ that launched the journal Ethnography, Willis and Trondman (2000) echo Burawoy’s emphasis on theory as a ‘precursor, medium and outcome of ethnographic study and writing’. They propose time (theoretically informed methodology for ethnography) as an appropriate acronym, as well as being relevant in a non-acronym sense.

These moves to redefine ethnography are further enriched by more explicit attention to a conception of space (or space–time) and scale as actively produced through situated, embodied material practices and their associated discourses and power relations (Lefebvre, 1991b). For example, there remains a widespread tendency to conceive of ‘place’ as concrete, and ‘space’ as abstract – in other words, a notion of place as space made meaningful. A Lefebvrian understanding of the production of space decisively rejects this distinction. Instead, space and place are both conceived in terms of embodied practices and processes of production that are simultaneously material and discursive. From this perspective, place is most usefully understood as nodal points of connection in wider networks of socially produced space – what Massey (1994b) calls an extroverted sense of place. If spatiality is conceived in terms of space–time and formed through social relations and interactions at all scales, then place can be seen as neither a bounded enclosure nor the site of meaning-making, but rather as ‘a subset of
the interactions which constitute [social] space, a local articulation within a wider whole’ (Massey, 1994b, p. 4). Places are always formed through relations with wider arenas and other places; boundaries are always socially constructed and contested; and the specificity of a place – however defined – arises from the particularity of interrelations with what lies beyond it, that come into conjuncture in specific ways.

A conception of place as nodal points of connection in socially produced space enables a non-positivist (see positivism) understanding of generality. In this conception, particularities or specificities arise through interrelations between objects, events, places and identities; and it is through clarifying how these relations are produced and changed in practice that close study of a particular part can generate broader claims and understandings. Such an approach underscores the fallacies inherent in notions that concrete studies deal with what is local and particular, whereas abstract theory encompasses general (or global) processes that transcend particular places. This conflation of ‘the local’ with ‘the concrete’ and ‘the global’ with ‘the abstract’ (see local-global relations) confuses geographical scale with processes of abstraction in thought (Sayer, 1991).

Critical conceptions of spatiality are central to relational comparison – a strategy that differs fundamentally from one that deploys ideal types, or that posits different ‘cases’ as local variants of a more general phenomenon (Hart, 2006). Instead of comparing pre-existing objects, events, places or identities, the focus is on how they are constituted in relation to one another through power-laden practices in the multiple, interconnected arenas of everyday life. Ethnographic studies that clarify these connections and mutual processes of constitution – as well as slippages, openings and contradictions – help to generate new understandings of the possibilities for social change.

ethnomethodology An approach to studying social order and practical reason that discloses how people or ‘members’ produce everyday situations, deploying concepts that neither ironicize nor stipulate those found in situ. The concern is the routine practices through which situations ‘occasion’ said members, and vice versa, thus catching the self-rendering and self-describing of these situations as exactly what they are in the immediate flow of their conduct. Attention alights on the ‘how’ of this conduct – just how the people involved do what they do – and on recovering both the ‘skills’ exhibited by members and the situated, local, changeable ‘orders’ whose ‘rules’ they knowingly follow. Ethnomethodologists resist importing theoretical constructs that derive from ‘elsewhere’ or are specified at a level of abstraction removed from the situation in question. They retain a sustained commitment to the empirical, but reject the taken-for-grantedness of ‘social facts’ typifying empiricist or positivist social science, preferring instead to ascertain how a supposed ‘social fact’ has come about, become recognized and then entered the situated practical knowledge of people in the grain of their everyday lives. Central here is the reflexivity of the researcher, not so much through continually interrogating their own positionality, but through gauging the ‘how’ of their own conduct; that is, how they do what they do themselves when researching as a practical activity.

Ethnomethodology has intellectual roots in Alfred Schutz’s constitutive phenomenology and Erving Goffman’s micro-sociology of the everyday, both of which have figured in versions of human geography post-1970. The key figures here, though, are: Harold Garfinkel (e.g. 1967), who declared that the researcher must learn from members ‘what their affairs consist of as locally produced, locally occasioned, and locally ordered, locally described, locally questionable, counted, recorded, observable phenomena of order’ (Garfinkel and Weider, 1992, p. 186); and Harvey Sacks (e.g. 1992), who developed conversation analysis (CA), taking seriously the ‘analysis’ that we all do while conversing as well as the timing, spacing and indexicality (the significance of immediate contexts to the progress) of any conversation. There has been no concerted attempt to create an ethnomethodological geography, although ethnomethodological ‘policies’ have filtered into the discipline through ethnography and also brushes with the likes of symbolic interactionism, actor-network theory (ANT) and non-representational theory (NRT).

In various studies – on mobile phone use in cars, everyday life in coffee-houses, practices with pets – Laurier (1998, 2004) has worked between geography and ethnmethodology, highlighting how such a position differs from ‘the requirements of the performance of “doing competent cultural geography”’ (Laurier, 2001, p. 486). Unlike NRT’s
wariness of spoken communication, he follows the impetus of CA in foregrounding ‘talk’ as social action, within which members undertake ‘representational work’ as it occurs in the immediacy of the here-and-now. He recognizes the objection that ethnomethodology appears not to tackle what theorists take as larger, more enduring ‘social structures’, responding on the one hand (with ANT) that such structures cannot just be the fragile accomplishment of countless interlinking peoples, conducts and situations, and on the other by seeking commonalities with the ‘archaeological’ method pioneered by Michel Foucault when dealing with the (seemingly grander) operations of DISCOURSE and POWER (Laurier and Philo, 2004).

**Euclidean space** The metric space defined by the geometric system devised by the Greek mathematician Euclid of Alexandria. Euclidean space (sometimes called Cartesian space; see CARTESIANISM) is the space typically presumed in everyday discussion and in more formal accounts of distance, interaction or spatial distribution in HUMAN GEOGRAPHY. Euclidean space is based on five axioms:

- Any two points can be joined by a straight line.
- Any straight-line segment can be extended indefinitely in a straight line.
- Given any straight-line segment, a circle can be drawn having the segment as radius and one endpoint as centre.
- All right angles are congruent.
- The parallel postulate. If two lines intersect a third in such a way that the sum of the inner angles on one side is less than two right angles, then the two lines inevitably must intersect each other on that side if extended far enough.

From the 1970s, geographers explored both the power and the limits of Euclidean space for mapping the Earth (see CARTOGRAPHY), recognizing that the surface of the GLOBE is not Euclidean but a two-dimensional surface of constant positive curvature. Spatial analytical modelling often presupposes Euclidean space, although there have been some experiments with non-Euclidean spaces, such as Riemannian and Lobachevskian geometries and multi-dimensional spaces (see also SPATIAL SCIENCE).

Euclidean space has long been treated as absolute and homogeneous, properties that for Lefebvre (1991b) guarantee its social and political utility. This utility emerges first as ‘NATURE’s space’ and later as all of social life is reduced to Euclidean space. The result is a double reduction of complex three-dimensional realities to a two-dimensional space, and to the space of two-dimensional objects that can be ‘naively’ mapped or represented. At this point, the spaces of lived experience are normalized and seen as reducible to abstract and transparent spaces: the god-trick has rendered the world as something to be looked at from a distance, as a world-as-picture or world as exhibition, where complex social and natural worlds have become intelligible to the eye, to be read and represented (Heidegger, 1962 [1927]; see also EPistemology; proDuction of space).

**Eurocentrism** A world-view that places ‘Europe’ at the centre of human history, social analysis and political practice. These three spheres are closely connected, and revolve around the constitution of ‘Europe’ as subject and object of enquiry, as architect and arbiter of method, and as exemplar and engineer of progress. Thus:

1. ‘Europe’ is placed at the centre of human history through the assumption that it provides the model and master-narrative of world history: that its histories (and geographies) are the norm and the rule, from which others learn or deviate.

2. ‘Europe’ is placed at the centre of social analysis through the assumption that its theoretical formulations and methods of analysis provide the most powerful resources for all explanation and interpretation.

3. ‘Europe’ is placed at the centre of political practice through the assumption that its cultural and political systems act as the bearers of a universal Reason that maps out the ideal course of all human history (see ENLIGHTENMENT).

**EUROPE** appears in scare-quotes throughout the preceding paragraph to draw attention to its cultural construction. The very idea of ‘Europe’ has a long and far from unitary history. Eurocentrism has a long history (or rather historical geography) too, through which it has been so closely entwined with the projects of COLONIALISM and IMPERIALISM (Blaut, 1993) that it cannot sensibly be confined to the CONTINENT of Europe. In the course of those discursive expansions, ‘Europe’ has turned into ‘the WEST’ (cf. ORIENTALISM), which
has more recently been turned into the global ‘NORTH’ (cf. SOUTH). Each one of these transitions has been freighted with its own cultural and political baggage, but their general burden is clear. ‘Eurocentrism is not merely the ETHNOCENTRISM of people located in the West’, Dhareshwar (1990, p. 235) notes, but rather ‘permeates the cultural apparatus in which we participate’: it is a global IDEOLOGY. It follows from these characterizations that it is possible to study Europe without being Eurocentric, and that it is equally possible to study non-European societies in thoroughly Eurocentric ways.

Geography has a particular and a general interest in Eurocentrism. Historians of the modern discipline have argued that it is a constitutively ‘European science’ (Stoddart, 1986). Critics have objected that this erases the contributions of other geographical traditions (Arab, Chinese and Indian among them) and that GEOGRAPHY in its modern, transnational and hegemonic forms (see HEGEMONY) is more accurately described as a ‘Eurocentric science’ (Gregory, 1994; see also Sidaway, 1997). Work in the history of geography (see GEOGRAPHY, HISTORY OF) has drawn attention to these issues through an interrogation of geography’s complicity in the adventures of colonialism and imperialism and, in particular, of the reciprocities between the intellectual formation of the discipline and the political trajectory of European expansion, exploitation and dispossession (Driver, 1992b). During the nineteenth and early twentieth centuries, the discipline invested heavily in activities that had considerable instrumental value (some historians have suggested that it was precisely these practical contributions that helped secure the formal incorporation of the modern discipline within the Western academy). Its strategic contributions included mapping and surveying other territories, compiling RESOURCE inventories, and producing IMAGINATIVE GEOGRAPHIES of other peoples and places. These investments contributed to the formation of the modern discipline as a ‘white mythology’ that: (a) postulated a racially unmarked subject-position as the condition of objective truth and scientific discourse; (b) effaced alternative subject-positions; and (c) appropriated other forms of knowledge – all three gestures are diagnostics of Eurocentrism (Barnett, 1998; see also WHITENESS).

In the course of the twentieth century, Eurocentrism bled into what Peet (2005) describes as the ‘even more virulent geo-cultural form’ of AMERICENTRISM. There are crucial differences as well as affinities between the two (Slater, 2004, pp. 13–16), but both cultural formations have underwritten and been propelled by military force and capitalist GLOBALIZATION. Their conjunction was registered within the modern discipline by the designation of a singular ‘Anglo-American geography’ in the 1960s and 1970s, but this was a double exclusion: apart from some key contributions from German and Swedish writers, non-Anglophone European geographers were marginalized (Eurocentrism had contracted to an ANGLOCENTRISM), and classical SPATIAL SCIENCE offered a series of supposedly general MODELS that were in fact predicated on specifically European and American cases (Christaller’s Germany, Burgess’s Chicago) (cf. McGee, 1995). Since then, however, while the intellectual corpus of ‘Anglo-American geography’ has become increasingly fractured – here too there are differences as well as affinities – Slater (1992) could still argue that much of it continued to rely on a EURO-AMERICANISM that projected its own situations as ‘lineages of universalism’. Slater claimed that the dependence of an ostensibly CRITICAL HUMAN GEOGRAPHY on European and American traditions of CRITICAL THEORY, HISTORICAL MATERIALISM and POSTMODERNISM (the list could now be extended: FEMINIST GEOGRAPHY and POST-STRUCTURALISM have been exercised by the same questions) tacitly licensed assumptions of ‘universal applicability’ that concealed ‘a particularity based to a large extent on the specific experiences of the USA and the UK’. Geographies written under the sign of POST-COLONIALISM have been directly interested in these issues – in the need to ‘provincialize’ the assumptions of Euro-American geography, to attend to other voices and to ‘learn from other regions’ – but they also often draw directly on European high theory, and Slater (2004) has demonstrated that they have much to learn from other politico-intellectual traditions too (cf. TRICONTINENTALISM).

Geography is scarcely alone in these predicaments, and in the sense of DISCOURSE rather than discipline it has a more general involvement in Eurocentrism. Gregory (1998) has drawn attention to four conceptual strategies – ‘geo-graphs’ – that entered directly into the formation of a colonial MODERNITY:

1. **Absolutizing time and space**: the construction of concepts through which European metrics and meanings of history and geography were taken to be natural and inviolable, as marking the centre
around which other histories and other geographies were to be organized (cf. Young, 1990b).

(2) **Exhibiting the world**: the production of a space within which particular objects were made visible in particular ways, and by means of which particular claims to knowledge made by viewing subjects were negotiated and legitimized.

(3) **Normalizing the subject**: the production of spaces of inclusion and exclusion that treated the subject-position of the white, middle-class, heterosexual male as the norm.

(4) **Abstracting culture and nature**: the production of ‘nature’ as a realm separate from ‘culture’, in which European *culture* had made *nature* yield its secrets and its resources, and in which temperate nature was ‘normal nature’ (cf. Blaut, 1999).

This argumentation-sketch is more than an exercise in historical reconstruction. ‘In elucidating the conceptual orders of Eurocentrism,’ Gregory argues, ‘it becomes much more difficult to assume that we have left such predicaments behind, and much more likely that we will be forced to recognise that Eurocentrism and its geo-graphs continue to invest our geographies with their troubling meanings.’

**Europe, idea of**  The region that we now call Europe is the western part of the Eurasian landmass. Europe has no clearly defined borders, particularly in the east, but the region’s history can be read as an ongoing attempt to define what it means to be European and to fix that identity on the map (Heffernan, 1998). This process has generated a series of non-European ‘others’, against whom Europeans have defined themselves.

The term ‘Europe’ is derived from *Europa*, a female character in Greek mythology. The word had no geographical meaning for the Classical civilizations centred on the Middle East and the Mediterranean basin, and little significance in the Roman Empire. It is absent from the Bible, but was used alongside ‘Christendom’ in the early medieval period to describe the area where Christianity prevailed and where a literate elite shared a common Latin language. On medieval world maps, Europe was depicted as a small, internally undifferentiated area, vulnerable to incursion from the Islamic regions of Asia and Africa, which were Europe’s first constituting ‘others’ (Hay, 1968; Wilson and van den Dussen, 1993).

The expansion of Europe into the Americas from the late fifteenth century was both a cause and a consequence of the intellectual and technological changes associated with the European Renaissance, and provoked a major reassessment of Europe’s place in a world still seen as divinely created (Wintle, 1999, 2008). The opening of the Americas also generated a new economic system based on long-distance Atlantic trade and a new political system based on competitive European nation-states, whose interests clashed repeatedly in Europe and the Americas during the collapse in the fragile unity of the Christian church following the Reformation. As ‘Christendom’ disintegrated into a complex mosaic of Catholic and Protestant communities in the Old and the New Worlds, the word ‘Europe’ lost its religious connotation. In the wake of the Treaties of Westphalia (1648), which ended the European Wars of Religion, Europe was defined as the region in which a ‘balance of power’ might operate between rival nation-states by mutual consent (Pagden, 2002).

The geographical limits of this arrangement were famously outlined in the Duc de Sully’s mid-seventeenth-century Grand Design for European unity. For Sully, the Ottoman Empire had no part in the ‘concert of Europe’, because international agreements ultimately rested on Christian values. Christian Russia was also excluded, because the Russian people were deemed essentially Asiatic and hence culturally inferior. Europe now had two constituting ‘others’, a traditional religious enemy in the Islamic south and a new cultural enemy in the Asiatic east. Sully’s cultural definition of Europe highlights a fundamental irony at the heart of the European debate. At the very moment when Europe was defined politically in the most enlightened terms as an area where permanent peace might be established by international agreement, it was also defined geographically to exclude the peoples of other regions who were deemed unworthy on cultural or civilizational grounds (Heater, 1992; Wolff, 1994; Neumann, 1996: see also Civilization; Nomos).

The legitimacy of imposing geographical limits on supposedly universal Human Rights was hotly debated during the eighteenth-century Enlightenment, but the freedom educated Europeans (including those who had settled beyond Europe) claimed for themselves in their hard-won battles against the
tyranny of unelected rulers in Europe was never extended to the native peoples of Asia, Africa and the Americas. The fate of these people was to be decided by the colonizing Europeans. The values of enlightened democracy shone brightly in eighteenth-century Europe and the newly independent European North America, partly because the rest of the world had been simultaneously darkened.

During the nineteenth century, the high point of European imperialism, the cultural criteria used to define Europe were recast yet again, this time in racial and biological terms, inspired by the prevalent theories of social darwinism and environmental determinism. The European peoples were deemed not merely to have acquired a superior level of civilization but, rather, to possess an inherent racial superiority, a consequence of their uniquely benevolent physical environment (see race). This both explained and justified the European domination of the world.

As the last remaining uncolonized regions of the world gradually diminished, so the tensions between different European nations increased, unleashing a more or less continuous period of intra-European warfare from 1914 to 1945. This ended with the attempt by the Nazi authorities in Germany to eradicate long-established European communities, notably the Jews, in the name of a racially ‘pure’ Europe. If a ‘dark continent’ has ever existed, it was surely Europe between 1914 and 1945 (Mazower, 1998: see also genocide, holocaust).

Europe was divided in 1945, the western and eastern parts of the region dominated by the opposing military superpowers of the USA and the Soviet Union, respectively. New measures to foster economic integration developed on both sides during the cold war from the 1950s to 1980s, most successfully through the European Economic Community (EEC) and its successor the European Community (EC), which eventually encompassed most of the national economies of western Europe. This generated remarkable economic success but little additional discussion about the essential meaning of Europe, mainly because the region previously regarded as Europe seemed permanently divided. The word ‘Europe’ had little currency in eastern Europe in this period and acquired only a limited economic meaning in western Europe (Jutud, 1996, 2005).

The realignment of central and eastern Europe after the collapse of the Soviet Union and the reunification of Germany has been achieved with remarkable speed, and amid continuing economic success. The enlarged European Union (EU) now includes 27 countries with a combined population approaching 500 million. Twelve countries, with a total population in excess of 300 million, share a single currency (the euro), established in 1999. These seismic developments have begun to generate new reflections on the fundamental idea of Europe, but it remains to be seen whether an enlarged Europe will develop a distinctive identity in the twenty-first century and emerge as a political and economic counterbalance to the USA. Whether the new Europe needs such a ‘nation-like’ identity is a moot point, however, for it might more usefully be defined as a set of values and aspirations that consciously reject the exclusive geographies of the past (Delanty, 1995, 2005a; Amin 2004a; Levy, Pensky and Torpey, 2005; Beck and Grande, 2007; Heffernan, 2007: see also cosmopolitanism).
processes and practices, one whose provenance lies between STRUCTURALISM and PHENOMENOLOGY, and one that raises lived experience to the level of a critical concept (Kaplan and Ross, 1987). The subject crosses disciplinary boundaries and indeed brings them into question, as suggested by references to an emerging ‘everyday life studies’ (Highmore, 2002). It has also found prominence in recent arts and cultural practice. Important for understanding the spaces and places of everyday life have been theorists such as Walter Benjamin, Michel de Certeau and Lefebvre, whose belated translation into English has been a significant spur to Anglophone scholarship. But geographical interest in the subject is long-standing, and other significant approaches in recent decades are associated with HUMANISTIC GEOGRAPHY and FEMINIST GEOGRAPHY.

Recovering everyday geographical experiences against their erasure within SPATIAL SCIENCE concerned many humanistic geographers who, influenced by phenomenology and writings by Edmund Husserl and Maurice Merleau-Ponty, turned attention to the LIFEWORLD and to emotional and subjective encounters with and attachments to places, often privileging notions of HOME. In the process, they stressed the work involved in interpreting geographies of the everyday, including the need for self-REFLEXIVITY. But while humanistic geographers debated the necessity for philosophical rigour, with some preferring a looser constitutive phenomenology derived from Alfred Schutz to concentrate on how the lifeworlds of ordinary social groups are intersubjectively constituted in particular places, and with others distancing themselves from THEORY to embrace ‘experience’ as such, feminists and Marxists criticized their neglect of the POWER relations that structure everyday experiences of PLACES, including within the home, and hence their inability to advance deeper critiques of exploitation and oppression. It is with that in mind that many feminist geographers have focused on ordinary activities and repetitive social interactions, considering how they are bound into structures that discriminate against women and reinforce gender hierarchies (cf. STRUCTURATION THEORY).

According to Susan Hanson (1992), finding significance in the everyday is a core analytic tradition shared by FEMINISM and geography. She shows how this focus can undermine the common opposition between home and work, for example, by demonstrating their interconnections at the level of everyday lives and practices with important implications for understanding local LABOUR MARKETS and gender divisions of work in both. To bring daily activities into focus, many feminists have employed TIME-GEOGRAPHY, which was developed by Torsten Hägerstrand and colleagues at the University of Lund during the 1960s and 1970s, in a context in which ideas about everyday life had been central to Swedish welfare and urban planning. Plotting women’s daily space–time paths enabled insights into the role of GENDER relations in the temporal and spatial structuring of social action, and hence into ‘the reproduction of PATRIARCHY in the banal activities of everyday life’ (Rose, 1993, p. 25). Gillian Rose nevertheless criticizes time-geography’s universal depiction of space and its claim to exhaustiveness, which she depicts as MASULINIST, along with its inability to address differential embodiment, emotion and passion. Her concerns relate to those frequently raised more generally about the appropriateness or otherwise of different ways of apprehending the everyday, the actuality of which always exceeds attempts at capture.

Feminist interest in the geographies of the everyday is also often connected with debates about SOCIAL REPRODUCTION, which for Cindi Katz (2004, p. x) is ‘as much the fleshy, messy, and indeterminate stuff of everyday life as it is a set of structured practices that unfold in DIALECTICAL relation to production, with which it is mutually constitutive and in tension’. Yet she insists that social reproduction must be understood as a critical practice marked by the refusal to see the process as inevitable or natural, and by attentiveness to resilience as well as to possibilities of reworking, resistance and even revolution. In that sense, Katz likens it to Lefebvre’s influential double-sided concept of everyday life, which he developed over many decades and which is central to his writings on URBANISM and THE PRODUCTION OF SPACE. On the one hand, Lefebvre used the terms ‘the everyday’ and ‘everydayness’ critically as referring to the entry of daily life into MODERNITY, as he developed Marx’s account of ALIENATION to address how everyday life has been colonized by the COMMODITY and the STATE through the imposition of an abstract space. But he also sought redemptive possibilities within the everyday, arguing that it harbours traces of more authentic living as well as the potential for radical change and for the production of other differential spaces. It is therefore a key terrain of struggle.

Challenges to characterizations of everyday life as self-evident, immutable and universal
have also come through place-specific studies of changing everyday worlds and language under conditions of modernity that are attentive to multiple practices and power relations (Pred, 1990), and cross-cultural enquiries into everydayness and its conceptualization as a means of figuring cultural experiences of modernity and capitalist modernisation (Harootunian, 2000). Lefebvre’s own critique needs situating within a French tradition of everyday life theorizing that developed especially during the 1960s and 1970s in the context of rapid modernization and processes of decolonization, and that included de Certeau, Roland Barthes, Georges Perec and the situationists, as well as the surrealists before them. This tradition’s influence is apparent in much current human geography, where it has been taken up alongside phenomenological and feminist writings to inform studies of practice, performance and embodiment as well as narrative and rhythm in the construction of space and time (Simonsen, 2004; see also body). A concern with drawing out the extraordinary within the ordinary and what Lefebvre called ‘the minor magic in everyday life’ has also occupied many geographers, including those influenced by non-representational theory, who have sought new means of noticing the practical knowledge, skilled improvisation and intuition involved in ‘the elusive, phantasmic, emergent and often only just there fabric of everyday life’ (Thrift, 2000d, p. 407). While much work on everyday life has emphasized the resistant and subversive tactics of ordinary people, drawing especially on de Certeau (1984) in the process, some writers are seeking to re-evaluate repetition, habit, familiarity and the non-intentional aspects of the corporeal as demanding fuller attention in their own right. For others, it is the utopian impulse concerned not simply with describing everyday life but also with transforming it for the better that remains so compelling (see also utopia). The approach began in health care (the term ‘evidence-based medicine’ first appeared in 1992) and has become a world-wide movement in the Cochrane Collaboration (http://www.cochrane.org/index0.htm), which aims to provide the ‘reliable source of information in health care’. Particular emphasis is placed on randomized trials in which the recipient is randomized to the new intervention (cf. sampling): the epidemiologist Archie Cochrane had famously argued that researchers should ‘randomise until it hurts’. The approach has been extended into the social arena with the Campbell Collaboration (http://www.campbellcollaboration.org/), named after the distinguished social science methodologist Donald T. Campbell. This aims to answer the question ‘What harms, what helps, based on what evidence?’ and a Centre for Neighbourhood Research was created as part of the UK Network for Evidence-based Policy and Practice (http://www.evidencenetwork.org/).

The orthodox approach to evidence-based policy is based on a systematic review finding all the relevant studies including grey literature, weeding these for methodological flaws and inconsistencies, ranking the evidence so that the greatest reliance is placed on well-designed randomized trials, and then combining valid evidence quantitatively in a meta-analysis to provide the ‘weight of evidence’ supporting best practice. A heterodox view is provided by Ray Pawson (2006), who argues for what he terms ‘realist synthesis’ that stresses generative mechanisms and causal contingency, so that data analysis aims to find ‘what works for whom in what circumstances’ (cf. pragmatism). Consequently, there is not a single ‘best buy’ for all situations, but a tailored, transferable theory that works in these respects, for these subjects, in these kinds of contexts.

exception, space of A topological space produced when a sovereign power invokes the law in order to suspend the law. Its modern formulation is closely associated with right-wing political philosopher Carl Schmitt (1888–1985), who declared: ‘Sovereign is he who decides the exception.’ Italian political philosopher Giorgio Agamben radicalized Schmitt’s work to argue that it is the act of deciding the exception that defines the sovereign: that this is the ground and origin of
sovereign power (rather than vice versa) (Agamben, 1998). This crucial decision – in the original German sense of ‘a cut in life’ – is at once performative and paradoxical. It is PERFORMATIVE because it draws a boundary between politically qualified life and merely existent life wilfully exposed and abandoned to violence and death (‘BARE LIFE’) that has the most acutely material consequences. And it is paradoxical, and all forms of life are thereby made precarious, because the boundary is mobile and indistinct (cf. ZONE OF INDISTINCTION).

Agamben writes about both a ‘state’ of exception and a ‘space’ of exception, and his argument bears on SPATIALITY in at least three ways.

1. Agamben uses Set Theory to argue that the exception – from the Latin ex-capere, which literally means that which is ‘taken outside’ – is a paradoxical spacing because it ‘cannot be included in the whole of which it is a member and cannot be a member of the whole in which it is always already included’ (1998, p. 25). This limit-figure must be captured topologically (see TOPOLOGY), he concludes, because only a twisted CARTOGRAPHY of POWER is capable of folding such propriety (the invocation of the law) into such perversity (the suspension of the law).

2. Many analyses of the space of exception focus on enclosed sites (the Nazi concentration camp at Auschwitz, IMMIGRATION and REFUGEE detention centres, and the US war prison at Guantánamo Bay, Cuba: see, e.g., Gregory, 2006b) or territorialized configurations of power (the shattered fragments of occupied Palestine: see, e.g., Gregory, 2004b), but by their very nature, spaces of exception may be much more indeterminate than these exemplary spatial formations imply.

3. The state of exception is typically associated with the declaration of a national emergency and the imposition of martial law by a STATE, and Agamben argues that the growth of a national security state and the intensification of its sovereign powers through the GLOBALIZATION of the ‘war on terror’ has turned the state of exception into a new PARADIGM of late modern government (Agamben, 2005, pp. 1–31: cf. GOVERNMENTALITY). But these national framings are also affected by transnational GEOPOLITICS and geo-economics, and by international law (Gregory, 2007).

exceptionalism The view that ‘geography is quite different from all the other sciences, methodologically unique’ (Schaefer, 1953, p. 231). The term was coined by Fred K. Schaefer to disparage this, the dominant conception of American GEOGRAPHY codified by Hartshorne (1939) in his enormously influential prospectus for The nature of geography. Instead, Schaefer argued that geography was just like every other science, sharing a methodology based on identifying and mobilizing universal laws (see LAW, SCIENTIFIC).

Hartshorne’s position was based on the writings of nineteenth- and early twentieth-century German geographers. They did not merely influence Hartshorne’s interpretation: they were his interpretation. The nature of geography was determined ‘in light of the past’. That past, or at least the past on which Hartshorne drew, was strongly influenced by neo-KANTIANISM that separated geography and history from other sciences because they were concerned with the unique and non-repeatable. Geography and history, Hartshorne argued, were IDEOGRAPHIC, NOT NOMOTHETIC. While geography was a SCIENCE, in that it provided ‘organized, objective knowledge’ (Hartshorne 1939, p. 130), the geographical units in which facts were organized, of which the most important were REGIONS, were unique and non-repeatable. Geography was ‘the study of areal differentiation’ and was ‘most clearly expressed in REGIONAL GEOGRAPHY’ (Hartshorne, 1939, p. 468). Methodologically, what followed – and marked geography as exceptionalist in Schaefer’s sense – was an inability to deploy scientific laws, because laws were predicated on generalization and repetition of phenomena. Hartshorne (1939, p. 446) wrote, ‘We arrive, therefore, at a conclusion similar to that which Kroeber has stated for history: “the uniqueness of all historical phenomena. . . . No laws or near laws are discovered.”’ The same conclusion applies to the particular combination of phenomena at a particular place. Geographers, therefore, were not able scientifically to explain, or predict or knowingly intervene, but only describe: ‘Regional geography, we conclude, is literally what its title expresses: . . . [I]t is essentially a descriptive science concerned with the description and interpretation of unique cases . . . ’ (Hartshorne, 1939, p. 449).

In contrast, Schaefer, who was an economist and statistician before and during the Second
World War, and influenced during his tenure at the University of Iowa by the logical positivist and former Vienna Circle member, Gustav Bergmann, believed in the unity of science, and a single, common scientific methodology resting on law-based explanation. In his contrary view, geography was not exceptionalist, but a chip off a uniform scientific block: to explain phenomena within or beyond geography ‘means always to recognize them as instances of laws’ (Schaefer, 1953, p. 227). Schaefer argued that geography should pay particular attention to morphological laws taking the form, ‘If geographical pattern (morphology) A, then geographical pattern (morphology) B’ (see MORPHOLOGY).

In his reply, Hartshorne (1955) pulverized Schaefer, even though Schaefer had been dead for two years. While Hartshorne (necessarily) won that battle, Schaefer won the war, as human geography increasingly rejected exceptionalism, first during the formalization of spatial science during the quantitative revolution and later through its embrace of social theory. Geography was to be ordinary, not exceptional.

Exchange
As an activity, exchange has played a more or less critical role in virtually all societies. It has allowed them to exceed the constraints of subsistence, intensify production and diversify patterns of consumption (although by no means equitably), form social alliances and spatial networks of association, organize and reproduce social hierarchies by expanding the reservoir of material surpluses, and generate new layers of social communication through the symbolic dimensions of exchange. Exchange is a precursor to commerce and therefore to a market economy involving transactions of goods and services between buyers and sellers (see capitalism). Hence the central claim of Adam Smith’s influential 1776 treatise, *The wealth of nations* – that a growing social division of labour and specialized production of goods generates economic prosperity without causing society itself to disintegrate – is premised on the possibility of ubiquitous exchange; in other words, markets. But this is hardly a given. Some things (use-values) may never enter the realm of exchange, because society considers it profane to sell them. Additionally, some exchanges may remain individualized and sporadic, and not result in a market (new institutional Economics has shown, for example, how prohibitive transactions costs can hinder individualized exchange from expanding into a market). Contrarily, exchange may not occur as a commodity transaction, or it may occur, as in situations of barter, as a commodity transaction not mediated by the money-form. Finally, the good or service purveyed may take the social form of a gift, with or without expectation of reciprocity. The writings of the Hungarian anthropologist Karl Polanyi (1972) are particularly illuminating in these matters.

Wherever reciprocity is assumed or implied – commercial, barter or gift – there is the further issue of value. In one sense, the issue is straightforward: it seems reasonable to assume that in a dyadic transaction where individuals A and B exchange a good or service, they do so because A has something B wants and vice versa. In short, both A and B have something that the other values. At least two complications arise here. First, there can be no presumption of a transaction of equivalent value without reference to a third, transcendent standard or measure – whether this takes the guise of: (a) a subjective marginal utility principle (hence A and B transact if at least one of them is better off from the transaction in terms of marginal utility and neither is worse off – the so-called Pareto principle of neo-classical economics); or (b) a principle of equilibration of labour time (A and B transact goods containing equal amounts of socially necessary labour time – the historically grounded Marxist scenario of non-exploitation: see labour theory of value; marxian economics).

This already hints at the second complication; namely, that exchange can occur despite the absence of equivalence because of the unequal circumstances of transactors. Take the case of distress sales of crop in a drought year by a cash-strapped farmer. Given the choice between not selling and starving and selling at a loss, the second option is Pareto-superior in terms of marginal utility for both the farmer who sells and the merchant who buys. But it appears to pervert any notion of equivalence. Similarly, take two other examples: the unemployed person who sells plasma to a for-profit corporation or the runaway boy who performs sexual favours in return for money. It is possible to argue in either instance (and economists do) that the transactors are better off in terms of their respective marginal utilities (in the corporation’s case, its marginal utility of profit) – but only, it seems, by compromising on a notion of equivalence that enjoins some sense of symmetry. In short, the
mediation that is required to explain why exchange occurs yields equivocal answers: all we can categorically say is that finite availability of a thing in TIME and SPACE and actual or anticipated social use-value are general underlying conditions for exchange.

Gifts are a subset of exchange. They involve neither mediation by money nor barter. But like these more conventional forms of transactions, they supply individuals with incentives to collaborate in a pattern of exchanges that performatively reproduce society and validate the status of participants as social beings. In The gift: the form and reason for exchange in archaic societies (1990 [1925]), the French scholar Marcel Mauss built on the ideas of Emile Durkheim to show how gifts function as a mechanism by which individual interests combine to make a social SYSTEM – a ‘gift economy’ – in the absence of market exchange. Because the gift is embedded in the economic, moral, religious, political and aesthetic dimensions, Mauss termed it a ‘Total social phenomenon’. Mauss’ essay has been extended in generative ways by social anthropologists such as Claude Lévi-Strauss, Mary Douglas, Pierre Bourdieu and Marilyn Strathern in their efforts to identify non-market logics that cement society. It goes without saying that the gift economy, far from being an archaic social mechanism, remains a constitutive force in contemporary market societies.

exclave A small piece of a state that is physically separate from its main territorial body but remains within its political jurisdiction despite being surrounded by the TERRITORY of another state. Robinson (1959) identified five exclave types by degree of separation from the HOMELAND: normal, as per the definition above; pene-, territories barely connected to the main state in such a way that access must occur via another state’s territory; quasi-, technically disconnected but connected in practical terms; temporary, as the result of an armistice; and virtual, areas treated as exclaves without meeting the strict legal definition. (See also ENCLAVE.)

existentialism A PHILOSOPHY that flourished in the middle to late twentieth century as a radical defence of human freedom. It emerged partly in reaction to TELEOLOGICAL and deterministic theories of human nature that saw human beings as determined by their biology, by the environments in which they found themselves, or by their social status or economic position. It also emerged in direct response to the racialized ideologies and geopolitics of a colonial (see COLONIALISM) and COLD WAR world. Against notions of human subjects, peoples and CULTURES determined by their ‘nature’, constrained by their ‘essence’ or being the mere ‘bearers’ of their class functions, existentialism argued that human beings were free subjects, whose existence defined who and what they were. For Heidegger (1962 [1927]), the ‘essence’ of this finite SUBJECT, this ‘being-in-the-world’, was that it was thrown into a world not of its own making and radically oriented to this world through projects, mood, will and other dispositions. The ONTOLOGY of finitude was, for the existential subject, a life to be lived, with ‘no-exit’ but death and along the way a profound anxiety and, at times, dread in the face of the individual’s immense responsibility for his or her own life.

Existentialism emerged in HUMAN GEOGRAPHY in the 1970s, as part of a desire to re-focus geographical enquiry away from the reductive abstractions of SPATIAL ANALYSIS and structural MARXISM. It focused on the capacities of HUMAN AGENCY, and in so doing sought to be a corrective to the overly essentialist arguments of much CULTURAL and HISTORICAL GEOGRAPHY (see ESSENTIALISM), to the structural arguments of POLITICAL ECONOMY and to the abstractions of SPATIAL SCIENCE. It focused on how human beings at once live in and make the SPACES, PLACES and LANDSCAPES that they inhabit (Samuels, 1978, 1981). Far from being an abstract science of spatial relations, existential geographies were concrete descriptions of everyday LIFEWORLDS, and were engaged with the ETHICS and VALUES of what human beings understand to be the meaning of their lives and worlds (Entrikin, 1976; Tuan, 1976b; Relph, 1981, pp. 187–91).

Radical geographers have been sceptical of existentialism, tending to see it as overly focused on the subjective experiences of individuals; a kind of IDEALISM that treated lived experience (with its anxieties and feelings of loss, uncertainty or dread) as indicative of a universal condition of existence instead of a concrete situation produced by a historical and oppressive SOCIETY. In Marcuse’s (1972, p. 161) view, by hypothesizing determinate historical conditions of human existence as
ontological and metaphysical characteristics, existentialism became part of the IDEOLOGY it attacked: its radicalism was illusory (cf. CRITICAL THEORY).

exit, voice and loyalty A theory of consumer influence on the quality of PUBLIC GOODS developed by Hirschman (1970), who argued that service quality is likely to be lower in monopoly conditions than in situations where consumers have a choice. With the latter, the following options are available to consumers who consider a service either inefficient or ineffective:

- exit – consumers transfer to an alternative supplier;
- voice – consumers complain about the service, threatening exit if they are not satisfied with the response; or
- loyalty – consumers remain with their current supplier, without either exercising voice or threatening exit.

The higher the (exit) costs of switching suppliers, the lower the potential impact of voice, because suppliers can assume loyalty; under monopolies, voice need have little impact on service quality. Although individual voice may be ineffective, however, collective voice through organized pressure groups may have more POWER over suppliers; such power may be unequally distributed, however, with wealthier people better able to mobilize support and sustain their cause.

Hirschman’s ideas have been developed by governments in recent decades by one or more of: PRIVATIZATION policies, placing former PUBLIC SERVICES in the private sector, believing that competition will lead to improved quality; creating quasi-MARKETS within public services (among health care providers, for example), with the same general expectation; or by promoting choice, through providing information (as in school performance league tables), which consumers can use in considering exit strategies. (See also NEO-LIBERALISM; PUBLIC–PRIVATE PARTNERSHIPS; TIEBOUT MODEL.)

exopolis A new city located beyond existing urban forms (see EDGE CITY). Soja (1996a) defines it as representing a new form of URBANISM. The exopolis turns ‘the city inside-out and outside-in at the same time’, he suggests (p. 239). In this conception, functions formerly associated with CENTRAL BUSINESS DISTRICTS and commuter SUBURBS are not merely transposed, but their character and relationships are reconfigured. ‘Exopolis’ and ‘edge city’ are terms that indicate attempts to understand cities beyond the traditional framework of the CHICAGO SCHOOL (cf. LOS ANGELES SCHOOL) and to analyse urban processes at the city-regional scale (Brenner, 2002).

explanation A statement that identifies the essential reasons for the occurrence of a given event or phenomena. Reasons can be physical causes, mental states, contextual circumstances or even beneficial consequences. For each of these different kinds of reasons to count as an explanation, they must be linked to the event or phenomena by set of general rules (and at the extreme by universal laws). For example, to explain why my copy of the Dictionary of human geography just fell off the desk, I must connect that specific event to a wider set of laws governing motion and gravity. Once the reasons behind the occurrence of a phenomenon or event are determined, the world is revealed as it really is. As Pierre Duhem (1962 [1906], p. 19) put it: ‘To explain is to strip the reality of the appearances covering it like a veil, in order to see the bare reality itself.’

Geographers have been trying to discern ‘bare reality’ ever since the nineteenth century, when the discipline was first institutionalized. ENVIRONMENTAL DETERMINISM was initially a favoured explanatory form in which variations in CLIMATE were posited as the reason for geographical variation in human behaviour, beliefs and institutions. Discussions of explanation as an idea, however, did not emerge until the QUANTITATIVE REVOLUTION in the 1960s. In contrast to those who insisted that GEOGRAPHY, like history, had to be conducted under the sign of EXCEPTIONALISM, the proponents of SPATIAL SCIENCE insisted that their ‘new’ geography was a science like any other, and thus had to meet the strictures of scientific explanation established by PHILOSOPHY. Those strictures were originally formalized by Hempel and Oppenheim in 1948, and known as the Deductive–Nomological (D–N) model. Scientific explanation rested on applying a deductive syllogism to a combination of general LAWS and initial empirical conditions. For example, explaining why the Dictionary just fell off my desk would involve linking by means of a deductive syllogism the particularities of that event to a scientific law (e.g. the law of gravity).

Within the PHILOSOPHY of SCIENCE, the D–N model provoked, and continues to
provoke, significant discussion, and there have been several refinements and alternatives (Salmon, 1990). Harvey (1969) made the D–N model the gold standard for explanation in geography, but even at the time he recognized that few geographical events could be located within such a stringent framework, given the absence of geographical laws on which explanation would have to depend. By the late 1970s there was a movement away from the D–N model of explanation. Geographers were still concerned to explain events and phenomena, but they cast around for less narrowly conceived approaches, ones that recognized that the discipline centred on specific and contingent case studies rather than a larger statistical universe of events. For many human geographers in the 1980s the philosophy of realism, with its conceptual vocabulary of causal powers and liabilities, and contingent and necessary relations, offered a consistent explanatory framework couched in terms of causation and contingency. While realism is still in use, there is a sense that even its definition of explanation remains too closely defined by a natural scientific sensibility. Consequently, it is inappropriate for those forms of human geography that draw upon interpretive, non-essentialist and even non-representational theory. The task is to re-conceive explanation in a form appropriate to human geography’s new guise.

exploration At its basic level, exploration is usually taken to refer to the growth of knowledge of the globe that resulted from various voyages of discovery and scientific expeditions. But the very vocabulary of discovery and exploration is contested by revisionists, who query its appropriateness in contexts where it is more morally responsible to speak of invasion, conquest or occupation. The reason is that these labels unmask the pretended innocence and ethical neutrality that the standard scientific-sounding idioms convey (see ethics).

Whatever the allocation of moral accountability, there can be no doubting the significance of what Driver (2001) calls the ‘cultures of exploration’ on the scientific enterprise in general and the development of geography in particular (see also geography, history of). Traditional chroniclers of these exploits have tended towards a progressivist interpretation of scientific knowledge, cartographic history and global awareness (Baker, 1931). The vast maritime expeditions of Chêng Ho from 1405 to 1433, for example, have been commended for their contributions to Chinese marine cartography and descriptive geography, although, in contrast to later voyages, the purpose of the mission was neither the garnering of ‘scientific’ information nor commercial conquest (Chang, 1971). Similarly, the writings of Ibn Battuta during the late Middle Ages have been read as an encyclopaedic conspectus of the Islamic world (Boorstin, 1983).

It is, however, with the European voyages of Reconnaissance during the fifteenth and sixteenth centuries that putative connections between scientific ‘progress’ and geographical ‘exploration’ begin to be more closely associated (see also science, travel-writing). Writers such as Hale (1967), Parry (1981) and O’Sullivan (1984) suggest that the first scientific laboratory was the world itself and that ‘the voyages of discovery’ were in a fundamental sense experiments to test the validity of Renaissance geographical concepts. In such scenarios, the names of Bartholomew Dias, Vasco da Gama, Christopher Columbus, Ferdinand Magellan and, perhaps most of all, ‘Prince Henry the Navigator’ assume heroic status.

Indeed, the reciprocal links between voyages of exploration and scientific enterprises were deep and lasting. Francis Bacon reflected in his Novum organum of 1620 (§ lxxxiv) that the opening up of the geographical world through such expeditions foreshadowed the expansion of the ‘boundaries of the intellectual globe’ beyond the confines of ‘the narrow discoveries of the ancients’. Support for this interpretation has come from those attaching crucial significance to the Portuguese encouragement of navigational science and mathematical practice through the work of the Jewish map- and instrument-maker Mestre Jacome. This Jewish tradition of Mallorcan cartography, instrumentation and nautical science was perpetuated by Abraham Zacuto and Joseph Vizinho, while Francesco Faleiro, Garcia da Orta and Pedro Nunes did much to further medicinal botany, cartography and natural history during the first half of the sixteenth century (Goodman, 1991). Such accomplishments have been canvassed to substantiate the claim that this Jewish style of sixteenth-century Portuguese science provided the catalyst for ‘the emergence of modern science in Western Europe’ (Hooykaas, 1979; Banes, 1988, p. 58).

Nevertheless, even partisan commentators concede that the scientific advances of the
‘Age of Discovery’ were by-products of commercial, evangelistic and colonial motives. Ostensibly more scientific were the Pacific exploits of Enlightenment figures such as Louis Antoine de Bougainville, James Cook, Joseph Banks, the Forsters, Jean François de la Pérouse and George Vancouver (Beaglehole, 1966). And yet with them too political factors loomed as large as scientific ones: pre-voyage briefings on settlement possibility, RESOURCE inventory and the staking of colonial claims all revealed the strategic significance of everything from cartographic survey to ethnographic illustration (Frost, 1988). Still, the scientific achievements were substantial – Cook, for instance, took with him astronomers, surgeons and naturalists, and successfully completed an accurate recording of the transit of Venus. Precisely the same was true of later explorations in South America and Central Africa. Alexander von Humboldt and Aimé Bonpland, for example, used their South American findings at the turn of the nineteenth century to break the bonds of the static taxonomic system of Linnaeus, and ultimately to create a distinctive mode of scientific investigation – what Cannon labelled ‘Humboldtian science’ – in which ‘the accurate, measured study of widespread but interconnected real phenomena’ was interrogated ‘in order to find a definite law and a dynamic cause’ (Cannon, 1978, p. 105; cf. Dettelbach, 1996). Again, Roderick Murchison, who has been dubbed England’s scientist of EMPIRE, virtually orchestrated the British colonial assault on Central Africa in the Victorian period through his oversight of the Royal Geographical Society, and used a variety of explorers to test his own geological theories there (Stafford, 1989).

There is not space here to delineate in any detail the scientific contributions of a host of other exploratory ventures: the Napoleonic survey of Egypt, Baudin’s deadly mission to ‘New Holland’, the succession of Russian voyages into the Pacific by Krusenstern, Kotzebue and Lütke, the Royal Geographical Society’s efforts to reduce the Australian outback to cartographic enclosure, Lewis and Clark’s western territorial expedition, Darwin’s Beagle circumnavigation, the United States Exploring Expedition under Charles Wilkes, the voyage of T.H. Huxley on The Rattlesnake, a variety of late Victorian ventures to West Africa, A.R. Wallace’s sojourn in Borneo, the oceanographic survey of The Challenger, and expeditions to the poles in the early decades of the twentieth century, to name but a very few. Chief among their scientific achievements were the discovery of numerous unknown species of plants and ANIMALS, new theories of organic dispersal, novel interpretations of human cultures, the mapping of fossils and strata on a global scale, cartographic intensification and advances in astronomical observation. The power of this scientific legacy is so engrained in the discipline’s collective memory that various expeditionary ventures continue to receive the sponsorship of institutions such as the Royal Geographical Society and the National Geographic Society, and to provide a language in which to speak of geographical excursions into other threatening environments, such as urban ethnic ‘no-go’ areas.

The acquisition of scientific knowledge by explorers was a multifaceted enterprise and raised critical epistemological questions that have persisted up to the present day (see EPISODEMOTHERY), not least in settings where expeditionary SPACE is itself experimental space (Powell, 2007). The accumulation of scientific knowledge required careful management. First, the crying need to discipline distant observers in the effort to standardize their findings found expression in works such as the Admiralty’s 1832 Hints for collecting animals and their products, Richard Owen’s Directions for collecting and preserving animals (1835) and later the RGS’s Hints to travellers (1854). Works of this stripe continued a long-standing tradition that included John Woodward’s Brief instructions for making observations in all parts of the world (1696). The production of manuals such as these was part of an exercise in what might be called the geography of TRUST; namely, how to ensure observational reliability and disciplined data-gathering (Carey, 1997, 2006). Second, the scientific knowledge gleaned from explorations involved not only the assemblage and movement of objects, both natural and cultural, around the world, but their re-conceptualization and reclassification according to some prevailing norm or taste (Thomas, 1991; Dritsas, 2005; Hill, 2006a, b). Third, the transformation of local data into universal knowledge that was critical to exploration science involved metrological standardization and thus the production and calibration of precision instruments (see INSTRUMENTATION).

The significance of expeditionary exploits, however, cannot be restricted to matters of cognitive ‘progress’. And merely stating that the growth of these scientific knowledges was situated within the framework of IMPERIALISM
Exploration is to pay scant attention to a whole suite of issues to do with the construction of Western identity, the representations of ‘exoticism’, the inscription of ‘otherness’, the reciprocal constitution of scientific discourse and colonial praxis (see Colonialism) and the Deconstruction of cartographic Iconography.

CULTURES of exploration were thus woven with political, artistic and literary, as well as scientific, threads. It was, for example, as a consequence of the European Age of Exploration/Reconnaissance/Conquest that the idea of the ‘west’ and ‘Western-ness’ received its baptism. Europe’s sense of distinctiveness from the regions that the navigators encountered was embedded in a discourse about identity that represented ‘the West’ and ‘the Rest’ in the categories of superiority–inferiority, power–impotence, enlightenment–ignorance and civilization–barbarism (Hall, 1992b). Seen in these terms, Europe’s rendezvous with the New World in the fifteenth and sixteenth centuries was as much a moral event as a commercial or intellectual one, and induced a sense of ‘metaphysical unease’ because it confounded standard conceptions of human nature (see also Pagden, 1993).

The construction of this ‘discourse of the West’, of course, depended crucially on the idioms in which the new worlds were represented. The categories, vocabularies, assumptions and instruments that the explorers brought to the encounter were, understandably, thoroughly European, and so the worlds of ‘the other’ were interrogated, classified and assimilated according to European norms. That the language of the engagement was frequently gendered, moreover, facilitated the representation of new landscapes in the exotic categories of a potent sexual imagery intended to indicate mastery and submissiveness.

If the foundations of Western discourse were laid during the fifteenth and sixteenth centuries, they were reinforced during the following centuries when eurocentric modes of representation continued to constitute regional identities. One such construction was what Edward Said termed ‘orientalism’ – a discursive formation through which ‘European culture was able to manage—and even produce—the Orient politically, sociologically, militarily, ideologically, scientifically and imaginatively’ (Said, 1978, p. 3). And, indeed, the idea of the Oriental or Asiatic type certainly gripped Western imaginations. In nineteenth-century Britain, for example, what was termed ‘oriental vice’ in the very heart of England – ‘heathenism in the inner radius’ as it was called – expressed anxieties about the moral authority of Christian England (Lindeborg, 1994).

The procedures facilitating the marginalization of the Oriental, and– at the same time – its critical role in European self-definition, were also perpetuated in other places and in other terms. The variety of representational devices that Cook and his coterie of naturalists and draughtsmen deployed – whether Banks’ abstract taxonomies or Parkinson’s evocation of anthropological variety – succeeded in encapsulating the Pacific world within the confines of European epistemologies. Moreover, their penchant for designating names – the naming of places (see Place Names), peoples and individuals – at once invented, brought into cultural circulation and domesticated the very entities that were the subjects of their enquiries (Carter, 1987). That Cook’s team was engaged in what Salmond (1991, p. 15) terms ‘mirror-image ethnography’ is beyond dispute. But just because their modes of categorization were suffused with the expectations of eighteenth-century society should not be permitted to gainsay the remarkable accuracy of their accounts of physical phenomena.

The cultural politics embedded in these various ventures were further reinforced by the artistic and literary crafts of Western exploration. The evocation of distant peoples and places owed much to the supposedly realist works of visual art produced by painters such as Jean-Léon Gérôme (Nohlin, 1991). Indeed, the standard scholarly practices of science, history and comparative literature were themselves profoundly indebted to artistic representation (Smith, 1960; Stafford, 1984). In the tropical world, for example, travelling artists such as William Hodges and Johann Rugendas gave visual form to the changing discourse of tropicality in which scientific observation and aesthetic preference reinforced one another (Driver and Martins, 2005). In similar vein, the use of photographic technology to ‘capture’ distant sites and sights, served no less to constitute than to represent imperial subjects and spaces (Ryan, 1997). At the same time, overseas escapades provided writers of fiction with resources to stimulate readers’ imaginations. In some cases, this took the form of adventure stories that fostered new senses of heroic masculinity and projected European fantasies onto non-European worlds (Phillips, 1997). In others, evocations of faraway realms were shaped by utopian or dystopian literary tropes, which were deployed by writers not only to imagine foreigners but
to re-imagine themselves (Fulford, Lee and Kitson, 2004).

Evocations such as these contributed massively to the generation of global imaginative geographies (Gregory, 1994). Thus the Americas, in one way or another, were constructed according to European predilections (Harley, 1990; Mason, 1990; Greenblatt, 1991); later, the Pacific was re-composed as a coherent geographical entity (MacLeod and Rehbock, 1994) – as was ‘darkest Africa’ (Brantlinger, 1985) – as these toponymic labels were brought into cultural currency. The same can also be said of the tropical world – a conceptual space that came into being courtesy of the conjoined forces of geographical exploration, colonial administration and tropical medicine (Arnold, 1996b; Livingstone, 1999; Stepan, 2001). Moreover, exploration and exhibition frequently went hand in hand, as in the case of Egypt, which found its people and places enframed, ordered and exhibited to suit European curiosity (Mitchell, 1988).

Space does not permit further elucidation of such motifs in other regions. Suffice to note that in the African context, according to the Comaroffs (1991, p. 313), European colonization was often less a directly coercive conquest than a persuasive attempt to colonize consciousness, to remake people by redefining the taken-for-granted surfaces of their everyday worlds. Yet here too the temptation towards ‘monolithizing’ the encounter must be resisted: the moral significance of African environments became a source of endless debate about the effects of a tropical climate on white constitution and the connections between black racial character, biological make-up and physical geography (Livingstone, 1991). In South America, it was Humboldt’s ‘interweaving of visual and emotive language’ that contributed so powerfully towards what Pratt (1992) calls the ‘ideological reinvention’ of ‘América’ – a re-imagining so vivid and so vital that Humboldt’s writings provided founding visions for both the older elites of northern Europe and the newer independent elites of Spanish America.

If these machinations, however tangled their genealogies, satisfied a European sense of superiority through constituting the peripheral regions of the globe in its own terms, those self-same arenas were soon to become pivotal laboratories for scrutiny into human prehistory. In this way, the threat that resided in ‘alien’ human natures could be rendered benign if those races turned out to be the persistent remnants of earlier phases in the story of human evolution. Just as earlier Scottish and French enlightenment thinkers, such as Smith, Ferguson and Buffon, regularly crafted their image of the bestial or noble savage into evolutionary schemes depicting a transition from barbarism to civilization, so early-twentieth-century students of human archaeology used ‘the peoples defined as living at the uttermost ends of the imperial world as examples of living prehistory’ (Gamble, 1992, p. 713: see also primitivism). Thereby their identities remained engulfed within the imperatives of Western scientific scrutiny. They also remained subordinated in the cartographic representations that invariably accompanied the exploratory process. Whether in their use as military tools, in their advocacy of colonial promotion, in their marginal decorations, in their systems of hierarchical classification or in their imposition of a regulative geometry that bore little reference to indigenous peoples, maps became the conductors of imperial power and Western ideology (see cartography, history of).

Imperial readings of exploration, however, can serve to obscure as much as they reveal when presented with monolithic tenacity. Treating ethnicity as simply the invention of missionary activity, colonial officialdom or early anthropology, for example, is insufficiently flexible to take the measure of exploration encounters. Such scenarios are not sufficiently subtle to discern the complex role of the missionary movement – to take one activity too easily typcast as the servant of cultural imperialism – in emerging senses of nationhood. Thus we are only beginning to appreciate how, in the African context, a missionary passion to render indigenous languages into written form (for the purpose of Bible translation) provided mother tongue cultures with a vernacular literacy that in turn cultivated nascent senses of nationhood. Through translation, written languages were created and a vocabulary for national self-consciousness fostered (see Sanneh, 1990; Hastings, 1997).

The history and geography of ‘exploration’, then, turns out to be far from antiquarian chronology. Rather, it focuses centrally on the identity of people, the wielding of power and the construction of knowledge; and it is precisely because these are entangled in such complex and intricate ways that their elucidation is of crucial importance to the future course of human history.

Ballantyne (2004); Burnett (2000); Driver (2001a); Fernandez-Armesto (2006).

**exploratory data analysis (EDA)** An attitude to quantitative methods that encourages and licences a ‘trial-and-error’ approach. The term was popularized by the statistician John Tukey, who recognized two approaches to data analysis. Exploratory approaches uncover patterns and anomalies in the data – he likened this to numerical detective work whereby evidence is gathered. Confirmatory data analysis, in contrast, equates to significance testing and probabilistic inference, as in a trial where evidence is put in a formal manner and a judicial decision made ‘beyond reasonable doubt’. The exploratory approach is based on the notion that ‘better a good answer to a vague question than a precise answer to the wrong one’ and that ‘by assuming less you learn more’. It has encouraged the use and development of smoothing procedures that reveal patterns in data, of diagnostic, often graphical, tools for exposing where assumptions are not met, and of procedures that are robust/resistant to anomalies (outliers) in data. Johnston (1986a, ch. 6) argues that such data analysis should be an integral part of a non-positivist, realist approach to doing geography. Exploratory spatial data analysis (ESDA) extends EDA to detect spatial properties of data.

**export processing zone (EPZ)** A geographically delimited territory providing special facilities for foreign branch plants, using imported inputs to manufacture commodities for export. Plants locating within the territory are subsidized with some combination of infrastructure, tax advantages, relaxed labour regulations, and eased imports and exports. EPZs provide incentives to attract foreign investment to low-wage countries, but also high-wage countries (there are 300 in the USA). EPZs typically locate near the periphery of countries, reinforcing external orientation. Workers are predominantly women in non-skilled jobs, often under draconian labour relations. Since the first EPZ in Ireland in 1956, there has been an explosion since the mid-1970s to over 5,000 zones, with employment exceeding 40 million, in more than 100 countries.

**external economies** Closely related to the concept of externalities, external economies are economic benefits that derive from sources outside an organization, such as a firm. These benefits, which can include the contributions of specialist suppliers, subcontractors or skilled workers hired from the local labour market, accrue to individual companies even though they are generated elsewhere. In cases where they are not available, companies must bear the costs of producing them internally.

The benefits of external economies are often captured locally, declining with distance. An early formulation of this argument came in the shape of the growth pole theory developed by the French economist François Perroux in the late 1940s (see Darwent, 1969), which was influential in regional policy debates in the 1960s and 1970s. Growth poles were geographical concentrations of economic activity, often dominated by a single industry or a closely related group of industries, in which local firms yielded the economic benefits (or positive externalities) of co-location with other firms. In this context, the growth of individual firms might stimulate business amongst suppliers (through so-called backward linkages) and/or amongst users of outputs or services (through forward linkages). Driven by propulsive industries, successful growth poles are characterized by mutually beneficial, cumulative economic growth. These arguments recall Alfred Marshall’s account of ‘industrial districts’ in nineteenth-century England: in Sheffield’s cutlery quarter, for example, firms clustered together to capture benefits of shared access to critical factors of production such as skilled labour and technical knowledge.
that circulated, Marshall observed, as if ‘in the air’ (see Krugman, 1991).

These arguments have been vigorously rejoined in recent years in discussions of industrial clusters, agglomeration economies, and flexible accumulation. Allen Scott (1988b), for example, has argued that the tendency towards vertical disintegration – in which firms increasingly turn to the market to supply key inputs and services, rather than organizing these internally – is a defining characteristic of the contemporary form of post-Fordist capitalism. As firms become increasingly reliant on external inputs, the competitive imperative of minimizing transaction costs induces geographical clustering, which in turn accounts for the continuing significance of localized centres of production such as Hollywood and the City of London, even in highly globalized industries such as movie production and finance. Likewise, Storper and Walker (1989) contend that the process of capitalist industrialization is increasingly driven by external economies of scale and economies of scope which in the contemporary phase of growth accrue to entire industries rather than just individual firms. In this analysis, technological innovation (such as the development of integrated circuits or the internet) assumes the character of a shared resource, with spillover benefits for the economy as a whole. In contemporary industrial districts, such as the Emilia-Romagna region of Italy, it is also argued that even rival firms reap external economies from a climate of trust and reciprocity, resulting in collaborative initiatives in areas such as training, design, marketing and research. These are what Michael Storper (1997b) calls ‘untraded interdependencies’, which are increasingly salient in the contemporary era of vertically disintegrated, flexible capitalism.

**externalities** Costs or benefits borne by an individual not directly involved in the activity; or, in broader terms, the social or environmental consequences of private choices. Positive externalities (sometimes known as external economies) represent benefits accruing to third parties; for example, those arising from a bee-keeper located next to an apple orchard, or a group of residents living near to high-quality local schools. Negative externalities (which are also known as external diseconomies) refer to the downstream costs of choices or activities for third parties, the classic illustration of which is pollution. This is a key concept in environmental economics, exposing some of the limits of purely market-based systems of coordination, since negative externalities are costs that fall on actors other than those directly involved in the activity. A tragedy of the commons may result, in which individually motivated actors ‘free-ride’ on collective or shared resources, capturing individual benefits, but with a net detriment for society as a whole, as shared resources are depleted or degraded (see Hardin, 1968). Responses to these dilemmas can include governmental regulation such as ‘green taxes’, or market-mimicking strategies such as pollution pricing.

In economic geography, an example of negative externalities is the common problem of firms under-investing in skills training: these costly and risky investments can be evaded by individual firms if they poach skilled workers from other firms, or otherwise plunder the resources of urban labour markets. The aggregate outcome is an under-investment in skills across the urban labour market, as even scrupulous employers are deterred from training their own workers for fear of poaching (see Peck, 1996). Meanwhile, examples of positive externalities include those ‘agglomeration economies’ captured by firms locating near to suppliers and customers. Scott (1988c) reveals how many so-called ‘flexible firms’ are narrowly redefining the boundaries of their organizations, focusing on core competences while buying in an increasingly broad array of goods and services from other firms (e.g. contract catering, management consultancy, temporary-agency labour). In order to minimize the transaction costs associated with such activities, flexible firms are induced to cluster together in space, generating the dense networks of inter-firm relations that characterize ‘new industrial spaces’ such as Silicon Valley.

Take the example of Wal-Mart, the world’s largest retailer and the USA’s biggest employer (see Wrigley, 2002; Brunn, 2006). The long-running debate around the local community impacts Wal-Mart centres on externalities. Critics of the company allege that its practice of paying low wages is a form of free-riding on public welfare systems, since many of Wal-Mart’s employees qualify for government programmes designed for the poor, such as food stamps, subsidized housing and publicly funded healthcare. Other negative externalities follow from Wal-Mart’s ability to hold down prices (due to its market power), which often drives smaller, neighbourhood retailers out of business. On the other hand, defenders
of the company counter that most of the externalities are positive ones: Wal-Mart contributes to local social welfare by generating employment (particularly by locating in low-income neighbourhoods that have been largely abandoned by large employers) and by reducing prices for customers, many of whom also tend to be poor. A major store can also generate additional sales for a range of local companies such as restaurants and gas stations, another form of positive externality. JPe
factor analysis  A statistical procedure for transforming a (variables by observations) data matrix into a new matrix whose variables are uncorrelated. Unlike principal components analysis, the number of variables in the new matrix is less than in the original as the unique variance associated with each original variable is excluded. The new variables – termed factors – are composites of the original variables: the factor loadings (interpreted in the same way as correlation coefficients) indicate the relative strength of the relationship between the original and new variables; the factor scores provide a measure for each observation on the new variables (weighted according to the factor loadings). The matrices of factor loadings may be rotated in order to enhance interpretation of the new variables. Most rotations aim to maximize the relationship of the original variables to just one factor; they may be either orthogonal – retaining the uncorrelated nature of the factors – or oblique – allowing intercorrelations among factors.

Factor analysis may be used either inductively, to identify groups of interrelated variables (cf. exploratory data analysis), or deductively, to test hypotheses about interrelationships. Factor analysis and the associated principal components analysis (the two are often treated – although wrongly – as the same procedure) have been extensively used within geography since its quantitative revolution, in two ways: as a means of identifying socio-spatial order in large data sets (not least in the automated treatment of the raw data in remote sensing); and to produce composite variables that could be used to represent and map general concepts – such as economic development. It is still widely used in ecological studies (cf. factorial ecology).

Suggested reading

factors of production The ingredients necessary to the production process; that is, those things that must be assembled at one place before production can begin. The three broad headings conventionally adopted are land, labour and capital. Sometimes the fourth factor of ‘enterprise’ is added, to recognize the contribution of the ‘entrepreneur’ or risk-taker and the legitimacy of a special return to this participant in the productive process. However, in the current complexity of economic organization, it is hard to distinguish enterprise from general management functions, so this factor is more appropriately subsumed under labour. The combination of factors of production reflects the state of technology applied in the activity in question; for example, whether it is capital-intensive or labour-intensive.

Land is necessary for any productive activity, whether it is agriculture, mining, manufacturing or services. Land may be a direct source of a raw material, as with mining, or it may be required for the cultivation of a crop or to support the physical plant of a manufacturing activity. Modern industry requires increasing quantities of land, as factory sites and for such associated uses as storage, roadways and parking.

Labour requirements vary with the nature of the activity in question. Some need numerous unskilled workers while others require more skilled operatives, technicians, office personnel and so on. The availability of particular types of labour can have an important bearing on the location of economic activity. Despite the growing capital-intensity of modern industry, cheap labour with a record of stability is still an attraction. That the value of production can ultimately be traced to the factor of labour is central to the labour theory of value.
FAIR TRADE

*Capital* includes all things deliberately created by humans for the purpose of production. This includes the physical plant, buildings and machinery (i.e. fixed capital; cf. SUNK COSTS) plus the circulating capital in the form of stocks of raw materials, components, semi-finished goods and so on. Private ownership of capital and land is the major distinguishing feature of the capitalist MODE OF PRODUCTION, which carries with it important implications for the distribution of income and wealth (see MARXIST ECONOMICS; NEO-CLASSICAL ECONOMICS).

The conventional categories of land, labour and capital (and enterprise) can serve an ideological role in legitimizing the differential rewards of the various contributors to production under CAPITALISM. The concept of productive forces is preferred in SOCIALIST ECONOMICS. In any event, for practical purposes these broad categories tend to be subdivided into the individual inputs actually required in particular productive activities.

Suggested reading

**fair trade** The demand that producers from poorer countries should not be denied the legitimate maximum rewards from their sales by the actions of richer countries or other powerful agents. Fair trade campaigns go back a long way and embrace several related issues. Indian nationalists complained about a system of Imperial Preferences and asked for a measure of protection to help set up infant industries in areas such as iron and steel. In the 1950s, Oxfam took a lead in promoting fair trade ideas under the slogan ‘Helping by Selling’. Similar ideas were taken up in the 1960s, when many African countries demanded ‘TRADE not AID’. This slogan became the motif of the first UN Conference on Trade and Development, held in Geneva in 1964. Other trade justice campaigns have complained about export dumping by richer countries. Still others worry about pressures being placed on developing countries to liberalise their own markets too quickly. Ha-Joon Chang (2002) has charged that almost all of today’s advanced industrial economies benefited from protection. Now, however, they and their representatives in the INTERNATIONAL MONETARY FUND (IMF) and WORLD TRADE ORGANIZATION (WTO) want to kick away that ladder to success in the developing world (see NEO-LIBERALISM).

Campaigns to ensure more open and equitable access to richer MARKETS for developing world producers continue to be important in the fair trade pantheon. Developing countries pressed for liberalization of agricultural markets in the European Union and North America during the World Trade Organization talks held in Hong Kong in 2005 (Stiglitz and Charlton, 2006). The fair trade issue was also pushed strongly by the Make Poverty History campaign. Sugar producers in West Africa or the Caribbean will not receive a fair return for their crop when countries in the richer world offer large subsidies to domestic producers of sugar cane or beet. More recently, fair trade campaigners have put the spotlight on trade negotiations that link small producers to some of the world’s largest or most powerful companies. Take the case of coffee. How are small producers in Central America meant to strike fair deals with giant coffee purchasers when those same companies can use their immense purchasing power to strike better deals for themselves with producers in Brazil or Vietnam? The answer, in part, is for small producers to form CO-OPERATIVES. They can then work with campaigning groups to persuade Starbucks and other coffee giants of the commercial value of selling ‘fair trade’ brands in their outlets. At this point, fair trade campaigns rub shoulders with calls for ethical CONSUMPTION (Nicholls and Opal, 2005).

Questions of market access and fair trade also take shape within poorer countries. Many small producers in the developing world are hurt by governments that saddle them with paperwork. It has been reported that some banana growers in the Central African Republic take over 110 days to get their bananas on a ship to Europe, and need more than 35 signatures to get them on board. Each signature creates an opportunity for corruption, or rent-seeking behaviour. Trading structures remain distorted, rather than open or developmental, and primary producers continue to lose out.

**falsification** The criterion proposed by the philosopher of science Karl Popper (1902–94) to demarcate science from non-science. In Popper’s view, only statements capable of falsification – that is, those possessing the capability of empirical refutation – were scientific. Statements that could not be falsified – that is, those unable to be proved wrong – were
non-scientific. For Popper, the division between falsifiable and non-falsifiable statements was inviolate, allowing consistent separation of science from non-science.

Popper first proposed falsification in his 1935 book *Logik der Forschung* (translated as *The logic of scientific inquiry;* Popper, 1959). It was written as a response to discussions at the Vienna Circle of logical positivism that he attended, although it was a group to which he was never admitted as a full member. Logical positivists argued for the principle of verification, according to which the truth of a scientific statement was given by its correspondence to real-world observations. Popper, dubbed by one member of the Vienna Circle, Otto Neurath, as ‘the official opposition’, claimed to the contrary that scientific statements were never verified, only falsified. Because no one is omnipotent, it is impossible to know whether in the future a scientific claim will be disproved by a disconfirming instance (and a single disconfirming instance is all that is required to refute a general claim). For example, the verified truth of pre-eighteenth-century natural scientists in Europe that all swans were white was invalidated when Captain Cook sailed to Australia and found black swans. The growth of scientific knowledge, as Popper (1963) would later claim, was based not on verifying theories, but on falsifying them, and in the process developing alternatives that were less worse; that is, not yet falsified. This was one of the basal propositions of Popper’s development of critical rationalism.

In *The Structure of Scientific Revolutions*, Kuhn (1970 [1962]) provided the root of a trenchant critique of Popper’s position. Kuhn portrayed the trajectory of science as punctuated by periods of fundamental change he called paradigm shifts; for example, the move from Newtonian to Einsteinian celestial mechanics. During such shifts, everything was in flux, Kuhn argued, including criteria of falsification. Popper had made such criteria fixed and constant and yet, as Bernstein (1983, p. 71) later put it, ‘data or evidence do not come marked “falsification”.’ Criteria of falsification are moving elements, not existing outside of debate, and settled only after change has happened.

Falsification should have been an important criterion for geographers during the period of the quantitative revolution, when the discipline modelled itself most explicitly on the natural sciences. But it wasn’t. If anything, that disciplinary move was backed by logical positivism, the very philosophy Popper thought he had dispatched in the 1930s. Alan Wilson (1972, p. 32), one of the leaders of geography’s quantitative revolution, did suggest the importance of falsification in a 1972 statement: ‘The essence of the scientific method . . . is an attempt to disprove theory – to marshall observations to contradict the predictions of the theory.’ But it was programmatic, and never realized in Wilson’s practice, or the practices of anyone else in geography. This was precisely Kuhn’s point, and later developed in science studies: falsification could never be realized.

**family reconstitution** A method used in historical demography to create measurements in the absence of data on demographic stocks and flows made available through censuses and vital registration that applies nominative linkage techniques to baptisms, marriages and burials recorded in parish registers (see Fleury and Henry, 1965). The technique can also be adapted for use with genealogies (see Henry 1956). It starts from a marriage and links baptisms and burials of children born to the couple as well as their subsequent marriages. Family reconstitution rules devised originally for use with French parish registers by Louis Henry have been adapted for use with registers elsewhere, with a view to establishing a population at risk or under observation so that age-specific mortality and fertility rates can be calculated. Marriage age can be derived by linking baptisms and marriage dates and information can be extracted that will enable fecundity, birth and pre-nuptial pregnancy rates to be computed (see Wrigley, 1966a). Linkage is far more successful where migration is low, and consequently cities and large towns have rarely benefited from the technique, which has been used primarily to reconstruct the population of villages and smaller market towns (see Wrigley, Davies, Oeppen and Schofield, 1997).

**famine** A relatively sudden event involving mass mortalities from starvation within a short period. Famine is typically distinguished from chronic hunger, understood as endemic...
nutritional deprivation on a persistent basis (as opposed to seasonal hunger, for example). Definitions of famine are fraught with danger because (i) cultural, as opposed to biological, definitions of starvation vary around diverse, locally defined norms, and (ii) deaths from starvation are frequently impossible to distinguish from those from disease.

Nearly all societies have periodically suffered from the consequences of famine. The earliest recorded famine, which occurred in ancient Egypt, dates to 4000 BCE; famine conditions currently threaten parts of the Horn of Africa and parts of North Korea. The dynamics and characteristics of mass starvation in modern times have similar structural properties; however, typically, such famines involve sharp price increases for staple foodstuffs, decapitalization of household assets, gathering of wild foods, borrowing and begging, petty crime and occasionally food riots, and out-migration. According to the Hunger Program at Brown University, the trend in famine casualties has been downward since 1945, but in the late 1980s states with a combined population of 200 million failed to prevent famine within their national borders. Hunger, and famine in particular, is intolerable in the modern world, however, because it is unnecessary and unwarranted (Dreze and Sen, 1989).

Famine causation has often been linked to natural disasters, population growth and war, which produces a reduction in the food supply (Malthus, 1798). But some major famines (e.g. Bengal in 1943) were not preceded by a significant decline in food production or absolute availability, and in some cases have been associated with food export. Recent analyses have focused on access to and control over food resources – sometimes called the food availability decline hypothesis. Sen (1981) argues that what we eat depends on what food we are able to acquire. Famine, therefore, is a function of the failure of socially specific entitlements through which individuals command bundles of commodities. Entitlements vary in relation to property rights, asset distribution, class and gender. Famine is therefore a social phenomenon rooted in institutional and political economic arrangements, which determine the access to food by different classes and strata (Watts, 1983a). Mass poverty and mass starvation are obviously linked via entitlements. Mass poverty results from long-term changes in entitlements associated with social production and distribution mechanisms; famines arise from short-term changes in these same mechanisms. Famine and endemic deprivation correspond to two forms of public action to eradicate them: famine policy requires entitlement protection to ensure that it does not collapse among vulnerable groups (i.e. landless labourers, women). Chronic hunger demands entitlement promotion to expand the command that people have over basic necessities (Dreze and Sen, 1989). Since 1945 India has implemented a successful anti-famine policy, yet conspicuously failed to eradicate endemic deprivation. China, conversely, has overcome the structural hunger problem (even during the socialist period), but failed to prevent massive famine in the 1950s. Africa has witnessed a catastrophic growth in the incidence of both mass starvation and chronic hunger (de Waal, 1997).

The role of state policy and of humanitarian aid figures centrally in the discussions of famine and famine causation. While the public sphere is key in understanding how and why the right to food and the right not to be hungry are made effective, the recent history of famine shows clearly how the state can use famine and humanitarian aid for explicitly political purposes. The case against Stalin and the Ukrainian famine is clear in this regard, and the catastrophic Chinese famine of the late 1950s is a compelling instance of how inept state policies to achieve rapid industrialization backfired, but also how an authoritarian state ignored famine signals and colluded in the deaths of 20 million people (Becker, 1997). Sen (1981) has argued that famines rarely occur in societies in which there is freedom of the press (and in which states are therefore held to be accountable in some way). Humanitarian assistance has also been an object of critique insofar as it itself becomes politicized (and rendered as a business), and often fails to be more than a short-term palliative (rather than assisting in the rehabilitation and reconstruction of famine-devastated communities; de Waal, 1997).

farming Most literally, the land-based, human-managed production of food and fibre by the transformation of seed into crops and/or the raising of livestock (the latter of which is also referred to as pastoralism or ranching). Farming is of general significance for all social scientists, because it is the most routine and widespread way in which humans directly
interact with NATURE, and because adequate food production and consumption has proven to be crucial for the stability of SOCIAL FORMATIONS.

Farming as a capitalist enterprise preceded England’s INDUSTRIAL REVOLUTION, as tenant farmers began cultivating wool for the nascent textile industry (see AGRICULTURAL REVOLUTION). Since the Second World War, the world has seen massive transformation of farming sectors. In the industrialized counties, these transformations began with the proliferation of technologies of INTENSIVE AGRICULTURE, especially those that relied on the development of petrochemical inputs; these technologies were extended to some areas of the THIRD WORLD, with the idea that high-yielding agriculture (see GREEN REVOLUTION) and INDUSTRIALIZATION were keys to DEVELOPMENT (Goodman and Redclift, 1991). Since the 1980s, however, rural populations have substantially declined (see URBANIZATION). The 1970s was a period of farm expansion, owing to the USA selling massive amounts of grain to the Soviet Union, which caused a temporary food shortage and high prices for farmers. The collapse in prices that followed contributed to the international debt crises of the 1980s, which forced many farmers out of business who could no longer pay the farm mortgages they acquired in the previous expansion (Friedmann, 1993). Recent free TRADE agreements have allowed low-cost producers, such as the USA, to dump surplus crops in cash-poor regions and countries, undermining the livelihoods of PEASANTS and small farmers, contributing to even more displacement.

Categorizing patterns of farm land use was a staple feature of traditional AGRICULTURAL GEOGRAPHY (Tarrant, 1974). Farm size has continued to be a major analytic in empirical studies of farming, owing in part to the availability of census data, which are often reported as acres/hectares in production and/or gross sales. As the POLITICAL ECONOMY of agriculture TRADITION came to dominate agricultural geography in the 1980s, more effort was put into developing more theoretically informed typologies of farm business organization and to help explain changes in farming practice (see, e.g., Whatmore, Munton, Little and Mardsen, 1987). These efforts engaged with a long sociological tradition concerned with the CLASS location of farmers and the social organization of farming relative to STATE and CAPITAL (see Buttel and Newby, 1980). LAND TENURE, capital ownership, labour relations, family LIFE-CYCLE and RENT-seeking thus became primary analytics, and the persistence of the family farm, defined as that where FAMILY members provide all or most of the agricultural labour regardless of the extent of its commercial orientation (cf. SUBSISTENCE AGRICULTURE) became a central theoretical question. One widely cited theorization of thisUNEVEN DEVELOPMENT of capitalist agriculture was Goodman, Sorj and Wilkinson (1987). CAPITALISM has developed around farming, they argued, because with its basis in land and biology, farming itself remains risky, while the processes that serve farming are more easily commodified and sold back to the farmer (see AGRARIAN QUESTION; SUBSTITUTIONISM).

Watts (1994a) drew on these arguments in his work on contract farming, noting that the degree to which buyer firms specify required processes and inputs in their contracts has made many peasants equivalent to wage labourers on their own land. Sachs (1996) added that the enduring family basis of farming in most parts of the world has in large part depended on highly gendered divisions of labour within peasant HOUSEHOLDS. In some sectors and regions, however, farming operations themselves are large-scale, capitalist enterprises (Heffernan and Constance, 1994). Highly mechanized corporate farms should be differentiated from PLANTATIONS that, while corporately owned and managed and large in scale, employ many manual labourers.

In the early 1990s, agro-food scholars began to take note of divergent trends in farming and food production. Heightened public concern with food safety and quality, the ecological effects of agriculture and the changing countryside (in some cases depopulation, in others urbanization) seemed to support a turn towards farming that would be more sensitive to ecological concerns and protective of rural livelihoods. In addition, growth in part-time and hobby farming, a resurgence of back to the land sensibilities among those seeking alternative lifestyles, along with a putative shift in national forms of farm regulation away from commodity supports seemed to indicate a ‘post-productivist’ transition in agriculture (Marsden, 1992). While the dramatic rise in organics, for example, seems to provide support for this claim, the European and US farming sectors are state-supported more than ever, albeit in different ways to different ends. Meanwhile, many Third World farming sectors are producing high-value fruits and vegetables under conditions of STRUCTURAL ADJUSTMENT.
Technology-driven INTENSIVE AGRICULTURE has hardly gone away, in spite of increased incidences of biological ‘blowback’ from industrial food production – such as bovine spongiform encephalopathy (BSE), or ‘mad cow’ disease. Driven in part by the twin revolutions in information science and biotechnology, farming itself seems to be moving in directions that belie the opening definition of this entry. Already, surplus commodities, such as corn and oil seed, which have long been a source of livestock fodder, are being deployed for industrial uses. Precision agriculture uses satellite data to determine local variation in soil conditions and plant development, and information technologies to track and fine-tune applications of farm inputs. Genetic engineering has been used to improve crop protection by, for example, engineering natural pesticides or frost protection into plants. The use of genetically engineered livestock or plants to produce medically useful crops – or ‘gene pharming’ – is just in the pipeline, as is the introduction of nutrients or vaccines into existing food crops. These sorts of developments are drawing geographers to new questions and theorizations, many borrowed from the toolkits of SCIENCE and technology studies.

At the same time, many of these technologies carry ecological RISKS and are also leading to unprecedented degrees of PRIVATIZATION. Therefore, they have become a major galvanizing feature of contemporary SOCIAL MOVEMENTS. Since most of these trends point to a continued decline in rural populations, the family farm seems to have achieved heightened IDEOLOGICAL status. Thus, the distinctions between peasant, family and corporate forms are not just academic, but are relevant to political practice, particularly given the re-emergence of discourses of agrarian POPULISM within both institutions of DEVELOPMENT and social-justice oriented social movements (Wolford, 2003).

fascism A politicalIDEOLOGY that formed the basis of political parties and social movements that emerged in EUROPE between the two world wars. The nationalist governments of Adolf Hitler in Germany (1933–45) and Benito Mussolini in Italy (1922–43) are the most notable examples, but fascism was a political force across Europe at the time, including Oswald Mosley’s ‘black shirts’ in Britain, the Iron Guard in Romania and the Croix de Feu in France (Laqueur, 1996). Despite the lack of a seminal intellectual text, the following characteristics of the ideology can be identified: extreme racist NATIONALISM; a desire for a ‘pure’ NATION-STATE that contains just one national group; goals of territorial expansion to include all members of a NATION within the borders of the state (cf. LEbensraum); ANTICOMMUNISM and other forms of working-class organization; VIOLENCE represented as necessary for the survival of the nation and as a pathway to fulfilling innate human needs; a glorification of manliness and gender roles, promoting men as defenders of the nation and women’s primary role in the biological reproduction of the nation (cf. MASculINISM); and a mass politics in which the STATE and the party fuse and mass participation in politics (based upon a cult of the leader) is encouraged. Elements of these ideologies exist in contemporary nationalist political parties across the world, as extreme nationalism is mobilized in the wake of social dynamics (such as IMMIGRATION and a decline in the power of the state) that are identified as ‘threats’.

Political parties in Russia and Serbia display some of these traits, as do the British National Party and some extremist right-wing movements in the USA.

The RACISM of fascist movements is often, but not necessarily, anti-Semitic. Jews are frequently targeted as enemies because, prior to the establishment of the state of Israel, they lacked connection to a particular TERRITORY. Hence, they were seen as disloyal to the nation or inimical to the idea of territorial nation-states. The foreign policy of the Nazi Party was partially informed by the ideas of GEOPOLITIK, which saw territorial expansion as a strategy related to the HOLOCAUST and the extermination of Jews (as well as gypsies, communists and homosexuals), to create a political geography of a ‘pure’ and ‘greater’ Germany (Clarke, Doel and McDonough, 1996: see also GENOCIDE).

Social scientists and historians have debated the social bases of fascism. The idea that the middle classes were the main source of support dominated until recent years, when the notion of a cross-CLASS support for the Nazis emerged. The geography of fascism shows that support is based upon different class coalitions in different localities, within the broader context of economic RESTRUCTURING and inter-state competition (Flint, 2001). Recent scholarship has argued that the support for inter-war fascism was more widespread than
had been believed (Goldhagen, 1996), with ‘ordinary citizens’ rather than committed party members carrying out much of the killing in the Holocaust. This controversial work has contemporary implications as geographers have turned their attention to Genocide, under the label of ‘ethnic cleansing’, in the former Yugoslavia and in Africa.

**fecundity** An individual’s capacity to reproduce (as distinct from fertility, an individual’s actual reproductive performance). A physical (biological) component varies with age and sex, with women reaching peak fecundity between menstruation and menopause, and male fecundity decreasing, but less rapidly, with old age. Infecundity increases with poor nutrition and ill health: the ongoing HIV/AIDS epidemic has reduced fertility levels in many regions both because of the premature deaths of potential parents and because fecundity is impaired (Gregson, 1994). Research also recognizes a social component when, for example, women believe they cannot give birth, and when medical practitioners expressly counsel against giving birth.

**federalism** A form of government in which power and functions are divided between central and regional authorities with the goal of providing autonomy to regional units (Wheare, 1963). Federal forms of government vary widely, but require a written constitution to delimit the roles of different levels of government. Federalist states usually experience a continual political process of defining the degree of centralization and regional autonomy. In states with geographically concentrated ethnic groups (see ethnicity), federalism can reinforce ethnic differences, but it also provides a political solution to ethnic competition for control of the state (Iporukpo, 2004).

Suggested reading

**feedback** A reciprocal effect within a system, whereby change in one variable (A) influences changes in others (B, C), which may then stimulate further change in A. Negative feedback generally maintains the system’s equilibrium: an increase in the number of animals in an ecosystem may stimulate growth in the number of their predators, whose actions then reduce the number of animals to the previous level. Such systems are morphostatic, in dynamic equilibrium; the period between any shock to the system and the return to its equilibrium state is termed its relaxation time. With positive feedback, an increase in A may stimulate increase in B, which in turn stimulates further growth in A, as in the multiplier processes associated with input-output models. Such systems are morphogenic.

**feminism** A diffuse political movement, which has varied over space and time, that aims to identify and dismantle systematic gender inequality, and the myriad ways in which gender differentiation, heteronormativity, masculinism, and phallocentricism naturalize, anchor and relay all kinds of social exclusion, and physical and symbolic violence. It struggles to improve women’s lives across a range of issues: violence against women; sexual harassment; access and equity in schools, workplaces, before the law and within political life; the division of domestic labour; and reproductive rights, among others. It seeks to revolutionize thought in daily life and throughout the arts and sciences, and to undo and reconceptualize the many naturalized qualities attributed to women and men, what counts as knowledge, and the relation between knowledge and practice. Feminist struggles have been important not only for their substantive achievements and goals, but for the process through which these have been sought; Dietz argues that feminist movements in the USA are a living repository of democratic norms and practices that have ‘nearly ceased to be part of the politics of the United States’ (1987, p. 16). Historical accounts of Anglo-American feminism typically distinguish between first-wave (late nineteenth century to the First World War), second-wave (1960–1980s) and third-wave (1980s–) feminisms, although this periodizing risks simplification. For instance, although first-wave feminism is known for campaigns to win women’s right to vote, these were part of broader concerns about women’s rights to education, paid employment, sexual freedom and financial self-sufficiency (Blunt and Wills, 2004).
Periodizing risks a second tendency: this is to code these stages within a narrative of progress or development, against which feminisms in other parts of the world can be judged as advanced or, more typically, backwards (Shih, 2002).

Modern Western feminism was constituted in relation to the abstract individualism that is the basis for social and political inclusion within liberalism. Women have been excluded from many of the supposedly universal norms and claims of liberalism, but have used these norms to struggle for inclusion within them. Insofar as they have shared this experience of exclusion with other social groups, this has offered grounds for alliances. Nonetheless, Western feminism has been criticized for its own exclusions, concealed by its universalizing claims about women’s experience. Criticisms of feminism as white, middle-class, heterosexist and Western were prominent in the 1980s and 1990s, and have led to attempts to understand both the specificity and diversity of women’s experiences. It is not simply that women’s experiences differ depending on other aspects of their social locations; feminism as a political movement takes a different trajectory in different places, depending on how it articulates with other political struggles. In the Philippines, as one example, the ‘second wave’ of women’s liberation dating from 1970 was closely articulated with the nationalist struggle against the collusion between US imperialists and landlord–comprador–bureaucrat capitalist allies within the Philippines (West, 1992). As Morris (2006) writes: ‘Politics’ is irreducibly plural . . . What I have in mind is not simply the diversity of [feminist] groups, movements and “positions” that can be mapped as active at any given time around the world, but rather the intrinsically dynamic, unpredictably complex and consequential nature of political struggle itself; in failing as well as in succeeding, political practices alter the contexts in which they occur . . . [W]e have little to gain from polemically reducing our vision to one project . . . We have too rich a past from which to learn, and too much to do in the future.’ But this also means that the translatability across these myriad feminist struggles can no longer be taken for granted, and that Western feminists must ‘stop positing themselves as objects of mimesis’ (Shih, 2002, p. 116) and do the hard work of fully contextualizing the specificity of feminist social movements in particular times and places.

Feminism has always been a spatial practice: to disrupt traditional organizations of space, to forge productive dislocations and to reconfigure conventions of scale: ‘The dichotomy between the private and the public is central to almost two centuries of feminist writing and political struggle; it is, ultimately, what the feminist movement is about’ (Pateman, 1989, p. 118: see also PRIVATE AND PUBLIC SPHERES). The feminist slogan, ‘the personal is the political’, expresses a refusal to accept both conventional boundaries between public and private, and scalar distinctions between the body and spaces of politics (see FEMINIST GEOGRAPHIES).

The term ‘postfeminist’ emerged in the 1990s, in part to signal differences among women, the fluidity of gender categories and the challenges of building a social movement through the singular identification as women. But there are many options for reformulating feminism in terms other than postfeminism, for instance, as transnational, transversal, as a solidarity movement articulated through obligations of justice rooted in the interdependencies of material conditions in specific places, or as ‘an empty signifier’ that gathers struggles over the production of difference – through political struggle rather than identification (Pratt, 2004). It certainly would be a mistake to assume that feminist struggles have been won. Although women make up roughly half the labour force in many countries, the majority of women in most countries continue to work in traditionally female jobs, for significantly lower wages than men. Reproductive rights won through second-wave feminist activism are under attack in the USA, and the division of domestic labour is largely unchanged in many countries. The devolution of care under neo-liberalism has added to women’s work responsibilities at home, and the increasing militarization of daily life (cf. MILITARISM) in many countries has led to re-masculinization and intensified regulation of heteronormativity.

feminist geographies These geographies focus on how gender and geographies are mutually produced and transformed, and the ways in which gender differentiation and HETERNORMATIVITY permeate social life, and are interwoven with and naturalize other categorical distinctions. The tradition dates from the mid-1970s, drawing inspiration from women’s movements of the 1960s (see FEMINISM); it is both a sub-field and a force that has reshaped
the entire discipline. It now has a considerable institutional presence: the journal *Gender, Place and Culture* has been published since 1994 (a series of excellent reviews of sub-areas within feminist geography appeared throughout 2003 and 2004 to mark the journal’s tenth anniversary); there are over 12 titles in the Routledge International Studies of Women and Place series; regular progress reports of feminist geography appear in *Progress in Human Geography and Urban Geography*; and there are a good number of textbooks targeted to varying levels of undergraduate and (post)graduate students (e.g. Domosh and Seager, 2001; Jones III, Nast and Roberts, 1997; McDowell and Sharpe, 1997; Moss, 2002; Sharpe, Browne and Thien, 2004; Pratt, 2004), along with several key reference texts, including *A companion to feminist geography* (Nelson and Seager, 2005), a *Feminist glossary of human geography* (McDowell and Sharpe, 1999) and *The atlas of women* (Seager, 2003a). Although there are distinguishing strands, some common tendencies cut across all feminist geographies:

(1) They are critical, not only of gender oppression and various manifestations of heteronormativity in society, but of the myriad ways that these are reproduced in geographical knowledge. There is now a comprehensive critique of geographical traditions; for example, *political geography* (Staeheli, Kofman and Peake, 2004); *historical geography* (Domosh, 1991); *humanistic geography* (Rose, 1993); *geographies of modernity and postmodernity* (Deutsche, 1991); and more recent literatures on *transnationalism* (Mitchell, 1997) and *globalization* (Nagar, Lawson, McDowell and Hanson, 2002). Rose (1993) extends her critique to the discipline as a whole, cataloguing its various and complementary forms of *masculinism*. What the relationship between feminist geography and the discipline now is and should be remains a matter of debate: some note the lack of impact that more than two decades of vibrant feminist scholarship have had on the discipline, while others problematize the increased exchange of ideas between feminist and other strands of *critical human geography* (for an excellent discussion of the potential for exchange between feminist geographers and *non-representational theory*, see Jacobs and Nash, 2003). Feminist geographers’ relations with the discipline have been framed through notions of ambivalence and the metaphors of paradoxical and in-between space (Bondi, 2004).

(2) Sexism within geographical institutions (in the teaching of geography, the staffing of academic departments, and through the publication process) has been a persistent concern (Monk and Hanson, 1982; Rose, 1993; Bondi, 2004). In the past decade, this has been intertwined with critiques of persistent *racism* in the discipline.

(3) Nelson and Seager (2005, p. 6) position feminist geography as ‘an innately interdisciplinary sub-field’. Within the discipline, feminist geographers practice this tendency by tracing the interconnections between all aspects of life, across the sub-disciplinary boundaries of *economic*, *social*, *political* and *cultural geography*. This entails breaking down boundaries within sub-disciplines as well; for instance, by demonstrating the interdependencies between informal and formal aspects of the *economy* (see *domestic labour*). In an associated way, feminist geographers disrupt conventional notions of *scale*, and move across scales to trace connections between similar processes in different places (Katz, 2001; Nagar, Lawson, McDowell and Hanson, 2002).

(4) Most feminist geographers share a commitment to situating knowledge, the view that interpretations are context-bound and partial, rather than detached and universal (see *action research*, *phallocentrism*, *positionality*, *reflexivity*, *qualitative methods*, *situated knowledge*). This has produced a large literature on feminist *methodologies*, including four journal symposia – Farrow, Moss and Shaw (1995), Hodge (1995) and Nast (1994b) – and two books (Jones III, Nast and Roberts, 1997; Moss, 2002). It has also led to experimental writing, including various modes of *self-reflexivity* (for a critical evaluation of these experiments, see Rose, 1997b), and to efforts to disrupt the individualist author (e.g. the fused subject of Julie Graham and Kathy Gibson as J.K. Gibson-Graham, the Women in Geography Study Group writing collective, and collaborations between academics and community groups).
(5) Feminist geographers tend to emphasize the specificity of processes in particular places. This has been tied to a critique of universalizing, masculinist knowledge claims, and a commitment to agency and an open, transformable future. Certainly, this has been an important strand of feminist geographers’ criticism of masculinist knowledge, but it has been extended to (non-geographical) feminist theory as well (Katz, 2001a). Attending to the particularities of gendered processes in specific places can be an important means of moving beyond highly polarized academic debates and to engage a messier, more nuanced and ambivalent politics (Nagar, Lawson, McDowell and Hanson, 2002; Pratt, 2004).

(6) Feminist knowledge production is typically aligned with a political commitment to social transformation.

Despite these common themes, there is a great deal of variation within feminist geography. Bowlby, Lewis, McDowell and Foord (1989) sketched an influential history of feminist geographies, in which they identified two breaks, one in the late 1970s and the other towards the end of the 1980s (see figure on page 248). The first break was less decisive in the USA, where the influence of the geography of women approach has been stronger (for a more complete map of national variations in feminist geography, see Monk, 1994). There is also a danger that a model of stages will be read as a progress narrative, with later stages interpreted as more progressive than earlier ones. It should be noted, then, that traditions exist simultaneously and there is a great deal of heterogeneity (national and otherwise) within and outside these generalizations.

An important task for feminist geographers has been to make women visible, by developing a geography of women. The goal has been to achieve gender equality; the spatial vision one of integration (Bondi, 2004). Two points have been central: women’s experiences and perceptions often differ from those of (white) men, and the former have restricted access to a range of opportunities, from paid employment to services. This is largely an empirical tradition, loosely influenced by liberal feminism and welfare geography. It has tended to focus on individuals, documenting how women’s roles as caregivers and ‘housewives’, in conjunction with the existing spatial structures, housing design and policy, and patterns of accessibility to transport and other services such as childcare, conspire to constrain women’s access to paid employment and other resources.

An early criticism of the geography of women approach was that gender inequality is typically explained in terms of the concept of gender roles, especially women’s roles as housewives and mothers, in conjunction with some notion of spatial constraint. Foord and Gregson (1986) argued that the concept of gender roles narrows the focus to women (as opposed to male power and the relations between women and men), emerges out of a static social theory, and presents women as victims (as passive recipients of roles). Further, although the geography of women shows how spatial constraint and separation enter into the construction of women’s position, it typically provides a fairly narrow reading of space, conceived almost exclusively as distance, or as transparent, and (potentially) gender-free (Bondi, 2004). In early work in this tradition, insufficient consideration was given to variations in gender relations across places. There has been, however, a very useful planning component to this literature that outlines, for example, efforts to restructure the city so as to reduce gender inequalities and enhance quality of life (e.g. Wekerle and Whitzman, 1995). Both successes and frustrations in attempts to implement some of these reforms have led to critical reconsiderations of the limits of liberal feminism and towards a fuller institutional analysis, confirming Eisenstein’s (1981) point that the practical and theoretical limits of liberalism are frequently discovered – in practice – by liberal feminists themselves.

Socialist feminist geographers reworked Marxian categories and theory to explain the interdependence of geography, gender relations and economic development under capitalism (see Marxist geography). One of the key theoretical debates within socialist feminist geography revolved around the question of how best to articulate gender and class analyses. At its most abstract, the question was addressed in terms of patriarchy and capitalism, and the relative autonomy of the two systems. Socialist feminist geographers first worked primarily at the urban and regional scales; arguably, it is a renewed version of socialist feminist that is now most insistent about the material effects of the globalizing forces of capitalism. At the urban scale, an early focus of Anglo-American feminist geographers was the social and spatial separation of suburban homes from paid employment; this was seen as crucial to the
day-to-day and generational reproduction of workers and the development and continuation of ‘traditional’ gender relations in capitalist societies (MacKenzie and Rose, 1983). Given a feminist commitment to agency, efforts were made to read these processes in non-functionalist terms and as strategies to manage the effects of a capitalist economy (cf. FUNCTIONALISM). For example, MacKenzie and Rose argued that the isolation of women as housewives in suburban locations emerged from the combined influence of working-class household strategies, governmental policy and male power within families and trades unions. Socialist feminist geographers also have been attentive to the ways in which gender relations differ from place to place, and are sedimented within place-specific social and economic relations, in ways that not only reflect but partially determine local economic changes. This argument has been made at urban (Hanson and Pratt, 1995), regional (McDowell and Massey, 1984) and international scales (Pearson, 1986).

Beginning in the late 1980s, many feminist geographers moved away from an exclusive focus on gender and class systems, to consider more expansive geographies of DIFFERENCE (see IDENTITY; RECOGNITION). Feminist geographers were increasingly attentive to the differences in the construction of gender relations across races, ethnicities, ages, (dis)abilities, religions, sexualities and nationalities; to exploitative relations among women who are positioned in varying ways along these multiple axes of difference (see AGEISM; ETHNICITY; HOMOPHOBIA AND HETEROSEXISM; RACE; RACISM; SEXUALITY); and to the ways that gender classification orders the existence not just of men and women, but animals, Commodities, ideas and other entities. Gender is a powerful means of naturalizing difference. They began to draw on a broader range of social, and particularly cultural, theory, including PSYCHOANALYSIS, POST-COLONIALISM, POST-STRUCTURALISM and QUEER THEORY, in order to develop a fuller understanding of how gender relations and identities are shaped and assumed (see SUBJECT FORMATION). This led to fundamental rethinking of the category, GENDER, and attending to the contradictions and possibilities presented by the seeming instability of gender. With a focus on multiple identifications and PERFORMATIVITY, the emphasis shifted from material constraint and spatial entrapment to possibilities beyond fixity. This was articulated in Rose’s (1993) notion of paradoxical space: the sense that the multiplicity and contradistinctiveness of the ways in which we are positioned in space generates possibilities excessive to hegemonic heterosexual norms and spaces (for further thoughts about the ways in which performativity and space are intertwined, see also Gregson and Rose, 2000; Pratt, 2004). Metaphors of multiplicity, mobility and fluidity, of HYBRIDITY and paradoxical, in-between, spaces were immensely popular in the 1990s, including Gibson-Graham’s (2006b [1996]) influential re-theorizing of capitalism and CLASS processes. A considerable amount of writing developed around gendered cultural REPRESENTATION, which extended the focus to imaginative and symbolic spaces (see FILM AND GEOGRAPHY; IMAGINATIVE GEOGRAPHIES; VISION AND VISUALITY). A small but growing number of studies of masculinities (Berg and Longhurst, 2003) began to deliver on the promise of a gender relational approach, by directing the focus away from women to a larger network of heteropatriarchal relations. The influence of identity politics and post-structural theories refocused attention on SEXUALITY and the scale of the BODY.

Nonetheless, new fault lines emerged among feminist geographers. Monk (1994) observed that national differences between American and British geographers diminished as both pursued these new directions, but divisions between feminist geographers located in the global NORTH and global SOUTH increased, an institutional schism that repeats geopolitical ones in troubling ways. By 2006, Ramon-Garcia, Simonsen and Vaiou declared that Anglophone hegemony within institutionalized feminist geography was not improving; on the contrary, it was getting worse. And by the mid-1990s, cautionary reactions to a focus on MOBILITY, identity and difference suggested the need to re-invigorate links with a renewed socialist feminism.

To a considerable extent this has happened, and a fourth strand of feminist geography could be called ‘transversal’ feminist geography. Connections are being drawn in many directions. Seager (2003b) reviews fruits of ‘boundary breakdown’ within feminist POLITICAL ECOLOGY AND ANIMAL geography. The latter traces structures of oppression across gender, race, class and species, as well as exposing gendered assumptions that underlie human relations to non-humans and what is conceived as NATURE. The lessons from the debates about difference in the 1990s have
been learnt, and a defining characteristic of feminist animal rights analyses (as compared to those of ‘mainstream’ animal rights advocates) is the tendency to theorize an ethics of care without erasing the differences between humans and non-humans. Feminist geographers continue to focus on the body, but are possibly more effective in theorizing the body at a multiplicity of ‘scales’ and institutional sites, especially in relation to the economy (Wright, 1999a) and the state. Feminist geographers are tending more and more to develop their analyses beyond their national boundaries, to understand the connections between processes and lives in the global North and global South (Katz, 2001a; Nagar, Lawson, McDowell and Hanson, 2002; Pratt, 2004). As part of this, feminist geographers are re-inventing critical geopolitics to develop a politics of security that includes the civilian body and decentres a focus on state security (Hyndman, 2005). State violence; the rape and torture of men and civilian women as technologies of war; the production of ‘the monster’, ‘the fag’ and ‘the terrorist’ as figures of surveillance and criminalization (Puar and Rai, 2002); the re-masculinization and militarization of daily life; the impact of neo-liberal policies on the global gender division of labour – these are themes that press for attention in our contemporary world.

**feminist geographies**  
"Interwoven strands of feminist geography"
fertility Reproductive performance, or the number of live births. Along with mortality and migration, it is one of the three components of the balancing equation and, as such, an important influence upon the growth, composition and distribution of populations (see demography). Unlike mortality and morbidity, which have been the subject of long-standing interest in medical geography and geographies of health and health care, and migration, similarly investigated in population geography, fertility (and fecundity) continues to receive scant attention within geography (Boyle, 2003), despite such trends as the emergence of negative population growth rates fuelled by low fertility, increasingly complex household forms and a growing emphasis upon social reproduction in the discipline.

Research on geographical variations in fertility makes use of two types of measures. Period measures focus on events that occur between a starting and ending date, and include the crude birth rate (the number of births in a year for every 1,000 persons in a population). Cohort measures focus on events that occur to a particular group of individuals, such as those born or married in the same year, and include the total fertility rate, which represents the number of live births that a woman currently aged 15 would expect by the time she reaches age 49 and assuming that current age-specific fertility rates remain constant. The fact that a large number of countries exhibit total fertility rates well below the replacement level of 2.1 has stimulated debate on the fertility and demographic transition in particular, and the changing role of children and adults in society more generally (Greenhalgh, 1995; Waldorf and Franklin, 2002).

Research on the politics of reproduction explores discourses surrounding family planning, reproductive health and reproductive rights movements, particularly as they impacted upon policy recommendations from successive meetings of the International Conference for Population and Development, and the geographical nature of social constructions surrounding, for example, teen pregnancy, child-birth and maternal mortality (Fernandez-Kelly, 1994; Grimes, 1999; Underhill-Sem, 2001). Feudalism A term used in the analysis of pre-capitalist societies, especially those of medieval Europe, but also Japan under the rule of warlords from the twelfth to the nineteenth centuries. Feudalism has a wide range of meanings, from a legal focus on the military obligations imposed through the concept of a fief (see below) to a more comprehensive, quintessentially political and economic characterization of feudalism as a specific mode of production or social formation. The increasing scope of the definition owes much to a growing interest in comparative history and, in particular, to studies of the geographically variable relationships between the decline of feudalism and the rise of agrarian capitalism (Hilton, 1976; Kula, 1976; Martin, 1983; Dodgshon, 1987; Glennie, 1987). But this has also prompted a fear that, outside history and historical geography, “feudalism” seems to have become a general catch-all term denoting almost anything in the pre-modern period; it is as though all societal relationships, economies and politics of the medieval period can be defined simply by this legal term that describes the action of lords collecting a surplus through a sort of military protection racket (Harvey, 2003b, p. 152). Such a prospect has been complicated by more recent analyses that claim to identify a resurgent feudalism within late modernity, a sort of ‘medieval modernity’ predicted on a particular combination of fiefdom and freedom and the production of fractured and competing sovereignties associated with the aggressive advance of neo-liberalism in both the global north (alSayyad and Roy, 2006; Zafirovska, 2007) and the south (cf. Murray, 2006).

In its classical sense, feudalism comprises two distinct social groups. The first is a group of direct producers (broadly peasants) who maintain direct, which is to say non-market, access to the means of production (land, tools, seed-corn and livestock) even though they may not own them (especially land). This group is subject to politico-legal domination by a second group of social superiors, who form a status hierarchy headed by a monarch or sovereign (see sovereign power). The sovereign ultimately owns all the land, but land tenure is effectively decentralized through grants of land to feudal lords in return for their political and military support. In such a system, social relations of production are thus not defined primarily through markets, as in capitalism, and the means by which a surplus is extracted from the direct producers is different from systems like slavery.

The key social relationships in European feudalism were vassalage and serfdom. Vassalage was an intra-elite relationship by
which a subordinate (vassal) held rather than owned landed property, the ‘fief’ (Latin feudum, feodium, hence feudalism) from a lord, ultimately the sovereign, in return for military service required by the sovereign. The sovereign’s vassals were tenants-in-chief, who in turn ‘subinfeudated’ their estates to raise their own military service. Thus a hierarchy of feudal tenants came to hold estates of various sizes, composed of territorial jurisdictions called manors, in what Anderson (1974, pp. 148–9) described as a complex ‘parcellization’ of sovereignty.

Serfdom was the legal subjection of peasant tenants to lords through the latter’s manorial jurisdictions, of which unfree tenants were legally held to be part. Dependent peasant tenants held land from their lord in return for varying combinations of services in kind, especially labour services on the lord’s own land within the manor (the demesne) and money rents. The legal dependence of peasant tenants enabled feudal lords both to extract higher than market rents from their tenants and also to impose a range of other dues and exactions, including duties on death and licenses to marry, to migrate or to brew ale. Peasant tenants were fined at a manorial court if these activities were undertaken without appropriate licenses, and courts also exercised a degree of moral regulation.

The level of rents and dues was set more by lords’ income requirements than by market forces, although lords gained from the latter as population growth made land scarce relative to labour. Seigneurial income requirements progressively increased as lords competed for political status through conspicuous progressions in territorial possessions. Moreover, since feudal lords could raise income from intensified surplus-extraction, they were comparatively indifferent to innovations to raise agricultural productivity. These claims have important implications for the explanatory value of the geography of manorialism (estate size and fragmentation, seigneurial character) and of the lord–tenant struggle in accounting for geographical variations in population density, agricultural systems and productivity, and standards of living (Hilton, 1973; Hallam, 1989; Campbell, 1990, 1991; Dyer, 1993). As lordly extraction intensified, and medieval European populations grew (for reasons as yet imperfectly understood), feudal society exhibited certain crisis tendencies, because the surplus removal process failed to generate any significant feedback into the productive capacity of agriculture through investment. A crisis of social reproduction was inevitable since:

1. Production for the market and the stimulus of competition only affected a very narrow sector of the economy.
2. Agricultural and industrial production were based on the household unit, and the profits of small peasant and small artisan enterprises were taken by landowners and usurers.
3. The social structure and the habits of the landed nobility did not permit accumulation for investment for the extension for production (Hilton, 1985).

Hilton’s work remains an important demonstration that towns and trade were integral to feudal economies, not ‘non-feudal islands in feudal seas’, exogenous factors that undermined feudal social relations (cf. Pirenne thesis). But recent studies have paid more attention to the extent of commercialization within medieval agrarian economies and its impact on geographies of manorialism (Power and Campbell, 1992; Campbell, 1995). While debate continues on the importance to medieval agrarian contraction of excessive surplus-extraction (see Brenner thesis) and ecological frailties (see Postan thesis), there has been a general move towards more sophisticated theorizations that broaden analysis of feudal society beyond property relations. Greater attention has been paid to accumulation and differentiation within the class of direct producers (Poos, 1991; Razi and Smith, 1996a). Important developments in social technologies changed the geographical structuring of feudal society. Over time, status came to be increasingly embodied in property rather than interpersonal relations. Notable geographical components stemmed from this shift, including new legal, fiscal and administrative technologies to control time and space (Bean, 1989; Biddick, 1990; Clanchy, 1993). Finally, certain social continuities across the feudalism–capitalism transition, especially in the functioning of geodemographic and cultural systems, have received serious attention (Poos, 1991; McIntosh, 1998).

Suggested reading

field system The fields and other agricultural resource elements, such as wastes and commons, of a community or communities that may be regarded as functioning as an agrarian and social system (Gray, 1915; Dodgshon, 1980). In a more specific sense,
the term can be applied to early patterns of landholding and husbandry that entwined groups of cultivators into communities of mutual or common interests through their use of landed resources. In studies of the historical geography of Europe, particular attention has focused on the manner in which the intermixture of land between landholders has taken the form of strips or parcels. Other themes that loom large in defining such systems are the extent to which the system possessed a communally regulated system of cropping, or the degree to which arable cultivators possessed rights in common over the cultivated area after harvest. Analysis of such systems has also been linked to the nature of land tenure and the extent to which individual ownership of land prevailed. Debates surround the extent to which communal systems of tenure and their associated field systems are seen invariably to predate those based upon enclosed fields held in severally. In considering open field systems, emphasis might be placed on the way in which individual's holdings or strips of land were distributed over larger fields subject to rule-based cropping practices that were generated internally by the cultivators themselves or imposed by outside agencies such as landlords, or formed a means of risk minimization to ensure that cultivators had lands under different crops on variable soil types, or whether they were incompatible with effective and efficient agrarian management. Such systems have formed the basis of debates in political economy about the benefits of individual over communal tenure. The debate over the enclosure of open field systems into enclosed fields and associated scattered free-standing farms managed without reference to communal rules and regulations has played a prominent role in the timing of the agricultural revolution (Allen, 1992). Other scholars have focused on the supposed social consequences that may have flowed from enclosure and how the removal of access to communal grazing, post-harvest gleaning and the right to collect fuel and other food resources from commons turned smallholder peasants into rural proletarians (Neeson, 1993).

fieldwork A means of gathering data that involves the researcher in direct engagement with the material world. Once based in the enlightenment assumption that 'reality' was out there available for straightforward apprehension, fieldwork is now recognized as a more complicated mode of learning that produces situated knowledge about people, processes and places. While this perspective may be seen as a hindrance in positivist approaches to human geographical research that seek to neutralize the researcher and aspire to statistical generalizations, many now recognize the strength of self-reflexivity and the necessarily partial nature of the information collected. The two modes of scholarship endure in fieldwork, and the epistemological tensions between them can be daunting (e.g. Sundberg, 2003: see also epistemology).

Field research has a long history in human geography. Since antiquity, much of it has been associated with imperial projects, and thus involved exploration, mapping and the taxonomic categorization of resources – animal, plant, mineral and human. But fieldwork is also a means to examine the relationships between people and their environments, the material social practices of place-making, the productions of nature and the sedimentations of these relationships in diverse historical geographies. Fieldwork in this regard has had a more ambiguous and contested relationship with the discipline – pitting observational against theoretical knowledge and sometimes challenging received ways of knowing (cf. Driver, 2000). Its multiple strands include the 'stout boots' tradition of British geography and Sauerian cultural geography in the USA (Delyser and Starrs, 2001; cf. Withers and Finnegan, 2003). Evolving from a natural history tradition, wherein physical evidence was collected in and from the environment, fieldwork of this nature focuses on landscapes as evidence of differentiated, sequential and uneven human occupancy; seeking relationships and patterns in their production and persistence. Many of the field methods associated with these traditions are rooted in observation. The taken-for-grantedness of seeing as well as its reliance on unmarked 'vantage points' has been subjected to a thorough critique as masculinist, because its claims to objectivity rest on unstated hierarchies, detached observers and distancing assumed adequate to reveal hidden dimensions of the scene (Barnes and Gregory, 1997b; Rose, 1997b; Sundberg, 2003). Given these concerns and other limits of traditional approaches to fieldwork, including its interested nature, unsustainable assumptions regarding the distinction between nature and culture, and the tendency to focus on visual
rather than more dynamic, relational and contested forms of evidence, many fieldwork practitioners developed a more critical stance to their work. Feminist geographers (see FEMINIST GEOGRAPHIES) were key in this intervention, examining the politics of REPRESENTATION that percolate through fieldwork, scrutinizing the uneven power relations that propel it and calling its epistemological claims into question (Rose, 1993; Professional Geographer, 1994; Sundberg, 2003).

Engaging in fieldwork of this kind raises the question of what constitutes the field. The field, as Felix Driver (2000, p. 267) reminds us, ‘is not just “there”; it is produced and reproduced through both physical movement across a landscape and other sorts of cultural work in a variety of sites’. It is also the effect of discursive and spatial practices that mark it as a site of enquiry ‘that is necessarily artificial in its separations from geographical SPACE and the flow of time’ (Katz, 1994, p. 67). These distinctions and the sorts of knowledge derived from them are constituted through embodied practices such as travel, residence, visiting, conversation, observing, eating, smelling, listening and various (re)presentations of self. The field and the fieldworker are co-constructions, and the knowledge produced between them reflects the materiality and mutability of this relationship. Scholars have addressed the various and multiple connotations of movement among fields – the constitution of a field site, the way in which the site and the sorts of knowledge produced there are constructed in one’s disciplinary field, and the uneven valences of power that energize and can confound the multiple translations – spatial, linguistic, and practical – of fieldwork (e.g. Professional Geographer, 1994; Pluciennik and Drew, 2000; Saunders, 2001). Questions of power affect such things as negotiating access, whether and how to conduct research in areas of CONFLICT and VIOLENCE, determining what kinds of knowledge can be shared and with whom, figuring out what cannot be said and making sense of the silences, and representing oneself in ‘the field’ and the field to one’s audience.

The METHODOLOGY of fieldwork is capacious and eclectic, encompassing quantitative and qualitative strategies of data collection. While fieldwork is commonly associated with CASE STUDY methodologies and ETHNOGRAPHIC research, it also includes survey research, broad observational studies, mapping and measurement techniques. Among the research methods associated with fieldwork in human geography are all manner of field observation, including PARTICIPANT OBSERVATION, landscape assessment and site observation; oral techniques such as casual conversation, unstructured and structured interviews, FOCUS GROUP INTERVIEWS, oral histories and environmental autobiographies; survey and census techniques (see SURVEY ANALYSIS); digging through, collecting, sorting, classifying and interpreting records, whether in the ground, in place or in archives; measurement and mapping activities; and documenting what is observed and experienced in a variety of ways, including written, photographic, cartographic, aural and artistic means. Recent investigations of fieldwork have addressed issues such as the embodiment of the fieldworker (see BODY), bringing companions to the field, sexual relations in the field, and the ETHICS and implications of dishonesty and misrepresentation in fieldwork. As these concerns suggest, fieldwork produces knowledge that is avowedly situated, and its validity resides both in that recognition and in the disciplined REFLEXIVITY that enables researchers to expose their practices and question their findings.

FILM

An inherently spatial technology through which fragments of IMAGES and sounds from different times and spaces are reassembled, and then transported to audiences in many different locations. It can be studied as a mobile cultural REPRESENTATION, a public gathering (at the cinema or movie theatre), a political opportunity, a mode of GOVERNANCE and an economic activity. The boundaries of film now blur into television, video, MUSIC and amusement park culture.

Much film analysis focuses on the film itself – for example, the narrative structure, the sets, camera shots and editing – and it can be a means of studying how dominant social and geopolitical understandings and anxieties are expressed, produced, transmitted and resisted. US noir films of the 1940s and 1950s, for instance, have been interpreted as expressions of geopolitical and social anxieties: about nuclear WAR, the MIGRATION of southern African-Americans to northern cities, and relations between women and men. The geographies scripted into noir films (e.g. the dark and foreboding city) express and fuel these anxieties (Farish, 2005). Alternatively, as a...
mode of storytelling and site-seeing, film can be a medium for travelling across and juxtaposing different worlds, and rupturing dominant narratives about place; Taylor (2000) assesses the ways in which The Coolboroo Club, a film made by and about Perth’s Nyungah community (an aboriginal community that was banned from entering the central metropolitan area in the 1930s and 1940s), draws on aboriginal memories to supplement and disrupt hegemonic white history of ‘sunny’ Perth. Because film is such a good vehicle to think with and about dominant and resistant social meanings, it can be an excellent pedagogical tool; the Journal of Latin American Geography instituted an extensive film reviews section for this purpose in 2005, and Cresswell (2000) chronicles his use of the film, Falling Down, to generate nuanced classroom discussion of resistance.

Film is more than another medium for storytelling, and a long tradition of cultural criticism and avant-garde films make larger claims about the capacity of film to stimulate novel sense experiences and generate critical thought. Close-up shots, cross-cutting, slow motion and flickering effects, montages of images that juxtapose the far and near, the present and the past, and spaces that are ordinarily segregated or otherwise kept apart – these are some of the cinematic techniques that can be used to dis-order and re-order space and time, and shock the senses. Walter Benjamin (1978) theorized film’s potential to de-naturalize social relations and social space; Deleuze (2001) wrote of the promise of ‘pure optical’ situations in (particularly neo-realist) film: to release the viewer from linear cause-and-effect perceptions and bring the senses into a new relation with time and thought. Both theorists draw connections between film and the CITY: the modern city in the case of the former, the rupture forced by devastated post-Second World War European cities for the latter. It is not just theorists who have appreciated the transformational potential of film; Olund (2006) argues that urban reformers in the early-twentieth-century USA embraced some similar ideas about the ways in which film works on sense perception, and recognized film as a powerful tool for governance, especially for assimilating immigrants into middle-class norms of whiteness.

Aitken and Zonn speculated that geographers have been slow to make a serious study of film because of ‘the geographer’s traditional emphasis on the material conditions of social life wherein representation is subsidiary to “physical reality”’ (1994, p. 5). Even so, there are rich opportunities for investigating the play between filmic representations and concrete spaces. Analysing the Nigerian film industry, Marston, Woodward and Jones (2007) argue that the distinctive aesthetic of ‘Nollywood’ films (long sequences with extensive and repetitive dialogue, and little or no action) emerges out of local material circumstances of small budgets, fast shooting schedules, small crews and reliance on readily available locations. At the same time, filmic representations have material consequences. The negative portrayal of the inner city in post-Second World War Hollywood film, it has been argued, created a popular disposition in the USA for massive demolition of inner-city neighbourhoods and urban restructuring.

The film Chinatown, a fictionalized rendition of political corruption, personal greed, capitalist development and water policy in Los Angeles, is now understood to be and deployed as the historical ‘truth’ by environmental groups who wish to stop contemporary dam proposals (both case studies are found in Sheil and Fitzmaurice, 2001). The Hollywood film Entrapment created an uproar in Malaysia when it was released in 1999, because images of the Petronas Towers in Kuala Lumpur were spliced with those of a distant shanty town, to suggest that the two geographies lie side by side. This was at odds with the impression that city boosters wished to project, that of Kuala Lumpur as a clean, modernizing ‘world class’ city. As the government’s Information Minister complained, ‘the whole world will come to believe that the scenery they saw in the movie . . . is real’ (cited in Bunnell, 2004, p. 300). Alternatively, popular films can generate informal and formal tourism spin-offs, when appreciative fans seek out the sites used in movie scenes. In many cities, the film industry is a major economic activity, certainly in cities such as Los Angeles (Scott, 2005a), Mumbai and Hong Kong, but in many other cities as well, whether as a location or through the business of film festivals. The geographies of film production and reception have become increasingly complex: the transnational nature of many productions complicates debates about non-Hollywood ‘national’ cinemas (Acland, 2003); and diasporic communities generate demand for films produced outside of the USA, whilst the heavy dependence of the US entertainment industry upon international markets disrupts simplistic assumptions about the one-way, global transmission of US culture.
FILTERING

The cinema itself is a PUBLIC SPACE, which some have argued was particularly important for women and immigrants in the early-twentieth-century US city; Hansen understands it to be a site for the formation of a counter-public sphere. Much of this has changed with new technologies of home videos and DVDs, but Hansen (1995) has been loathe to understand these new technologies as simply leading to the diminishment of cinema as counter-public sphere. She speculates that contemporary film viewers, now used to having control over their viewing at home, are more active than they were in the classical Hollywood period of film spectatorship. Certainly the material conditions of viewing film are changing. In North America through the 1990s, there was a dramatic increase in the number of screens constructed and a simultaneous reduction in the number of theatres, reflecting the construction of multiplexes, facilities that with multiple screens, typically located in the SUBURBS. These multiplex amusement spaces generate a different timing and spacing of film spectatorship (Acland, 2003).

Film (and video) is not simply an object, but a tool for analysis. Pryke (2002, p. 473) calls up Lefebvre’s notion of RHYTHMANALYSIS to introduce his video and audio montage of urban redevelopment of Potsdamer Platz in Berlin (http://www.open.ac.uk/socialsciences/geography/research/berlin/). Concerns with PERFORMANCE and life that exceeds DISCOURSE (see NON-REPRESENTATIONAL THEORY) have fuelled interest in using film and video as a means of representation, and electronic journals such as ACME now allow the blending of TEXT and video (e.g. Pratt and Kirby, 2003). Media literacy and video production training has been a useful methodological strategy in ACTION RESEARCH.

filtering A process whereby housing value and status declines over time while HOUSEHOLDS gain access to increasingly higher-quality dwellings. The theory emphasizes MARKET forces in, and identifies triggers for, changes in the allocation of housing (see HOUSING STUDIES; INVASION AND SUCCESSION). The literature includes numerous refinements to filtering MODELS (Galster, 1996) and also strong critiques of the normative element in filtering theory, which tends to legitimate laissez-faire approaches to housing provision in which demand from wealthier households for new housing is expected to open up better housing for lower-income groups (Gray and Boddy, 1979).

financial exclusion The process by which people of poor and moderate incomes are directly and indirectly excluded from the formal financial system and denied access to mainstream retail financial services (see also MONEY AND FINANCE). Financial exclusion plays an active part in the geographical production of POVERTY, because those who experience difficulty in gaining access to formal financial services tend to belong to disadvantaged social groups undergoing multiple forms of social deprivation (Leyshon and Thrift, 1997).

Access to mainstream financial services within contemporary societies is important because many economic exchanges are now mediated through financial institutions through direct transfers between accounts. Without access to the financial system, individuals and HOUSEHOLDS may find it more difficult and expensive to pay bills, while the lack of access to products such as insurance denies them the opportunity to shield against risk. In this sense, having access to a full range of financial services at a competitive price may be taken to indicate ‘financial citizenship’. In large parts of the developing world, the majority of the population may lack financial citizenship, whereas in industrialized countries such as the USA and the UK it is estimated that around 10 per cent of the population is financially excluded (cf. CITIZENSHIP).

The process of financial exclusion is a product of a broader bifurcation of the MARKET for retail financial services. Socio-technologies such as credit scoring systems sort ‘prime’ from ‘sub-prime’ customers on behalf of financial institutions. Prime financial markets are made up of individuals and households that possess socio-economic and geodemographic profiles that make them targets of the marketing and financial strategies of retail financial services firms. These middle- and high-income customers are actively pursued by retail financial services firms, and may be described as the financially ‘super-included’, benefiting from intense competition between institutions for their business. One of the drivers of this strategy is the tendency
towards the securitization of retail financial products, whereby lenders aggregate the loans made to low-risk customers and sell them to investors in international securities markets (Dymski, 2005). Sub-prime customers, meanwhile, have low to moderate incomes and/or financial assets, and are either excluded from mainstream financial marketing campaigns for new products or are denied access to services if they apply.

The geography of prime and sub-prime financial markets follows established geographies of income and wealth. Thus, for the most part, prime retail financial customers may be found in affluent urban and suburban areas, whereas sub-prime markets are concentrated in areas of low and moderate income, typically in inner-city areas (and, in the UK, at least, on public-sector housing estates). In the absence of mainstream financial services, which continue to close branches in such areas, a host of specialist sub-prime or ‘fringe’ retail financial institutions ply their trade. They provide similar services to the mainstream, but at a much higher cost. It is now possible to identify pronounced financial ecologies, made up of distinctive combinations of markets, customers and institutions (Leyshon, Burton, Knights, Alferoff and Signoretti, 2004). Public policies to counter the problems of financial exclusion were initiated with increased vigour in the late 1990s (Marshall, 2004), and the explosive growth of ‘predatory lending’ in sub-prime markets was a key factor in the global financial crisis that detonated in 2008.

**Fiscal crisis** A fiscal crisis occurs when the revenue raised by the state is insufficient to cover the cost of its activities. All governments experience short-term financial problems as a result of routine fluctuations in tax revenues and public expenditure. The term ‘fiscal crisis’ is usually reserved for a more serious shortfall in the state’s financial position arising from structural or systematic imbalances between the cost of providing public services and social security payments and the ability of the state to finance them through taxation.

According to O’Connor (1973), a tendency towards fiscal crisis is a logical outcome of the contradictory character of the state under capitalism. O’Connor argues that the state has two main functions within capitalism: to promote accumulation by private capital, and to ensure the legitimacy of this process among the population. To do the former, the state needs to make investments in economic infrastructure (e.g. roads, energy supply networks, the central bank), systems of regulation (e.g. to ensure the orderly functioning of market exchange; cf. Regulation theory) and the maintenance of a productive labour force (e.g. by providing education). To do the latter, the state seeks to promote social integration through expenditure on the welfare state and the maintenance of law and order.

O’Connor’s analysis suggests that with the emergence of the monopoly form of capitalism in which markets are dominated by a small number of large corporations, an increasing proportion of the costs of investment must be met by the state, while expenditure on social problems also grows. This requires the state to seek to raise extra revenue from taxation, which has the effect of discouraging private investment, thereby reducing the tax base and exacerbating the problem. This can result in a fiscal crisis as the state’s revenue-raising capacity is reduced at the same time as demands for increased state expenditure grow.

The state may seek to resolve the crisis by trying to reduce public expenditure as a proportion of the economy. However, this may result in a crisis of legitimation as welfare expenditure is cut. In some cases, however, powerful states (notably the USA) have been able to sustain very large budget deficits for extended periods and to stave off fiscal crises by borrowing from overseas. In 2006, approximately one-quarter of the total US public debt of $8,500 billion was held by foreign governments and international investors.

A tendency to fiscal crisis may be spatially differentiated, particularly where local governments have autonomous revenue-raising capacities. In the 1970s and 1980s, many US cities faced serious fiscal problems as manufacturing industry declined and higher-income residents moved out to the suburbs (see Fiscal Migration). In 1975, New York City avoided bankruptcy only after the federal government intervened. Subsequently, many local governments have faced budgetary constraints as a result of restrictions imposed by the central state or because of poor credit ratings imposed by increasingly influential private rating agencies (Hackworth, 2006).
users will move to a local government administration that optimizes their tax and services preferences, trading off the costs of paying for public services through taxation against sacrifices in their ability to consume private services. The model has been used to explore the geographical consequences of distributed and competitive local government administrative structures (e.g. Davies, 1982). The process also operates at an international level, and underlies the creation of offshore financial centres, tax havens and export processing zones, all of which attract international capital investment partly through fiscal incentives that include tax holidays and other inducements. Al.

flâneur/flânerie The flâneur is associated with aimless urban wandering and observing, especially in nineteenth-century Paris, where it took its first steps. Yet the figure has also walked further afield, as it has been taken up more widely in social, cultural and urban studies as ‘an emblematic representative of modernity and the personification of contemporary urbanity’ (Ferguson, 1994, p. 22). Despite becoming a common motif, the flâneur and activities of flânerie remain elusive and resist easy definition, although they usually involve a solitary and anonymous male, with the emphasis falling variously on strolling, idling, watching, writing, artistic creativity and detection. Many commentators suggest that it is most productively seen as a mythological figure, a strategy of representation, and thus a social construction within discourse more than a sociological reality.

First referenced in 1806, the flâneur received its most famous articulation in the writings of Charles Baudelaire, for whom it was a ‘modern hero’ and passionate spectator who derived poetic meaning from an immersion in the city, in the fleeting movement and electrical charge of its crowd. Baudelaire’s account played an important role in Walter Benjamin’s investigations of Paris as ‘capital of the nineteenth century’, and in his attempts to decipher the phantasmagorias of urban modernity. In these texts, the increasing commodification and rationalization of the city along with the decline of the arcades meant that the flâneur was already becoming a displaced and bygone figure. Benjamin’s writings have remained a key source for subsequent interest in the flâneur, with some critics viewing Benjamin’s own approach as being akin to flânerie in its mode of reading metropolitan spaces through attending to urban fragments and signs. There have also been multiple reinventions of flânerie in the arts, cultural practice and urban studies through recent interest in other forms of urban walking (see Urban Exploration).

Feminist critics have emphasized the exclusivity of flânerie, arguing that a female equivalent – the flâneuse – was rendered impossible by the ideologies and sexual divisions of nineteenth- and early-twentieth-century cities that constrained anonymous and unaccompanied movement by women. The practice of flânerie itself, so it is argued, was structured around a male gaze. However, critical elaborations have since questioned the extent of the exclusion of women from the public realm, revealing the intersections between public and private, and have also argued that the flâneur was a more insecure and marginal figure than is often supposed (Wilson, 1991). Writers have further traced out the possibilities for female flânerie through the development of department stores, through writing and literary texts and through early cinema, which enabled a mobile urban gaze from within the safety and respectability of a film audience.

Such studies have led to re-evaluations of the (in)visibility of the flâneuse (D’Souza and McDonough, 2006). Dissenting voices nevertheless remain, with Janet Wolff arguing that the problem with the flâneur lies less in its exclusivity than in the centrality it has been accorded in urban and cultural studies of modernity, and in the consequent occlusion of female experiences. She therefore calls for the flâneur’s ‘retirement’ from centre stage and for attention to turn instead to the ‘micro-practices of urban living, and the very specific ways in which women negotiate the modern city’. In the process, she claims, questions of female flânerie lose importance and ‘women become entirely visible in their own particular practices and experiences’ (Wolff, 2006, p. 28).

Flexible accumulation A regime of accumulation emphasizing diversity and differentiation rather than the standardization associated with Fordist modes (see Fordism) of accumulation. Flexible accumulation requires workers, machinery and manufacturing techniques that can quickly and regularly innovate and adapt to changes in consumer tastes, thus generating profit through economies of scale. As Harvey (1999 [1982]) points
out, the (re-)emergence of flexibility as a dominant regime of accumulation in the late 1970s and 1980s was associated with instability in the economies of developed countries and competition from third world industrializing nations that could mass-produce standardized goods cheaply. For McDowell (1991), it was also a change in the basic societal conditions – such as the increasing disappearance of the nuclear family as the standard domestic unit and the increasing entrance of women into the labour force – that challenged the many of the ideals underlying the Fordist regime of accumulation and led to the growth in importance of flexible accumulation. However, Gertler (1988) cautions against assuming that means that flexible accumulation replaced Fordist modes of accumulation; rather, flexible accumulation re-emerged in this period as the dominant regime in developed countries (see also Norcliffe, 1997).

For geographers, flexible accumulation is associated with what Storper (1997b) refers to as the ‘resurgence of the region’ in industrial geography. Because of the need for continuous innovation and rapid adaptation to changes in consumer demands, trusting relationships with numerous suppliers who can provide components just in time and expertise that facilitates innovation is important. At the same time, flexible accumulation requires producers to have access to a pool of skilled labour, something that can often be found in specialized regions or clusters, where complementary industries exist. Examples include Motorsport Valley in Oxfordshire, UK (Henry and Pinch, 2001), Silicon Valley in California, USA (Saxenian, 1994), and Santa Croche in Italy (specializing in leather production: see Amin, 1989). flows A name for movements between relatively fixed nodes in networks, flows can be of commodities, money, people, energy or even ideas. In the 1980s and 1990s, a series of developments in both theory and global relations made reference to ‘flows’ increasingly common in a wide range of academic fields. In theoretical arguments, long-standing Marxist concerns with explaining economic processes in terms of the circuit of capital came to be critically supplemented with Foucauldian and other post-structuralist arguments about the need to understand identity and power in terms of the flow of power through social relations. Though it is often forgotten, the jargon of deterritorialization developed by the French–Italian philosophical duo Deleuze and Guattari (1983) was just such an epistemological intervention: not an empirical claim about the geography of postmodernity, but a postmodern psychoanalytical argument about the need to follow diverse flows of desire and thereby critique containerized concepts of the human psyche in modern ego-psychoanalysis (cf. psychoanalytic theory). More generally, the critical import of treating power in terms of micro-flows did have implications for theories of space (see production of space). Just as Marxist geography had challenged absolutist and fixed assumptions about space in economics by exploring capital as value in motion in global and urban landscapes (Harvey, 1999 [1982]), so in turn did the ideas of Foucault help inspire new approaches to politics that challenged spatial yet geographically dead concepts of places and individuals simply holding power over powerless multitudes (Sharp, Routledge, Philo and Paddison, 2000). Power had to be rethought relationally in terms of the flows of ideas and interactions that created people (in different ways in different spaces) as both agents and subjects, a notable implication being that sites of subjectivity formation could thereby be reconceptualized as historical geographies of truth and power (e.g. Clayton, 2000). Applied to human–environment relations too and supplemented further by the work of feminist scholars (Haraway, 1991) and science studies (Latour, 1988), even the most concrete and stillled natural landscapes – such as the dammed waterscapes of formerly flowing rivers – could be rethought this way as flows of knowledge, power, capital and energy coming together in hybrid formations in different ways in different contexts (White, 1995; Swyngedouw, 1999, 2007).

In addition to these epistemological interests in the overdetermined landscapes of flow, worldwide events associated with recent rounds of capitalist globalization have also brought attention to the increasing flows of commodities, capital, information and people across borders. For example, the growth of cross-border flows of international trade (especially their increasing size as a proportion of world GDP) provides a key index of increasing global economic interdependency, an index that is only eclipsed in its significance by the even more rapid acceleration of cross-border investment flows (foreign direct investment) as a sign of the growing importance and independence of transnational corporations
FOCUS GROUP

vis-à-vis nation-states (Dicken, 2003). Other increasing and accelerating flows – transnational flows of information on the Internet, flows of news images and popular culture through cable and satellite TV, flows of migrants and tourists over barriers big and small, flows of illegal drugs and weapons, for instance – all comprise complex component parts of the ‘space of flows’ that has been famously associated with the rise of a globalized so-called network society (Castells, 1996b). But whereas Manuel Castells was careful to underline that ‘the space of flows is not placeless’ (Castells, 1996b, p. 416), other scholars have been prone to joining their empirical observations of globalized flows with extreme epistemological emphases on deterritorialization that tend to suggest an end to geography altogether. For example, in his otherwise astute arguments about the transnational networks of modernity (and especially of contemporary migration), anthropologist Arjun Appadurai (1996) ignores the ways in which global flows reterritorialize and create new landscapes in the same moment as they eclipse older ones (see Sparke, 2005).

By contrast, geographer John Agnew approaches the problem with a keen sensitivity to the ways in which flows create geographical integration and differentiation at the very same time. ‘The main novelty today,’ he says in a comprehensive rebuttal to end-of-geography arguments, ‘is the increasing role in economic prosperity and underdevelopment of fast-paced cross-border flows in relation to national states and to networks linking cities with one another and their hinterlands and the increased differentiation between localities and regions as a result of the spatial biases built into flow-networks’ (Agnew, 2006, p. 128).

focus group A qualitative method used to obtain opinions and experiences from between six and twelve people who participate in a group discussion organized around a series of topics or questions posed by the researcher/facilitator. Focus groups typically supplement other methodologies, and can be useful at different points in the research process: to get oriented to a new research field; to generate hypotheses that can then be tested more systematically; to gather qualitative data about experiences and opinions; and as a means of presenting preliminary interpretations to a community for validation. Focus groups are used instead of interviews or questionnaire surveys if the researcher believes that the group conversation will spark ideas among participants so as to elicit a richer understanding of the issue at hand. They provide an opportunity to observe how ideas develop in context, in relation to other and sometimes contradictory opinions. Although the researcher carefully facilitates the event, it can be a less hierarchical, more negotiated research event. Focus groups can also provide an important opportunity for participants to exchange information and support each other.

Focus groups must be carefully managed and are not always appropriate. Power hierarchies within the group will persist and can potentially silence non-dominant members. When this happens, less dominant individuals are effectively excluded from the research process. For this reason separate focus groups are often conducted for men and women, or are divided in terms of other social categories, such as race, especially if this is relevant to the topic under discussion. It should also be recognized that focus groups are public events in which individuals give public performances and may be reluctant to disclose private details. The focus group risks being exploitative if the artificiality of the situation and the legitimacy of the research context lulls individuals into revealing private details. This is especially problematic if the individuals in the group know each other or are likely to encounter each other after the event.

A focus group is not equivalent to interviews with between six and twelve individuals. A focus group is a singular conversational event. For this reason, at least five or six focus groups should be done in order to assess the thematic consistency across them. Similar to interviews, they are taped and transcribed. But they invite a different approach to analysis. Rather than focusing simply on the declarations of individuals, they provide an opportunity to study the generation of meaning, as opinions are debated, qualified and potentially modified. There also is a situational geography to focus groups that is under-explored. The rules of discourse, what and how one is told, vary with the context (Pratt, 2002). Geographers thus have the potential not simply to use this methodology, but to develop it in fascinating new directions.

food The study of the spatial and environmental aspects of food production, distribution and consumption. Food is a recurring
FOOD

concern in several academic disciplines because of its centrality to human life for both physical and social sustenance. As a specific sub-field with identifiable concepts and scholars, however, agro-food studies has come into fruition only recently, a reflection of both the resurgence of political economy, which found a new object of study in food systems, and the ‘cultural turn’ in social science that brought renewed interest in consumption. While scholars of food draw from anthropology – foodways has long been a staple of that discipline – and sociology, owing especially to the sociology of agriculture tradition, geography is in many respects at the cutting edge of food studies. Arguably, this is because geography is more ecumenical in its approaches, and because the spatial and environmental aspects of food are so critical to its theorizations. At the same time, there is a tendency to use food to illustrate other geographical topics, as demonstrated by the dozens of monographs published within the past 15 years that tell larger stories through particular food commodities.

Still, geographers have made considerable progress in producing and debating a set of meta-concepts relevant to the study of food qua food. They have contributed to different ways of theorizing the agro-food system, including systems of provision, commodity chains and food regimes. Recently, ‘food networks’ has become the favoured term in recognition of the fact that food distribution is more contingent than much of this earlier language implies, and that even long-distance trade depends on embedded social relations where trust must be secured (Arce and Marsden, 1994). Geographers have also looked at the scale dimensions of food provision and consumption (e.g. Bell and Valentine, 1997); and they have engaged in important debates regarding consumption, not only the politics of consumer purchasing in influencing the agro-food system (e.g. Cook and Crang, 1996), but also the bodily materiality of eating practices. In addition, geographers have played a leading role in developing some meso-level concepts, based largely on finely tuned empirical studies.

Famine, hunger and food insecurity persist as objects of study, especially as they pertain to uneven development and geopolitics. Watts (1983) was one of the first geographers to develop the concept of social vulnerability as it relates to the uneven effects of famine. Geographers have since adopted the language of food security, which not only encapsulates a more objective and positive characterization than ‘hunger’, but also highlights that food insecurity is rooted in insufficient income, entitlement or endowment (Dreze and Sen, 1989). These ideas underlie powerful critiques of how US food aid and concessionary sales of surplus commodities undercut livelihoods and thereby contribute to food insecurity. The activist-developed notion of community food security (CFS) suggests that the local community is the scale at which adequate and nutritious food should be ensured. CFS movements have noted the existence of food deserts, which are areas of poor access to the provision of healthy affordable food, usually related to lack of large retailers.

The twin themes of anxiety and trust are also pervasive in the geography of food, especially in light of the policy turn towards standards, labels and private regulation as the major response to recent ‘food scares’. While the broader goal of standardization is harmonization in the interest of trade – as exemplified in the Codex alimentarius – standards and auditing are increasingly employed to make commodity chains more transparent. Geographers have offered important criticisms of this new form of food regulation. Dunn (2003a), for example, has shown how attempts to impose harmony on an uneven geographical surface can have the effect of exacerbating differentiation among producers. Guthman (2004) has argued that organic food labels have perverse consequences for the intended goals of organic agriculture. Whether voluntary labels constitute a new sort of commodity fetish has been the source of a lively debate within geography.

The other major response to recent trouble in the food system is the creation of alternative food networks (AFNs). According to Whatmore, Stattser and Renting (2003, p. 389), ‘what they share in common is their constitution as/of food markets that redistribute value through the network against the logic of bulk commodity production; that reconvene “trust” between food producers and consumers; and that articulate new forms of political association and market governance’. AFNs have become a part of social movement strategies, and thus have been theorized as both alternative forms of development and resistance to globalization. For example, fair trade initiatives, which tie wealthy consumers’ moral concerns to the livelihood making of third world peasants, are what Goodman (2004) calls developmental consumption. Some scholars have been less
sanguine on these sorts of initiatives, which have considerable overlap with standard-based regulation. Mutersbaugh (2002) has noted that certification processes can create new work routines and new levels of surveillance.

Another area that has seen a good deal of recent empirical work is in the transformation and consolidation of food processing, marketing and retailing sectors. Many have commented on the enhanced power of retailers in food chains at the same time that supermarkets themselves have been at forefront of ethical trading initiatives (Marsden and Wrigley, 1995). Changing patterns of food consumption associated with the fast food industry and multiple-job households are becoming major objects of study, as well, articulating with public health concerns regarding a widely discussed crisis of obesity. This is an area that is likely to incite lively debate with geographers of the body, who are more sceptical of the discourse of obesity (Longhurst, 2005). This last research direction augments a growing literature attentive to the ways in which eating is simultaneously metabolic and ethical, such that the body is a site where various sorts of food anxieties are mediated (Stassart and Whatmore, 2003). Of course, virtually all of the above recent trends are interrelated and at the same time point to the extreme bifurcations within both food provision and consumption. For these reasons and many others, geography of food has become a rich area of enquiry indeed.

footloose industry An industry that can operate successfully in a wide variety of locations because it has no strong material orientation or market orientation requirements and wide spatial margins to profitability. Transport usually involves only a very small proportion of its cost structure – as in the establishment of call centres in countries many thousands of miles from the customers served.

Fordism The term used to describe both the manufacturing techniques and societal conditions underlying the mode of production developed by Henry Ford in the USA during the early 1900s. Ford revolutionized the production of the motor car, as well as manufacturing more generally, through his system which was based around four main principles: (1) vertical integration, whereby all elements of the manufacturing process take place at one site and assembly occurs on a moving production line; (2) scientific management and the principles of Taylorism that allow worker productivity to be increased; (3) standardization and economies of scale with a limited number or only one product model offered; and (4) mass consumption as a regime of accumulation, driven by the fact that workers are paid well and thus became consumers themselves and create a self-reproducing demand for goods.

As work framed under the regulation theory of political economy has shown, Fordism was widely adopted by manufacturers in the post-Second World War period and was applied to industries as diverse as biscuit production and film. Because of the unprecedented period of economic growth and stability associated with Fordism up until the 1970s, the period became known as the ‘Golden Age’ of Fordism (Glyn, Hughes, Lipietz and Singh, 1991). However, the very principles upon which Fordism was founded were also responsible for its undoing in the 1970s. Consumers began to develop a disdain for the homogenization associated with the one size fits all approach of Fordist manufacturing. Scientific management and the deskilling of work led to worker dissatisfaction and frustration, because of the monotonous and time-pressurized production in factories. In addition, economic instability, particularly associated with the OPEC oil crisis, led to a slow-down in wage increases, thus threatening the whole regime of accumulation upon which Fordism was founded. At the same time, workers began to rebel against the way management and workers were distinct and separate categories in Fordism. This created a little opportunity for progression, but most significantly meant that wage negotiations between labour and management took place through collective bargaining, something accepted in times of large wage increases but rejected as wage increases declined. However, as Sayer and Walker (1992) point out, this does not mean that Fordism ended in this period and was replaced by post-Fordism. Rather, Fordism was challenged (but not necessarily displaced) by the (re-)emergence of different logics of production and accumulation.

For geographers, Fordism is often associated with the emergence of important industrial regions such as the Black Country in the West Midlands of the UK (see Daniels, Bradshaw, Shaw and Sidaway, 2005); industries such as film production, in particular in
Los Angeles, that adopted Fordist principles at an early stage (see Christopherson and Storper, 1986); and also a gendered division of labour, in which the place of men was seen to be the factory and women the home (McDowell, 1991).

**Suggested reading**

**forecast** The construction of an estimated value for an observation unit, where the observation might be for a place, region, individual or time-period. The forecast may be generated by several quantitative models and methods (see prediction), and the term is usually employed for estimates applying to observations outside the group used in the model's calibration: it is an ‘out-of-sample’ estimate, most likely for a future time-period, or, in a ‘spatial forecast’, for a region not included in the estimation process (see space-time forecasting models).

**forestry** Most commonly, forestry refers to the development and application of knowledge and practices aimed at managing forests for human use. The word has a scientific connotation befitting the evolution of specialized, increasingly technical and professionalized knowledge about trees and forests aimed at their intentional manipulation, and of the particular emergence of silviculture as the science of growing trees. As a science, forestry emerged largely from German and French antecedents in the sixteenth and seventeenth centuries, from Japanese and Chinese precedents in the intentional growth and management of forests for wood, and from early-twentieth-century Scandinavian contributions, particularly in the areas of provenance, seed source and the intentional cultivation of seed stock for plantation forestry (Boyd and Prudham, 2003). This ostensibly technical field of knowledge, widely institutionalized under the auspices of forestry departments and programmes in universities and colleges, as well as in state agencies at various scales from local to national, and propagated via scientific journals, is part of what is conveyed by the term ‘forestry’. However, several questions arise in the very invocation of this specialized term, not least: What is a forest (and is it merely a collection of trees)? Which particular human uses dominate in shaping the trajectory of forest management? These ostensibly simple questions lead to the realization that forests and forestry, whatever else they are, comprise sites of struggle where interacting and contending processes of social and ecological reproduction are partially constituted. For instance, the management of forests emphasizing the reproduction of commercially valuable tree species, resolved primarily at the localized level of discrete stands of forests, has been the dominant practice of scientific forestry in the European tradition (epitomized by the German notion of Normalbaum). This approach was widely institutionalized in both Europe and North America between the mid-nineteenth and mid-twentieth centuries, and has increasingly been exported around the world. However, critical examination of this paradigm reveals that it is hardly ecologically or socially innocent, prescribing the elimination of older trees, for instance, as well as biological organisms whose existence depends on habitat compromised by conversion to plantations (e.g. the northern spotted owl in western North America), while at the same time privileging commercial timber interests over competing human values (e.g. hunting, fishing, trapping, gathering, recreation, agriculture etc.). All of this reinforces the need to avoid reifying apolitical renderings of forests that would naturalize them as non-human landscapes. Rather, as works such as E.P. Thompson’s Whigs and hunters (1975) demonstrates, it was not so long ago even in English history that forests were decidedly populated and contested, not least by conflicting property claims. Thus, as Willems-Braun (1997) more recently argued in the context of First Nation struggles in British Columbia, Canada, the apparently empty lands typical of scientific forestry representations are often sites of past and ongoing forced removals and exclusions. In short, despite its technical connotations and widespread professionalization, forestry is a complex categorical invocation of attempts to manage complex political ecologies, where trees, humans and other organisms interact, and where human attempts at intentional management rely on constructions of what is desirable and useful that can be (and are) politicized all the way down to the level of what constitutes a tree, and what does and ought to count as forest cover (Robbins, 2001).

**foundationalism** The assumption that knowledge claims must be grounded in a source of certainty that cannot be called into
question, and from which the truth value of other propositions can be inferred. Rationalist foundationalism identifies this ground of certainty in intellectual intuition of some sort; in other words, most of what we know we know by reasoning. Empiricist foundationalism identifies the grounds of certainty in sensory observation; in other words, most of what we know we know by experience (see EMPIRICISM). The key point about discussions of foundationalism is that they are concerned with epistemic justification – with establishing the grounds for justifying when a belief counts as knowledge (see EPistemology).

The most famous example of a foundationalist epistemology is Descartes’ cogito ergo sum (‘I think, therefore I am’), in which the act of thinking is identified as the foundational ground of certainty that can guarantee non-foundational beliefs. It is from the confidence of this I think (specifically, in response to the question ‘How do I know?’) that the possibility of justified knowledge claims is derived. Descartes established the criterion of certainty as the basis for epistemic justification. This leads to a radical scepticism about external reality. All foundationalist epistemologies share a monological, internalist view of the (human) subject of knowledge, confronting the external world wracked with doubt. Criticisms of foundationalism therefore have a content, in that they are about more than simply the best way of justifying belief; they are fundamentally about disputed pictures of what it is to be human.

Rorty’s (1979) repudiation of the idea that philosophy can ever possibly find the objective, transcendent grounds of certainty from which to justify belief informs a line of anti-foundationalist argument in human geography. For him, what confers epistemic justification on beliefs is whether they work, whether they are useful or whether they are held valid by a community of practice. This implies that the philosophical study of knowledge as an abstract conceptual matter of justification should at least be augmented by looking at how knowledge claims work in practical contexts (see PHILOSOPHY; Pragmatism). This type of empirical programme can certainly help us to understand the conditions that determine when claims will be believed as knowledge; but it closes down the question of when they ought to be so believed.

In geography, anti-foundationalist arguments are sometimes invoked to question the validity of explanatory social science, but it is far from clear that modern social science is vulnerable to the charge of foundationalism as this term is used in philosophical debates (cf. ESSENTIALISM). Geographers have also engaged in wider debates about the political significance of anti-foundationalist perspectives. These centre on the degree to which it is possible to square the academic disruption of knowledge claims, by showing them to be contingent and contextual, with the assumed requirement for political movements to be based on secure grounds of identity and experience. Various formulations finesse this problem, such as Judith Butler’s contingent foundations and Gayatri Spivak’s strategic essentialism. White (2000) develops the idea of weak ontology to negotiate the fact that any argument requires making presuppositions and fundamental ontological commitments, arguing that it is nonetheless possible to adopt a degree of rhetorical reflexivity to show their contingency (see ontology). But all of these formulas tend to rest on the ‘the implicit assumption that one could think like a sceptic but act like a foundationalist’ (Zerilli, 1998, p. 438), and therefore tend to misconstrue what is at stake in issues of foundationalism. The widespread assumption that anti-foundationalism involves a generalized affirmation of contingency betrays a scholastic perspective that is unable to grasp the conditions of its own critical doubt, and remains caught within the problematic of epistemic certainty. A less deceitful response to the problems of foundationalism might be derived from Wittgenstein’s considerations of scepticism. He held that absolute doubt of the sort entertained by Descartes does not provide plausible grounds for understanding the way in which knowledge works in practice: ‘the questions we raise and our doubts depend on the fact that some propositions are exempt from doubt, are as it were like hinges on which those turn’ (1969, p. 341). The point here is two-fold: the world of human affairs is not only held together by relationships of knowledge, either of certainty or contingency; and the expression of doubt is always undertaken in context, in relation to a particular set of concerns, and against a background of beliefs and commitments that stand fast. Fourth World The poorest and most vulnerable groups of people within the developing world (cf. Third World; see also South). Fourth World people are sometimes
Fractals are irregular objects that cannot be defined by traditional geometry but which, in some cases (such as Koch snowflakes) have the property of self-similarity: their pattern appears the same regardless of the scale at which they are viewed. The easiest way to explain fractals is by appeal to intuition. In cartography we are used to zero-, one- and two-dimensional objects representing point, line and area features on a map. Simply by looking, it is obvious that each higher-dimensional object fills more of the space than a lesser one: a rectangular object fills more of the map than a line placed along one side of the rectangle or a point positioned at one of its corners. There is a connection between dimensionality and space filling.

Now think of a number line. Although we often count using whole numbers (1, 2, 3, . . . ), we also accept that the line is continuous and so provides us with fractions (1, 1.2, 1.31, 1.411 etc.). Can the same principle be applied to dimensions?

Various nineteenth- and twentieth-century mathematicians have shown that it can. Of particular interest to geographers is Benoît Mandelbrot’s (1967) question, ‘How long is the coast of Britain?’ As he showed, there is no one answer: it depends on the precision of the measuring device – the calliper – used to trace around the islands (see measurement). As the precision increases, more of the detail of the coastline is included and the apparent length increases.

To imagine the problem another way, suppose that we could encode the coastline in perfect detail in a digital mapping package such as a geographic information system. Each time we ‘zoomed in’ to a fixed location on the coast more of its detail would be revealed. This would happen every time, without limit, because fractals possess infinite detail. Of course, we cannot really encode this infinite detail and so the total measured length of the coastline becomes dependent on the scale of analysis – by how the coast is generalized. Knowing this, we can take the measurement at multiple scales, to plot the (natural log) of the coastline length against the (natural log) of the calliper used to measure it. The gradient of the line of best fit to these values is an estimate of the coastline’s fractal dimension.

This may sound abstract, but fractals are evident in nature: leaves, trees, river networks and so forth. Their relevance is not just to the physical landscape. Within the social sciences, fractals can be used to model the processes of urban morphology (Batty and Longley, 1994). Reciprocally, the fractal dimension, as a measure of space filling, can be used to model sprawl or compactness of cities. Fractals can be linked to chaos theory: the idea that physical or social systems that appear to be chaotic can actually be modelled by clearly defined ‘laws’ or theories (e.g. using economic theories to model urban development and growth: see Batty, 2005). Finally, fractals are used in remote sensing to compress (reduce the file size) of images.

Free port An enclave within a country – typically a seaport, though increasingly other areas – where import and export (customs) duties are either not imposed or are reduced. This enables both warehousing and manufacturing functions to be located there producing a local comparative advantage and generating employment and wealth, at a cost advantage over other locations (cf. export processing zone). Free ports (such as Copenhagen, Danzig and Hamburg) existed in Europe until the mid-twentieth century, and free port status was a foundation of the economic success of Hong Kong and Singapore. The concept has been adapted for some airports – as at Shannon in the Irish Republic – and was reworked into that of the urban enterprise zone by the geographer Sir Peter Hall in the late 1980s to promote redevelopment in run-down industrial areas through tax advantages. Special Economic Zones (SEZs) with very similar characteristics are now widespread in the global south: India initiated a programme in 2000 and by
but many EU, and enhance North–South trade barriers, are within the global Trade Areas as detrimental. The two largest trade opponents see such ‘Preferential’ rules for proponents, FTAs catalyse global free trade; opponents see such ‘Preferential’ Trade Areas as detrimental. The two largest are within the global North, NAFTA and the EU, and enhance North–South trade barriers, but many South–South and North–South FTAs exist (the latter usually initiated from the North).

friction of distance The frictional or inhibiting effect of distance on the volume of interaction between places (including migration, tourist flows, the movement of goods and the spread of ideas and diseases: cf. diffusion): empirical regularities in interaction patterns consistent with the effect are characterized by distance decay. The effect is generated by the combined impact of the time and cost involved in overcoming distance, which varies according to the available transport and communications infrastructure. The frictions of distance are reduced with technological improvements in that infrastructure – though not necessarily to the same extent everywhere (cf. time-space compression; time-space convergence; time-space expansion).

friends-and-neighbours effect A form of contextual effect identified in electoral geography whereby voters favour local candidates (even if this means abandoning their traditional party preferences) because either they know the candidate personally or and they believe that her/his election will promote local interests. The concept was developed in Key’s (1949) analyses of intra-party voting in the US South and generalized by Cox (1969) and others. Candidates who are successful through this strategy may reward their constituents by winning public expenditure for the area (cf. neighbourhood effect; pork barrel).

frontier A frontier marks a limit. It has been used in two main ways. In the first case, it refers to the limits of a state. The frontier of a state is its border with another state. In modern times, this frontier is thought of as a line, since the sovereignty of a state is asserted as continuous up to its edges. In medieval Europe, however, feudal monarchs understood that their authority waned towards the periphery of their lands: these regions were termed ‘marches’ and the marcher lords had significant autonomy (see feudalism). The emergence of the modern atlas showing countries in different colours with distinct borders represents (and in part produces) a world very different from the early modern period and conformable with the presumptions of modern nation-states (Black, 1997).

Modern state frontiers are often contentious too, and a whole branch of geography developed on the pretension that borders could be settled scientifically (Curzon, 1888; Holdich, 1916). These scholars paid attention to the distribution of ethnic groups, and to the existence of regions that were difficult to settle or cross. An efficient border would clearly separate different sorts of people by a line that was in an isolated region, presenting a significant challenge to transgressors. In fact, these borders reflected the geopolitical interests of global superpowers (see geopolitics), and the first major international attempts at comprehensive border-setting served the colonial interests of European powers in Africa (at the Berlin Conference in 1884–5) and of the major global powers with regard to Eastern and Central Europe (at the Paris Peace Conference in 1919). The peoples of Africa and of Eastern and Central Europe were not consulted.

The second sense of frontier is as a line between settled and unsettled lands, cultivated and uncultivated. This is equally contentious. It almost always, in fact, separates one society from another and yet is presented as the separation of society from emptiness (cf. terra nullius). The most famous of these frontiers is that about which Frederick Jackson Turner developed his frontier thesis. The settlement of North America by Europeans expelled native peoples from their lands. The Europeans persuaded themselves that only sedentary cultivation was true civilization.
and that lands not used for that purpose were at best wasted, even empty. Viewed, rather, as an act of COLONIALISM or IMPERIALISM (Meinig, 1986), frontiers mark an important topic for comparative study.

Fawcett (1918); Lamar and Thompson (1981).

**frontier thesis** The argument developed by Frederick Jackson Turner (1861–1932) concerning 'The significance of the frontier in American history' (Turner, 1893). The US CENSUS had been mapping the limit of European settlement as a FRONTIER moving across the land from east to west (Paulin, 1932). In 1890, the Census announced that there was no longer a clear line separating the areas to the east settled at greater than two persons per square mile and those to the west that were more sparsely settled. Instead, there was now a patchwork of less densely settled areas in the west, and the idea of a continuous frontier between more and less densely settled parts was no longer valid. Turner took this to be the end of a distinct PROCESS. In 1892, speaking to historians gathered in Chicago on the occasion of the 400th anniversary of European entry to the Americas, Turner addressed the implications of the closing of the American frontier for democracy in the USA.

Turner claimed that, at the frontier, Europeans were forced to revert to more primitive forms of CIVILIZATION. In this way they broke their links with Europe and began to create a new and distinctly American society. At the frontier, society passed through all the stages from hunting up to the ultimate form of civilization, urban–industrial society. By passing through all these stages, Euro-Americans re-learned for themselves the need for DEMOCRACY, lessons that people in Europe took so much for granted as to have almost forgotten. Yet this learning was at the heart of the popular democracy that Turner cherished. With the closing of the frontier, a new way would have to be found to keep these lessons alive. Universities, he argued, would now have to act as the keepers of a truth that would no longer be learned naturally at the frontier.

These ideas have been much criticized, most notably by the so-called New Western Historians (Kearns, 1998). Limerick (1987) argues that Turner only credits Euro-American men with historical agency, and ignores issues of RACE, CLASS and GENDER. A historical process that consigns the native peoples of America to a shrinking margin makes it difficult for them to make claims about their right to a future in this land. Limerick also argues that rather than being legible as a process moving from east to west, European COLONIALISM in North America included significant movement of Spanish-Americans from the south, and of other Europeans who began not on the east coast, but on the west. The frontier that Turner speaks of is a farming frontier based on family farms, and yet large parts of the USA were taken from native peoples for large-scale ranching or mining without passing through the sort of family farms and villages that sustained Turner's nascent democracies. Finally, Turner actually misses many of the distinctive features about the American West, including the continuous role of the STATE in the ECONOMY.

Cronon (1987); Turner (1893).

**functionalism** A term found across the social sciences and used to explain variously mental, behavioural and social phenomena by the role that they play – which is to say, their function – in maintaining the larger SYSTEM of which they are part. The larger system comes first, reaching back to determine the functional roles of its various parts in enabling its reproduction and development.

As an explanatory strategy, functionalism was first systematically stated in nineteenth-century Darwinian evolutionary biology. Physiological characteristics were explained by their functional role in enabling the systemic ends of species survival and reproduction (see DARWINISM). Not surprisingly, when the French sociologist Émile Durkheim (1858–1917) introduced the same idea into sociology in the late nineteenth century, he drew on a biological analogy and likened the division of labour in society to the functional role of organs within a body. For Durkheim, the larger ends of stability and survival determined how society's constituent parts functioned. Durkheim's work influenced a group of British-based anthropologists – Bronislaw Malinowski (1884–1942), Alfred Radcliffe-Brown (1881–1952), Edward Evans Pritchard (1902–73) and Meyer Fortes (1906–83) – who developed STRUCTURAL FUNCTIONALISM. While on the surface the various cultures that they studied – the Trobrianders, the Nuer, the Tallensi – seemed quite different, they proposed that a common functional operation underpinned all of them: the components of culture worked together to promote smooth
equilibrium and effortless reproduction. Structural functionalism entered sociology through the work of American sociologist Talcott Parsons (1902–79) and was later developed as ‘systems theory’ by Parsons and by Niklas Luhmann (1927–99). Outside of the anthropology–sociology nexus, functionalism was also incorporated into some forms of Marxism, provoking new theorizing about the nature of functionalist explanation (Cohen, 1978; see also ANALYTICAL MARXISM), and in the philosophy of the mind, where mental states are conceived as a function of the cognitive system of which they are part.

Oddly, given the influence of Darwinism on geography and the magpie quality of geographical theorizing, functionalism was never prominent in the discipline. It weaved in and out of some early writings by European geographers, including Ratzel’s ANTHROPOGEOGRAPHY and Vidal de la Blache’s vision of HUMAN GEOGRAPHY. There were hints of functionalism in Hartshorne’s (1939) notion of the REGION as an ‘element complex’, and even stronger ones in the systems analysis introduced to the discipline in the 1970s (although it was mainly confined to environmental issues: see Bennett and Chorley, 1978). The most likely location for structural functionalism within the modern discipline was SOCIAL GEOGRAPHY, but by the time it became interested in theoretical formalization, the star of structural functionalism was fading in both anthropology and sociology. Functionalism was more significant in early RADICAL GEOGRAPHY. Thus Harvey (1999 [1982]) conceived space and place as functional elements in the reproduction of capitalism: capitalism reached back to ensure that its landscape regenerated the system. Even crises – the annihilation of space, the destruction of place – were functional. Similarly, the REGULATION SCHOOL advocated a posteriori functionalism in its analysis of capitalism (the success of the functional relation is known only after the fact of its success).

All this said, the functionalism found in human geography is often only implicit. Further, given the drubbing that functionalism has received over the past half-century – it is variously accused of determinism, of neglecting historical context, of denying individual agency, of imbuing collective entities with characteristics germane only to individuals and of neglecting causal mechanisms – it is unlikely ever to become explicit.

Giddens (1977, ch. 2).

**fuzzy sets/fuzzy logic** Sets (categories, classes, types) for which the definitions of class membership are vague or ‘fuzzy’, and contrast with the sharp, clearly defined definitions used by standard logic and set theory. Thus ‘deprived’ and ‘middle-class’ are fuzzy categories in everyday life and usage, only converted into precise categories by government or other statistical definitions. Fuzziness describes a type of UNCERTAINTY, but it is not the usual uncertainty of probability (e.g. the percentage chance of a US citizen being in the ‘deprived’ category). It describes ‘event ambiguity’, the degree to which an event occurs, not whether it occurs. Most quantitative and statistical modelling assumes non-fuzzy sets, and only a few studies have developed fuzzy-set applications relevant to geography, notably Openshaw’s work on SPATIAL INTERACTION using fuzzy distances (‘short’, ‘average’, ‘long’: Openshaw and Openshaw, 1997). Openshaw (1996) saw fuzzy logic as a key to make ‘soft human geography’ more scientific, but most would paint a much more modest picture of its potential.

Suggested reading
Openshaw and Openshaw (1997); Robinson (2003).
**game theory** A theory of interdependent decision-making. Individuals (‘players’) choose their actions (‘strategies’) with limited or zero knowledge of those of the other players, but with knowledge of the ‘payoffs’ (costs and benefits) of different joint outcomes. The theory was taken up by von Neumann and Morgenstern in *Theory of games and economic behaviour* (1944) and has been extensively developed and applied in economics and other social sciences, notably political science and sociology. In geography a pioneering study was that by Gould (1963), which showed how African farmers’ agricultural strategies could be modelled as ‘a game against nature’, with the farmers gaining different benefits depending on what they produced and what weather nature chose to throw at them.

Game theory tries to deduce the equilibrium strategies of players under rational decision-making. Games may be non-co-operative (where each player only considers their own benefits and costs) or allow co-operation between the players. A classic example where individual rational choice leads to collective sub-optimality is the prisoner’s dilemma. A geographical example of a simple competitive, two-person, zero-sum game is the model of two ice-cream sellers on a linear beach, with a uniformly distributed population of consumers. If consumers buy from the nearest seller, then the rational seller strategy is to locate back-to-back in the centre of the beach – any other location gives an advantage to the other seller (see Hotelling model). Yet, from the consumers’ angle, this is sub-optimal. They would benefit more if the sellers located one-third from the two ends of the beach, so that consumers had to walk less. (Of course, this assumes that both sellers have identical prices for identical products; see Hotelling model.) Much of the later theory has concerned how non-co-operative games can lead to non-zero-sum payoffs under various assumptions, and this work (starting with John Nash’s work in the early 1950s) lies behind much of the modern theory of economic markets and bargaining.

Game theory has been applied to problems of interregional externalities, where actions in one region are interdependent with those in another, as in water resource development, pollution strategies and environmental policy, and in economic policies within a federal state such as the USA or an economic union such as the European Union. It has also been extended to dynamic games, where learning takes place and sequences of choices are made and where there may be ‘leaders’ and ‘followers’ (the Stackelberg game), as in federal–local policies. However, most of these studies are by economists, and, as economic geography has increasingly lost contact with much of recent economics, few geographers have pursued these developments.

**garden city** A relatively spacious and small, self-contained planned settlement. Originally conceived by Ebenezer Howard (1850–1928), the concept was adopted by the British Garden City Movement, which he founded. It formed the basis for two settlements – Letchworth (1903) and Welwyn (1920) – in Hertfordshire: both are now much larger than Howard originally envisaged (c. 32,000 people on a 6,000 acre [~2,430 ha] site). The idea of low-density, relatively small, high-quality settlements characterized by their ‘greenness’ was adopted in a number of countries during the twentieth century, as part of a planning ideology based on community (cf. neighbourhood unit): indeed, the garden city movement was the precursor in the UK of the Town and Country Planning Association, which remains a powerful pressure group. The general concept was transferred to other countries and influenced the planning of numerous new settlements – such as Canberra – and new town movements, as in the USA.

**gated communities** While associated with the large US urban regions (Blakely and Snyder, 1997), gated communities are increasingly global in their distribution (Webster, Glasze and Frantz, 2002). They are residential enclaves demarcated physically by walls, fences and secured gateways, which are often
patrolled by private security guards. They are also frequently governed by community associations that regulate residents’ activities and design decisions. The proliferation of gated enclaves, private GOVERNANCE and SECURITY is generally understood to lead to the delegitimization of PUBLIC SERVICES and is a physical manifestation of growing resistance to ‘democratization, social equalization, and [the] expansion of citizenship rights’ (Caldeira, 2000, p. 4; but see Salcedo and Torres, 2004). Thus, gated communities have been the focus of research not only because of their global presence but also because of what they suggest about perceptions of security, COMMUNITY, CITIZENSHIP, PUBLIC SPACE, PROPERTY and the role of the STATE in contemporary urban societies (cf. SURVEILLANCE).

GENDER
A categorical distinction between men and women; a technology of CLASSIFICATION that naturalizes sexual difference and is intertwined with other distinctions, such as nature/culture, and racial and national differentiation. PLACES become coded as masculine or feminine, and this can be one important means of naturalizing gender difference (Bondi and Davidson, 2003). Haraway (1991b) provides a thorough discussion of the history and meaning of the term ‘gender’ within feminist theory through to the mid-1980s (see FEMINISM). The term has a broadly similar history within GEOGRAPHY: there has been a move away from theories of relatively static gender roles to gender relations, and towards a fuller exploration of how diverse gender relations are constructed in all spheres of life. Emphasis has been placed on the variety of femininities and masculinities – ways of living gender, depending on context and intersections with RACE, CLASS, RELIGION, SEXUALITY, nationality and other social and geographical DIFFERENCES (Bondi and Davidson, 2005; see also FEMINIST GEOGRAPHIES).

Within Anglophone feminism, ‘gender’ is typically contrasted to ‘sex’: the former is understood as a SOCIAL CONSTRUCTION, the latter defined by biology. The distinction has been part of an effort to denaturalize conventional understandings of women and femininity, to remove women from NATURE and place them within CULTURE as constructed and self-constituting social subjects (see PHALLOCENTRICISM). The treatment of gender within GEOGRAPHY is slightly unusual in this regard, as it has not been ‘quarantined from the infections of biological sex’ (Haraway, 1991b, p. 134) to the same extent as in other disciplines. In an effort to theorize PATRIARCHY, for instance, Foord and Gregson (1986) identified necessary relations that constitute gender relations. Following the analytical procedures of REALISM, they reasoned that two genders, male and female, are the basic characteristics of gender relations. In order to theorize the necessary relations between these basic characteristics, they ask ‘Under what conditions do men and women require each other’s existence?’, to which they answer, for biological reproduction and the practice of heterosexuality. Foord and Gregson’s analysis was quickly criticized, because it made it difficult to theorize how CAPITALISM structures gender relations (McDowell, 1986) and for its biologicalism, especially in terms of its portrayal of heterosexuality as biologically or psychologically fixed (Knopp and Lauria, 1987).

The latter criticism signalled important new ways of thinking about the relations between sex and gender. The feminist distinction between sex and gender may save gender from ESSENTIALIST or naturalizing versions of femininity, but it repeats the problems of the nature/culture dualism insofar as it posits gender as the (active) social that acts upon the (passive) surface of sex. It is itself thus vulnerable to the charge of MASCULINISM: ‘Is sex to gender as feminine to masculine [as nature to culture]?’ (Butler, 1993a, p. 4). A further problem is that within the terms of the sex/gender dualism sex seems to disappear once it is gendered: gender absorbs and displaces sex (these tendencies within geography are discussed by Nast, 1998).

Drawing upon theories of DISCOURSE, DECONSTRUCTION and PSYCHOANALYSIS, Butler (1993a) tackled this problem by arguing that both sex and gender are socially constructed. Neither sex nor gender has ONTOLOGICAL STATUS and neither can be theorized apart from regimes of (hetero)sexuality. For Butler, sex is neither extra- nor pre-discursive: the sexed BODY is brought into being through the regulatory regime of heterosexuality. Within HETERO-NORMATIVITY, we must be gendered and sexed as either male or female to be human: she argues that those who are not properly sexed are threatened by psychosis (unstable bodily and psychic boundaries) and ABJECTION. Gender is a truth effect of a discourse of a primary and stable identity: this identity emerges out of repetitive gender performances, which are instantiations of an ideal/
norm (see PERFORMATIVITY; SUBJECTIVITY). Butler does see opportunities to prise performances of sex and gender apart: the subversive potential of drag performances, for example, lies in the disjunction between (an assumed interiorized) sex and exteriorized gender performances, as well as the performance of the sexually disallowed or unperformable (e.g. men acting out conventions of femininity). The implications of this retheorization of gender and sex are far reaching: gender is recast as derivative of the regulatory norms of (hetero) sex and as repetitive and unstable practices enacted in different ways in different places and times. This invites close attention to the persistent deployment of regulatory regimes of heterosexuality, to the sexualities that operate derivative of the regulatory norms of (hetero) sex and as repetitive and unstable practices enacted in different ways in different places and times. This invites close attention to the persistent deployment of regulatory regimes of heterosexuality, to the sexualities that operate at the margins of and exceed the boundaries of these norms, and to the geographies of both (see HOMOPHOBIA AND HETEROSEXISM; QUEER THEORY; SEXUALITY; Nash, 1998; Hubbard, 2000).

The material limits to social constructivism and a focus on life that exceeds DISCOURSE has drawn increasing attention. Another approach to the problem that the sex/gender dualism replays a phallocentric binary (one that complements rather than contradicts that of Butler) has been to emphasize the agency and dynamism of nature. Grosz (2005) articulates this strategy when she implores feminists to attend to ‘matter’ as ‘that which preconditions and destabilizes gender and bodies, that which problematizes all identity’ (p. 172). Echoing Butler, she understands gender to be a contained, represented, socialized, phallocentric ideal and, following Irigarary, she directs feminist enquiry away from gender to sexual difference, which she associates with an unbounding and proliferation of identifications, ontologies and ways of knowing.

Ramon-Garcia, Simonsen and Vaiou (2006) note that the debates about the sex/gender binary are specific to particular LANGUAGE communities: feminists theorizing within languages for which there is no distinction between sex and gender have developed non-essentialist arguments about gender without drawing on this dualism. Even within Anglophone feminism, there have been other approaches to theorizing the category of woman outside of the gender/sex binary. Bondi and Davidson (2003) call upon Wittgenstein’s notion of ‘family resemblance’ to theorize the category ‘woman’ as a loose network of similarities rather than essential qualities, and Iris Marion Young (1997b) has theorized the gender of woman as a series brought together by context-specific material conditions rather than as a set of embodied characteristics or an identification.

Bondi and Davidson (2003).

**gender and development** A contested landscape of theoretical and political approaches to gender, or the woman question in DEVELOPMENT, where Women in Development (WID), Women and Development (WAD) and Gender and Development (GAD) emerged as major discursive fields, broadly paralleling liberal, radical and Marxist/socialist feminist perspectives (Saunders, 2002). Of these, WID (whose beginnings can be traced to the works of Esther Boserup) has been instrumental in defining the hegemonic field of feminist development practices. Although it has enjoyed legitimacy and integration with major bi-/multilateral development agencies and the United Nations, WID has been critiqued within feminist and alternative development circles for its assumptions about sisterhood and its erasure of differences based on class, nationality and colonial histories and geographies.

For WAD theorists, inclusion and exclusion is related to hierarchical spatialization of the global CAPITALIST ECONOMY that shapes the differentiated spaces of core, semi-periphery and periphery; urban and rural; capitalist and subsistence sectors (see UNEVEN DEVELOPMENT). Since peripheral spaces are central to development’s local, regional and global formations, the THIRD WORLD’s poorest women are seen as an integral piece of exploitative capitalist development processes. For many theorists and collectives from the SOUTH, this understanding translates into a close correspondence between ‘experience’ and ‘visions’ in their theoretical centring of those poor Third World women whose bodies have become the objects of developmentalist interventions.

The GAD theorists centre on GENDER and CLASS relations rather than on women per se. They emphasize broader interlocking relationships between the rules, resources, practices and POWER through which social inequalities (gender, CASTE, class etc.) are constituted and played out in specific contexts (Kabeer and Subrahmanian, 1999). Like WID, GAD is also gynocentric. Unlike WID however, GAD’s socialistic orientation is reflected in a belief in the STATE’s redistributive and welfare role (see SOCIALISM). At the level of practice, the strategy of gender mainstreaming – particularly NGO-linked women’s
EMPOWERMENT – has become increasingly identified with GAD.

Since the 1980s, writings by post-colonial and Third World feminists have sparked sustained reflection and debate on the political and intellectual representations of the Third World woman in Western feminist discursive practices, and underscored that ‘woman’ is not a ‘real’ but a political SUBJECT, shaped through DISCOURSES and institutional actors with high political stakes (see POST-STRUCTURALISM; POST-COLONIALISM). For geographers, engagements with post-structuralist insights also translated into examination of how struggles over labour and resources reveal deeper contestations over gendered (and other) meanings in the ways that RIGHTS TO RESOURCES are negotiated and redefined within the political arenas of HOUSEHOLD, workplace and state (Carney, 1996). Katz (2004, p. 227) further spatializes processes of development and resistance through the notion of TIME-SPACE EXPANSION, which allows a simultaneous theorizing of: (a) the expanded field within which gendered and generational subjects engage in material social practices of production and reproduction; (b) the growing distance of the Third World’s villages from global centres, whose own interactions have been intensified through TIME-SPACE COMPRESSION; and (c) an acute awareness among people living in impoverished rural places, not only of being marooned in a reconfigured global SPACE, but also of what is to be had and the pain of absences created by this expansion of desire. (See also FEMINIST GEOGRAPHIES.)

genealogy A mode of historical enquiry that seeks to trace the emergence and descent of terms and categories, and the interrelation of power and knowledge in their deployment. The term is used in German philosopher Friedrich Nietzsche’s 1882 work On the genealogy of morality (1994; see Ansell-Pearson, 1994), although it is in a key essay by the French thinker Michel Foucault (1977c [1963]) and his subsequent adoption of the term to describe his own work that it took on its modern importance.

Foucault is concerned with showing how taken-for-granted phenomena actually have complicated and often-forgotten histories. In works on DISCIPLINARY POWER (1976a [1975]), sexuality (1978 [1976]) and political rationalities (see GOVERNMENTALITY), Foucault sought to undermine – in the sense of excavate and challenge – standard accounts and interpretations. He suggested that genealogy did not confuse itself with a quest for origins, but rather looked to the moment of emergence of a problematic and to trace its descent through all the circuitous paths it may have taken. Words have not remained with the same meanings, and so etymology may reveal much about a subject – an approach favoured by Nietzsche, and his fellow German philosopher Martin Heidegger – nor have established logics always been seen the same way.

Foucault claimed that his purpose in writing was not to write a history of the past, but a history of the present, in order to illuminate how we have arrived where we are, which will open up future possibilities of change and resistance. Foucault’s earlier writings had been described as archaeologies, and although the two approaches are sometimes seen as opposites, it makes more sense to see them as complementary, as Foucault often intimated. In Foucault’s usage, archaeology tended to look at the logics that conditioned the formations of knowledge in a given epoch (see EPISTEME), while genealogy introduced a complementary analysis of POWER, of the practices that follow from, and enable, knowledge.

Critics have charged Foucault’s approach as too negative, with Nigel Thrift (2000b, p. 269) claiming that ‘in Foucault country it always seems to be raining’. However, Foucault’s analysis of power sought to decentre it from concentration in the hands of a monarch, a STATE or a dominant CLASS, and to show how power flowed throughout SOCIETY, was not simply repressive and worked in complex interrelations – what he called ‘games of power’. In his terms, ‘where there is power, there is the possibility of resistance’, which his genealogical works sought to exploit. It was in this period that Foucault himself became much more politically active in campaigns around PRISONS, SEXUALITY and in journalism on the Iranian revolution.

Foucault refused any kind of TELEOLOGY in history, suggesting that there was no preordained logic to the course of events. Things could have been otherwise, and could be otherwise in the future. Geographers have made use of these ideas to take into account the spatial and well as temporal aspects (see, e.g., Driver, 1993; Philo, 2004), to which Foucault himself was generally attentive (see Elden, 2001). A whole range of historical analyses have been undertaken that are inspired by Foucault’s genealogical work, which are informed by a political and critical sensibility, an attentiveness to small details and textual analysis, and to deployments of power and constructions of IDENTITY and SUBJECTIVITY.

general linear model (GLM) A family of statistical procedures, used in the analysis of two or more variables, based on the covariation among those variables – the degree to which the pattern for one variable across a set of observations is replicated in another. Techniques based on this model are at the core of much spatial analysis, as well as in the analytical procedures of comparable disciplines (cf. spatial econometrics), and operational algorithms are available in most computer statistical software packages (cf. software for quantitative analysis).

The core of GLM is the technique of regression, which identifies relationships among variables, one or more specified as the independents (or causes, where causality is implied in the modelling) and another as the dependent (or effect): the associated correlation coefficient evaluates the regression’s goodness-of-fit. Other commonly used techniques include factor analysis and principal components analysis, which seek underlying common patterns in the correlations among groups of variables.

Data deployed in GLM techniques can be at any one of the four different levels of measurement – nominal, ordinal, interval and ratio – and variables of each type can be used in techniques incorporated within GLM, each having particular technical issues that may need resolution for it to be validly deployed. (Some ratio variables have pre-defined upper and lower values – such as percentages and proportions – and have to be transformed in order to meet the GLM requirements, as in categorical data analysis, logit regression models and poisson regression models: see also collinearity.) Spatial data raise the particular problems of spatial auto-correlation.

Apart from regression using interval and/or ratio data for both the independent and dependent variables, commonly used GLM techniques include the following:

- Analysis of variance (ANOVA), in which the dependent variable is either interval or ratio and the independent variables are nominal or ordinal (although nominal variables can be incorporated within a regression framework using dummy variables and continuous – interval and ratio – variables can be placed in ANOVAs using covariates).
- Binomial and multinomial regression, in which the dependent variables are nominal or ordinal (in binomial regression, there are only two possible outcomes; in multinomial there are more than two) and the independents are also nominal/ordinal – although continuous variables can also be incorporated as independent variables.
- Multi-level modelling, a form of regression (with either continuous or nominal/ordinal variables), in which the observations are clustered into nominal categories.
- Factor and principal components analysis.
- Discriminant analysis, in which the dependent variable is either nominal or ordinal and the independent variables are factors/components comprising groups of related continuous variables (with the groupings derived empirically rather than predetermined).

Many techniques in spatial analysis (such as geographical weighted regression: see also local statistics) are based on the GLM.

general systems theory (GST) An attempted development of universal statements about the common properties of superficially different systems, initiated by Ludwig von Bertalanffy (1901–72: see von Bertalanffy, 1968). GST was introduced to geographers during its quantitative revolution as a framework that could unite various strands of work, and used by some to promote links between human geography and physical geography (Haggett, 1965; Coffey, 1981): Chisholm (1967) dismissed it as an ‘irrelevant distraction’. The search for isomorphisms across systems focused on three ‘principles’:

- allometry – the growth rate of a subsystem is proportional to that of the system as a whole;
- hierarchical structuring (as in central place theory); and
- entropy.

Few substantial achievements resulted, however, apart from the early work on macrogeography and more recent analysis of fractals.

genetic algorithm A search technique deployed in computers to identify solutions to large optimization and other problems.
Initially, a large number of possible solutions is identified using random generating processes, and by iterative processes built in to the search algorithm alternatives are generated and assessed according to a fitness function until a solution is found that meets predetermined criteria (cf. Cellular Automata; Neural Networks).

**Genetic Geographies** An umbrella term for the ways in which geographers, among others, have been developing critical analyses in novel theoretical and methodological directions to address some of the profound social challenges to ideas of bodily integrity and intervention (see body); social identity and kinship; and the distinctiveness of living, in contrast to other material kinds generated by the practices and technologies of the life sciences (see also Human Genome). Geographers have been slower than some (notably anthropologists) to rise to the new questions and analytical opportunities presented by the biotechnological capabilities, processes and products that rely on various forms of genetic engineering, data banking and commercialization (Haraway, 1997). As well as contributing to the analysis of the space–times of bio-informatic scientific practices themselves (see Hall, 2003), geographers have been involved in studying the political economy of global struggles over corporate attempts to commercialize biodiversity (Hayden, 2003), the history of the genetic framing of ideas and practices of social ‘improvement’ (Flitner, 2003) and various interrogations of the bio-informatic management and manipulation of human genetic materials (see Greenhough and Roe, 2006). In this, genetic geographies can be thought of as a subset of the renewed interest in, and framing of, the project of biogeography that is distinguished by the ways in which it refocuses that project from the malleability of the world of nature ‘out there’ to the human being ‘in here’. SW

**Genocide** The deliberate systematic mass killing and physical liquidation (‘extermination’) of a group of human beings who are identified by their murderers as sharing national origin, ethnicity, race, gender or other social distinction.

The term was proposed by the Polish jurist Raphael Lemkin in his *Axis rule in occupied Europe* (1944), from the Latin genus (birth, class, order, tribe) and cida (a person who kills). Lemkin defined genocide as ‘the destruction of a nation or of an ethnic group’ and, as the title of his book suggests, he was concerned with the mass murders carried out by the Third Reich in occupied Europe, and specifically with what came to be known as the Holocaust (see also Fascism). Lemkin proposed that the industrialized murders of millions of Jews, Romanies, Slavs, gays and others should be deemed crimes against humanity, which he suggested involved either ‘barbarism’ – acts directed at the physical elimination of a group – or ‘vandalism’ – acts directed at the destruction of the group’s culture. But these distinctions have turned out to be problematic: partly because the first almost always involves a series of cultural constructions that sustain a narrative of purification and contamination to animate and legitimate the atrocities, so that it is difficult to hold the two apart, and partly because ‘barbarism’ and ‘vandalism’ are themselves historically sedimented.

**Genius Loci** The spirit of place, or the distinctive atmosphere found in a place. In Roman mythology, each place was protected by a guardian deity (a ‘genius’), embodied in the form of an animal or supernatural being. While resonances of this idea remain (e.g. in New Age notions of sites of mystical energy, such as Stonehenge), genius loci now primarily refers to the unique assemblage of cultural and physical characteristics that make a place distinctive, with a characteristic ambience. Loukaki (1997, p. 308) describes genius loci as ‘a place’s fingerprint’. Often found in literary depictions (the novelist Lawrence Durrell’s works are perhaps the most well known, especially his *Alexandria quartet*), genius loci has enjoyed only sporadic use in Human Geography, because it is such an imprecise, difficult to use and contested term. Early on, it was taken up by Herbertson (1915, p. 153), who viewed genius loci as the equivalent to the historian’s Zeitgeist or ‘spirit of the age’ (‘There is . . . a spirit of place, as well as of time’). During the 1970s, kindred versions of genius loci, although rarely the exact term itself, were championed in Humanistic Geography under the guise of ‘sense of place’, ‘topophilia’ and ‘personality of place’. More recently, the term has been taken up critically by Loukaki (1997), who has been concerned with its implications for ideology, and by Barnes (2004b), who links the term to recent work in Science Studies.
racialized terms that are impregnated with a EUROCENTRISM that identifies EUROPE with a privileged sense of CIVILIZATION.

In fact, genocide has a troubling relationship to Europe’s history and to the modern world more generally. Some commentators have seen the Holocaust as at once starkly modern and a hideous deformation of the project of MODERNITY, but others have insisted on its intimate connections with European modernity (Bauman, 2000b). Taking into account other genocidal regimes, Rummel (1994) estimated that during the twentieth century six times more people – 169 million – were killed by their own governments in what he called democide or ‘murder by government’ than were killed in war, and Levene (2000) has explored the logics of STATE and intra-state VIOLENCE in other directions to try to account for the twentieth century as ‘the century of genocide’.

Although the term ‘genocide’ is modern, however, and a host of other -cides – politicide, terricide or ‘the erasure of space’ (Tyner, 2008) and urbicide among them – have been proposed to identify other supposedly modern horrors, like its hideous kin ETHNIC CLEANSING, the practice of genocide has a much longer history. Many scholars have extended the term backwards in time (see, most comprehensively, Kiernan, 2007) and drawn attention to the role of genocide in the BIOPOLITICS of COLONIALISM and IMPERIALISM. Thus Wolfe (2006) describes a ‘logic of elimination’ that includes ‘the summary liquidation of indigenous people’ and the calculated destruction of their ways of life by settler colonialisms, and Davis (2001) identifies a global series of ‘Late Victorian Holocausts’.

The attribution of the term, past or present, is always highly charged because it combines juridical, political and analytical inflections (see Jones, 2006, pp. 15–22). Its origins lie in international LAW: following Lemkin’s campaign, the United Nations adopted the Convention on the Prevention and Punishment of the Crime of Genocide in 1948, but it was almost fifty years before prosecutions for genocide were brought before International Criminal Tribunals for the Former Yugoslavia (for crimes since 1991) and Ruanda (for crimes in 1994). The long interval can be explained partly by the protracted process of ratification, but partly by the implications of the term itself: ‘It aims to sound the alarm and oblige action’ (Stein, 2005, p. 190). In fact, Stein argues that the initial reluctance to designate clusters of mass killings as genocide has since yielded to the application of the term to so-called ‘new wars’ (see WAR) and other contemporary conflicts ‘in which large-scale cleanings, killings and brutalities occur . . . Whereas previously the problem was one of apparent singularity, currently it is that of near universality.’ This is something of an overstatement, as the controversy over the crisis in Darfur revealed (Straus, 2005; de Waal, 2005; Totten and Markusen, 2006), but it is clear that the attempt to ring-fence the Holocaust – as both paradigmatic and singular, what Wolfe (2006, p. 402) calls ‘the non-paradigmatic PARADIGM that, being the indispensable example, can never merely exemplify’ – has given way to a determination to analyse the logics and practices of extermination and atrocity, and to understand how ‘ordinary people’ could have taken part in state and para-state programmes of mass murder.

HUMAN RIGHTS organizations are vocal in their investigations (see, for example, http://www.genocidewatch.org) and there is now an international network of genocide scholars (see http://www.inogs.com). Geographical analysis has included the use of satellite photography and remote sensing techniques to identify mass graves (cf. Parks, 2001); studies of the destruction of PLACE and LANDSCAPE to eradicate any trace or even MEMORY of the targeted group’s presence; and comparative studies of contemporary genocides (Wood, 2001).

genre de vie A French expression meaning ‘mode of life’, used by Paul Vidal de la Blache, doyen of French REGIONAL GEOGRAPHY at the turn of the twentieth century, to describe the range of possible livelihoods developed by geographically bounded, socially distinctive, mainly rural COMMUNITIES. It was used alongside the related concepts of milieu (the geographical environment that provides a community with its resources) and circulation (the communications linking different communities) to make sense of traditional PEASANT societies that seemed destined to be replaced by modern, deracinated urban–industrial societies in both the developed and the developing worlds.

gentrification Middle-class settlement in renovated or redeveloped properties in older, inner-city districts formerly occupied by a
lower-income population. The process was first named by Ruth Glass, as she observed the arrival of the ‘gentry’ and the accompanying social transition of several districts in central London in the early 1960s. A decade later, broader recognition of gentrification followed in large cities such as London, San Francisco, New York, Boston, Toronto and Sydney undergoing occupational transition from an industrial to a POST-INDUSTRIAL economy. But more recently gentrification has been identified more widely, in smaller urban centres, in Southern and Eastern Europe and also in some major centres in Asia and Latin America (Atkinson and Bridge, 2005).

Explanation of gentrification has moved in several directions. One account focused upon HOUSING MARKET dynamics, in particular the POWER of CAPITAL to shape LANDSCAPE change (Smith, N., 1996b). Another emphasized the rapid growth of a ‘new class’ of private- and public-sector professionals and managers in post-industrial societies, who were drawn to urbane inner-city locations (Ley, 1996). Related to this occupational change was the movement of women into the new class workforce, and the growth of smaller adult-oriented–households well suited to central neighbourhoods. By the mid-1980s, the successful re-colonization in the older INNER CITY by the middle class was well established, and more recent developments have been the extension and intensification of gentrification in new forms, including loft conversions, the massive development of obsolete industrial land, frequently on waterfront sites, such as the London Docklands, and also the deepening of wealth in formerly gentrified areas, a process named ‘super-gentrification’ by Lees (2003) from studies in New York and London.

The sustained interest in gentrification research for more than a generation has resulted in part from its engagement with a number of important conceptual categories including CLASS, GENDER, and, most recently, RACE, patterns and styles of CONSUMPTION, housing and other service needs, social polarization and the GOVERNANCE practices of NEO-LIBERALISM in the GLOBAL CITY. In addition, it has been a forum where competing EPISTEMOLOGICAL and theoretical positions have met (Hamnett, 2003).

Gentrification has been seen ambivalently. Positive impacts include new investment in areas often requiring significant land use and service improvement, the enhancement of the urban tax base, and the creation of new (though typically low-income) service jobs in such fields as the restaurant and arts sectors, home renovation, cleaning and security. But against this has been the massive loss of affordable inner-city housing for lower-income groups, an integral element of the polarization of life-chances in the global city. Gentrification has become a conscious policy strategy in many cities seeking to reconfigure their urban economies and landscapes in the wake of massive DEINDUSTRIALIZATION. Regeneration policies, from Amsterdam to Vancouver, frequently seek a putative ‘social mix’ that includes middle-class housing in former working-class neighbourhoods. Not surprisingly, gentrification has frequently become a politicized and contested process of residential transformation.

Atkinson (2003); Atkinson and Bridge (2005).

geo-body The spatial expression of the modern NATION. It is the socially constructed ‘territorial definition which creates effects – by classifying, communicating, and enforcement – on people, things, and relationships’ (see TERRITORY). This definition is derived from the work of cultural historian Thongchai Winichakul, who coined the term in his study of the cultural construction of the Siamese/Thai nation, in which he argued that the nation’s spatial extent is not unproblematic but, rather, is a naturalized and mythic construction, a component of the ‘life of the nation’ that is at once ‘a source of pride, loyalty, love, passion, bias, hatred, reason, [and] unreason’ (Winichakul, 1994, p. 17). It is important to distinguish between state mapping and the construction of the ‘geo-body’. State mapping, the CARTOGRAPHY of the modern STATE, entails detailed medium- and large-scale topographical mapping which, along with thematic–statistical mapping, allows the STATE APPARATUS oversight over its territory and population (see GOVERNMENTALITY). The cartographic imaginary of the modern nation, by contrast, entails the deployment of simple and simplistic small-scale maps within emotional and nationally emotive discourses, especially those carried on through news media and primary school texts (cf. EMOTIONAL GEOGRAPHIES). It is this second cartographic practice that finds resonance in subsequent studies of the cartographic construction of national IDENTITY, whether post-colonial (e.g. Ramaswamy, 1999) or European (e.g. Herb, 1997). Indeed, Winichakul’s work prompted Anderson (1991a [1983]) to extend his crucial conception of nations as ‘imagined communities’ to encompass...
the self-conscious formation of national identities through maps, and in particular through ‘logo maps’ that sketch in outline a simple and homogenous space imbued with nationalistic sentiments: more generally, Helgerson (1992) convincingly argued that a modern nation requires a spatial self-conception and that such self-conceptions are constructed cartographically. From these studies, it seems appropriate to limit the use of ‘geo-body’ to the spatial embodiment of the nation and its self-imaginings, leaving each state to construct and define its territorial and political limits through markedly different cartographic practices, technologies and discourses.

**geocoding** Geocoding is the act of converting paper maps into computer-readable form by scanning or digitizing (Clarke, 2002, p. 313) or, alternatively, the act of assigning a location to information (Longley, Goodchild, Maguire and Rhind, 2005, p. 110). Despite revealing that there is no standardized nomenclature for geographic information systems (GIS), these two meanings cover common ground. To convert or to encode geographical information digitally in a GIS requires that both the characteristics and the locations of the features of interest be stored in a database, usually in vector or raster format. Recording what is found and where gives GIS its mapping and spatial analytical capabilities.

**geocomputation** The technique of geocomputation applies the processing power of computers to enable advanced geographical analysis and modelling. However, this broad definition conceals a diversity of methods and philosophies, leading Couclelis (1998, p. 18) to ask ‘whether geocomputation is to be understood as a new perspective or paradigm in geography … or as a grab-bag of useful computer-based tools’. To some, the spirit of geocomputation is conveyed by Openshaw, Charlton, Wymer and Craft’s (1987) *Geographical Analysis Machine* (GAM), designed to look for spatial clusters within child leukaemia data for northern England. As a method of spatial analysis and local pattern detection, it is characterized by iterative repeat testing, subdividing the study region into overlapping regions, within each of which a significance test of the rate of incidence (of leukaemia) is undertaken. Such a technique is often portrayed as inductive (cf. induction): drawing out ideas, inferences and working hypotheses from what is found in the data, and suggesting that the process of geographical knowledge construction is data-driven or ‘avowedly empirical’ (Longley, Brooks, McDonnell and Macmillan, 1998). However, that portrayal is not entirely satisfactory given any *a priori* postulate or theorization that radiation causes leukaemia and therefore an expectation that a cluster of cases be found in proximity to a nuclear power station. Finding the cluster does not prove the theory, but it may add circumstantial evidence. In this manner, geocomputational practices are abductive (cf. abduction): interesting cases (or spatial ‘hot spots’) are used to support a plausible although not logically necessary conclusion, not a purely (inductive) empirical generalization. Others pursue a more deductive tradition of scientific practice (cf. deduction), with the foundations of geocomputation established firmly in the analytical traditions of spatial science and geography’s quantitative revolution (see, for example, the history of geocomputation outlined at www.geocomputation.org). Here, the focus is on modelling, analysing and theorizing dynamic socio-economic or physical systems (cf. model); on modelling spatial distributions, flows, networks, hierarchies and diffusions. In particular, there is an interest in methods of simulation – from a human geography perspective, of simulating the spatial patterning, causes and consequences of population change, urban morphology, economic cycles, transport congestion and so forth. These methods build on the idea of Monte Carlo simulation outlined by Haggett (1965). It means that the rules of the system (assumed from, say, economic theory) are played out in virtual spaces, where what came before affects what follows, but the geographical outcomes are not entirely fixed or predetermined. Instead, there is randomness in the system – the ability to generate particular chance events – albeit that the consequences of those events are often constrained by the context in which they are generated; for example, their locations and the ‘state’ of the system around them. Such methods include the use of cellular automata and agent-based modelling (Flake, 2001) to model complex systems such as cities (Batty, 2005).

If this vision of geocomputation is nomothetic and law-seeking, does it then risk the...
criticisms of positivism, which have been used as the stick to beat other areas of quantitative, computational and spatial scientific human geography? Not necessarily. For example, if we accept the proposition that visualization of pattern suggests insight into the processes that generate that pattern (e.g. Batty and Longley, 1994), and if the researcher goes beyond what is empirically observable to ask questions and form concepts about the more fundamental structures and mechanisms for the events or phenomena under study, then the tenets of realism or critical realist philosophies are approached (Danermark, Ekström, Jakobsen and Karlsson, 2001).

Is, then, Couclelis (1998, p. 22) still right to say that geocomputation has ‘no [single] philosophy (and proud of it!)’? Perhaps so. Perhaps, desirable so. For, as computers and computation develop and evolve, new opportunities are presented for innovative geographical problem solving, alternative expressions of geographical enquiry and fresh geographical theorization, explanation and understanding. A few years ago the character of geocomputation could be conveyed by specifying what it was not: it was not simply geographic information systems but, rather, a reaction to the (then) limited geometric data manipulations and mapping capabilities offered by GIS. What was sought was the flexibility for more sophisticated and creative spatial statistical analysis, data visualization, process modelling and dynamic simulation that broke out of the GIS straightjacket. These various domains of geocomputation – spatial analysis, geovisualization, geosimulation and the application of artificial intelligence for geographical problem solving and knowledge discovery – still characterize geocomputation. But the ‘definition’ by counterfactual has begun to age, as interoperability and the ability to customise GIS have led to more sophisticated geocomputational methods to be implemented within a GIS environment (Maguire, Batty and Goodchild, 2005).

Nevertheless, new technologies could also yield a clearer identity for geocomputation. Computational ‘grid’ technologies – an allusion to electricity power grids – offer the opportunity for researchers to ‘plug in’ to high-performance computer networks under the rubric of ‘e-’ (electronic) social science. Martin (2005) identifies four essential research issues for e-sociR: automated data mining; visualization of spatial data uncertainty; incorporation of an explicitly spatial dimension into simulation modelling; and neighbour-ood classification (see geodemographics) from multi-source distributed data sets. These, he argues, could each be considered as important elements of a grid-enabled, geocomputational toolkit. It is this potential to contribute to the new e-science research environments that may crystallize geocomputation as a distinct research field spanning geography and related disciplines.

godemographics Geodemographics is ‘the analysis of people by where they live’ (Sleight, 2004) or, more precisely, by a data-based classification of residential location (although classifications have also been produced for workplace, financial services and cyberspace). The origins of geodemographics include Charles Booth’s poverty maps of London (1898–9; see http://booth.lse.ac.uk) and the 1920s–1930s Chicago School of urban sociology. During the twentieth century, the increasing availability of national census data and the development of computation permitted multivariate summaries of census zones to be produced, and for those areas to be grouped together on a like-with-like basis using clustering techniques (see classification and regionalization).

Those methodological developments provided the foundation for modern geodemographics – a major industry used by corporate, governmental, non-profit and political groups to deliver key advertising and services to their audiences, customers and users (Weiss, 2000). Commercial applications emerged during the late 1970s with the launch of PRIZM, by Claritas, in the USA and ACORN, by CACI, in the UK. Today’s classifications include not only census data, but also shopping, electoral, financial and other data about the ‘objects’ to be classified (commonly individuals, households, postcodes, Zip codes, census tracts or electoral wards). ACORN currently categorizes 1.9 million UK postcodes into one of five, seventeen or fifty-six types (plus some ‘unclassified’), using over 125 demographic statistics and 287 lifestyle variables. PRIZM NE incorporates both household and census data to describe, for example, Beverley Hills 90210 as containing ‘Blue Blood Estates’, ‘Bohemian Mix’ and ‘Money & Brains’ (amongst other segments). There are geodemographic classifications of most of Western Europe, Northern America, Brazil, Peru, Australasia, South
Africa, parts of Asia and some of China, including Hong Kong.

Many geographers have been active in developing geodemographic classifications, including Super Profiles (Charlton, Openshaw and Wymer, 1985), GB Profiles and a freely downloadable classification of UK Census Output Areas (at http://neighbourhood.statistics.gov.uk). Others have been more critical. One concern is that for some applications the cluster groups are not sufficiently homogeneous for them to represent well the individuals (or households) allocated to them. Voas and Williamson (2001) suggest that apparent differences between geodemographic classes conceal a much greater diversity within the classes. A related concern is that the montage of variables forming a geodemographic classification creates something of a black box, making it hard to determine the key predictors of the geographical phenomena being analysed. Care needs to be taken when interpreting geodemographic outputs because they are usually indexed as rates in one cluster, relative to all others. To find that an event is of above average prevalence in one geodemographic group is no guarantee that it is common there: the result could apply to a small minority of the population but still a larger proportion than for other clusters.

Surrounding geodemographics are broader debates in human geography, including those about REPRESENTATION, quantitative methodologies, EMPIRICISM, generalization, INDUCTION versus DEDUCTION, data- versus theory-led approaches to understanding, NEO-LIBERAL economies and the politics and commercialization of data collection, privacy and social discrimination. Critical theorists have cited geodemographics as an example of 'software sorting', suggesting that the sorts of labelling used in geodemographic systems can produce stigmatization of certain places and potentially deny them the same level of (e.g. banking or insurance) service given to other NEIGHBOURHOODS (Burrow, Ellison and Woods, 2005). However, the argument cuts two ways: geodemographics can also identify areas of social or material need, offering opportunity to better target the resources available to those places.

Geodemographic classifications can be used to interpolate market research and other survey data to standard administrative or ad hoc geographies allowing, as examples, estimation of: the levels of consumption of grocery products by supermarket catchment; demand for particular makes of car by dealership territory; or likely levels of diabetes by GP surgery catchment area. Whereas much academic debate centres on the accuracy (or otherwise) of geodemographics for predicting the behaviour of individuals, in practice many users are interested in aggregate behaviour – What, on average, is the most likely event, characteristic or behaviour at an area level, and how does this differ from other areas?

Increasingly, uses of geodemographics bring together academic, public policy and private-sector stakeholders, applying geographical thinking to tackle questions of social concern. Geodemographics has stimulated a renaissance in applied geographical research, being recently used for investigating the spatial distributions of family names, predicting spatial variation in pupils’ school examination performances, examining inequalities in hospital admissions and for guiding local POLICING (all at www.spatial-literacy.org).

Geographic Information Science (GISC) In the simplest sense, Geographic Information Science (GISC, or GIScience) is the theory that underlies GEOGRAPHIC INFORMATION SYSTEMS (GIS). The latter are the collection of hardware, software, output devices and practices that are used to analyse and map spatial entities and their relationships. GIS software might be used to determine the BOUNDARIES that distinguish areas with different average income levels in a city or a map of optimal delivery routes for a courier company. These results are, however, not transparent; the process through which they are derived are known as black box. Geographic Information Science – or the theoretical basis for GIS – is concerned with how results are obtained in GIS and what questions can legitimately be asked.

GIScience explores how spatial objects become digital entities, what effect that transformation has on their digital ontology, how different EPISTEMOLOGIES affect ontological REPRESENTATION, how to model relationships between spatial entities, and how to visualize them so that human beings can interpret the results (Raper, 1999). This pursuit draws on and extends developments in data modelling, computer science, cognition, VISUALIZATION and a myriad fields that have emerged in response to information systems.

For the first several decades of GIS use, little attention was given to the differentiation between geographical information systems
and SCIENCE. By the beginning of the 1990s, however, there was a sense among academic researchers that GIS had forged new intellectual territory. The term ‘GIScience’ was first used in a keynote speech given by Michael Goodchild during the July, 1990 Spatial Data Handling conference in Zurich. Goodchild noted that the GIS community is driven by intellectual curiosity about the representational and analytical capacity of Geographic Information Systems. He argued that GIS researchers should focus on fundamental precepts that underlie the technology rather than the application of existing technology. Furthermore, he argued that there are unique characteristics of spatial data, and problems associated with their analysis, that differentiate GIS from other information systems. These properties include: the need to develop conceptual models of space; the sphericity of spatial data (based on the shape of the Earth); problems with spatial data capture; spatial data uncertainty and error propagation; as well as algorithms and spatial data display. Given the distinctiveness of geographical data analysis and a growing community of researchers dedicated to solving technical and theoretical problems associated with GIS, Goodchild argued that ‘GIS as a field contains a legitimate set of scientific questions’. Goodchild’s keynote address was followed by a summary article in the International Journal of GIS (IJGIS) in 1992. This oft-cited article (Abler, 1993b; Dobson, 1993), was a beachhead for the very successful effort to change the meaning of the ‘S’ word in GIS (Goodchild, 1992).

The GIScience acronym subsequently garnered widespread support in most parts of the discipline. The name shift is manifest in other areas of geography. Progress in Physical Geography routinely presents updates on GIScience rather than GISystems (Atkinson, 1997). The flagship journal IJGIS was renamed International Journal of Geographical Information Science in January 1997; its editor, Peter Fisher, stressed that IJGIS had, in ten years of publication, predominantly reflected the development of theoretical bases that underpin subsequent systems: the science on which subsequent systems are based. Fisher turned to the (shorter) Oxford English Dictionary to support this distinction, noting that SYSTEMS are a collection of related objects or an assemblage while science is defined as knowledge obtain through investigation. He noted that the International Geographical Union (IGU) had developed a working group for Geographical Information Science in 1996, the implication being that there is broad institutional support for this designation (Fisher, 1997). Marc Armstrong, the former North American editor of IJGIS, recalls that identifying aspects of GIS as science was an acknowledgement that many GIS researchers were neither using nor developing ‘systems’, but were doing basic theoretical work that involved the ‘systematization’ of knowledge (Armstrong, pers. comm.). Despite a call for recognition of the scientific value of GIS, on the part of the academic community, the technology is indisputably social in its construction, especially at the software level.

Questions about the underlying assumptions written into the code that comprises GISystems are the basis of GIScience. GIScientists might legitimately question, for example, the premises of embedded algorithmic models. A hydrological model, for instance, might be outdated and fail to reflect current understanding of flow processes. Queries about the assumptions of the model creators, their efficacy in multiple environments, and whether they are designed for use with VECTOR (polygon) or RASTER (gridded) data all fall in the realm of GIScience. These types of questions strike at the efficiency and legitimacy of current Geographic Information Systems ALGORITHMS; their resolution is the basis for increase in the reliability of GIS for the average user. Such questions do not represent the entirety of GIScience, however.

Every stage of GISystems, from spatial data collection and input, to storage, analysis and, finally, output of MAPS, is based on the translation of spatial phenomena into digital terms. At each step of GIS, data are manipulated for use in a digital environment, and these, often subtle, changes have profound effects on the results of analysis. Each of these transformations involves a subtle shift in the representation of spatial entities, and accounting for these modifications and their implications is an important part of GIScience. Physical and social information about the world, once in digital form, is often manipulated and analysed in order to correspond to the researcher’s interpretation of the world. Thus it is of fundamental importance that GIScience develop methods to monitor and account for the effects that possible transformations have on final representation. Finally, GIScience researchers are charged with developing methods of presenting analysis results such that their visual display is consistent with database results.
GIScience is concerned theoretically with every stage of digital representation. Spatial phenomena must be delineated and classified in preparation for input to data tables. Classification systems, however, must be compatible with data tables, and this acts as a constraint to the development of categories. Many spatial phenomena manifest multiple characteristics, but not all of them can be included in a database or the data would be infinite. The manipulation of data depends on the attributes that are recorded, or the objects that are defined. Different community boundaries, for instance, will render different results in an assessment of population health. Visualizing GIS results is likewise vulnerable to the vagaries of the digital environment, and must be consistent with human capacity for perception. At a small scale (larger area), for instance, only a limited number of attributes can be displayed or the map becomes overcrowded. At a larger scale (smaller area), a greater number of attributes can be accommodated. Each of these issues has a bearing on how spatial data are analysed and interpreted.

The GIScience research purview is the representation of spatial data and their relationships and these are ultimately expressed in terms of bits and bytes. Working in a digital environment is akin to speaking another language that uses fundamentally different building blocks. If we think of the English language as being composed of twenty-six letters that can be combined in various ways to form words, sentences and ideas, then GIS is based on two letters or digits – zeros and ones – that can be combined and manipulated to represent and analyse geographical phenomena and relationships. But the environment and rules associated with manipulating geographical objects are quite different from those we are accustomed to using for conventional text and graphics. The digital environment is constrained by digital parameters and the extent of representation possible through combinations and permutations of bits and bytes.

GIScience is not limited, however, to process-oriented issues. It is engaged with how people represent their geographical environment, and who has the authority to represent space. Public Participation GIS (PPGIS) studies and engages with non-profit groups and non-governmental organizations that use GIS to represent themselves, and advocate for change (Elwood and Leitner, 2003). Other GIScientists address questions about feminism and GIS, and whether the technology is inherently gendered (Kwan, 2002). Stacey Warren (2004) explains that PPGIS and feminism and GIS allow us to move the focus from analysis and representation in GIS to one that views the technology as a ‘collaborative process that involves both people and machinery’. This emphasis on social interactions between users, affected populations, and technology is evident in the growing number of Critical GIS scholars who have merged emancipatory agendas and theory from human geography with GIScience.

Developers and researchers postulate that GIScience transcends mere information systems and allows users to ask questions about spatial relations that were previously impossible to pose. Its champions argue that Geographic Information Science extends spatial analysis by virtue of enhanced processing power that allows data-intensive analyses to extend their geographical breadth. They claim that GIScience is a means of investigating previously obscured spatial relationships and contingencies. There is a tension between GIS scholars who view the technology as an emergent phenomenon, capable of initiating a shift in scientific methodology and other geographers who view it simply as a vehicle for concepts that emerge from geography. It is, of course, both.

**Geographic Information Systems (GIS)** In the simplest terms, GIS (or GISystems) is the mix of hardware, software and practices used to run spatial analysis and mapping programs. GIS does not refer to a homogenous entity, nor one machine or a single practice but to a collection of practices, software and hardware with the ability to collect, store, display, analyse and print information about the Earth’s surface (or any other scale of geographical data). Each such system is able to capture, store, check, integrate, analyse and display spatially referenced data about aspects of the earth. GIS allows the combination of geographical data sets (or layers) and the creation of new geospatial data to which one can apply standard spatial analysis tools. Comprehensive GIS require a means of: (i) data input, from maps, aerial photos, satellites, surveys and other sources (cf. remote sensing); (ii) data storage, retrieval, and query; (iii) data transformation, analysis and modelling, including spatial statistics; and finally
(iv) data reporting, such as maps, reports and plans.

The GIS acronym has tended to focus on the software developed by specific corporations with less attention to the spatial data that are the basis for knowledge generation. Geographical information is information about where something is or what is at a certain location. For example, we may have data from a forest on where some of the few remaining spotted owls live – which is geographical information. What trees grow in the areas inhabited by the owls is also geographical information, because it has a spatial component. Spatial data are any data that have a location that can be geocoded. Increasingly, data from most domains include spatial data.

GIS are uniquely integrative. Where spatial data are available, GIS can offer a range of functionality. Whereas other technologies might be used only to analyse aerial photographs and satellite images, to create statistical models or to draft maps, these capabilities are all offered together within a comprehensive GIS. With its array of functions, GIS should be viewed as a process rather than as merely software or hardware. To see GIS as merely a software or hardware system is to miss the crucial role it can play in a comprehensive decision-making process.

GIS has different uses and meanings among a range of users. Municipalities, for instance, view GIS as the software that allows planners to identify residential, industrial and commercial zones – and store tax information. It maps the exact location and survey coordinates of each taxable property, and provides answers to queries such as: ‘How many properties would be affected by the addition of an extra lane to Highway 1 between 170th and 194th Streets?’ Population health researchers, on the other hand, may use GIS to define the boundaries of communities that enjoy varying health outcomes. In this instance, GIS is not a piece of software, but a scientific approach to the problem: ‘How do we define crisp boundaries to demarcate fuzzy and changeable phenomena?’ (cf. fuzzy sets). The latter is a fundamentally philosophical issue that must be resolved through computing and its answer lies somewhere between GIS and the underlying theory of geographic information science. These two types of users have different goals and experiences of GIS. One is interested in ‘where’ spatial entities are or might be, while the other is concerned with ‘how’ we encode spatial entities (e.g. communities, urban/rural areas, forests, roads, bridges and anything that might appear on a map), and the repercussions of different methods of analysis on answers to geographical questions. The diversity of GIS use is rooted in its history.

The development of GIS began in the 1960s, when the technology and epistemology that underlie it were first being developed. Methods of computerizing cartographic procedures were coincident with the realization that mapping could segue neatly into analysis. In 1962, Ian Harg, a landscape architect, introduced the method of ‘overlay’ that was later to become the defining methodology of GIS. He was searching for the optimal route for a new highway that would be associated with suburban development. His goal was to route the highway such that its path would involve the least disruption of other ‘layers’ of the landscape, including forest cover, pastoral valleys and existing semi-rural housing. He took multiple pieces of tracing paper, one representing each layer, and laid them over each other on a light table. By visually examining their intersections, he was able to ‘see’ the only logical route. Ironically, none of McHarg’s initial analysis was done using a computer. The metaphor of overlay was, however, integrated into early GIS, and became the basis for a range of analytical techniques broadly known as ‘spatial analysis’.

Spatial analysis is differentiated from ‘mapping’ because it generates more information or knowledge than can be gleaned from maps or data alone. It is a synergistic means of extracting information from spatial data. In the early development stages of GIS, however, few people recognized the power of analysis, and the technology was generically referred to as ‘computerized cartography’. As such, GIS was unimpressive. Early computerized maps were very primitive compared to the exquisite maps produced through manual cartography. This comparison led to reluctance among geographers to adopt GIS as a ‘substitute’ for traditional cartography.

The questionable aesthetic merit of traditional maps was, however, a detraction from the power of computerized spatial analysis. That power was first explored in universities in the late 1950s and early 1960s. Influenced by the quantitative revolution and the development of computers, researchers began to develop tools that could be used to analyse and display spatial data – though not always in map form. One of the earliest computer cartography systems was developed in Canada, the brainchild of Roger Tomlinson and Lee Pratt. Tomlinson had been using aerial photography...
to map forest cover in order to recommend locations for new growth; Pratt worked for the Canadian Ministry of Agriculture, which wanted to compile land-use maps for the entire country, maps that would describe multiple characteristics including agriculture, forestry, wildlife, recreation areas and census divisions. Tomlinson suggested that they pioneer a computerized system in which land-use zones were digitally encoded so that they could be overlaid with other relevant layers such as urban/rural areas, soil type and geology. This happenstance meeting led, in 1964, to the Canada Geographical Information System (CGIS). The name of the system was bestowed by a member of the Canadian Parliament.

There were parallel developments in Europe. Tom Waugh, for example, developed an early GIS system with the acronym GIMMS. It was a vector-based GIS system with sophisticated analysis, and was eventually used in twenty-three countries (Rhind, 1998). GIMMS preceded ESRI (see below) in developing a commercial GIS and was relatively sophisticated for the 1970s and 1980s – including cartographic options and batch processing. In the USA, the Harvard Graphics Laboratory was a tinderbox of the GIS revolution. Research at the laboratory established an efficient method for computerized overlay using polygon (vector) boundaries. The laboratory was populated by a host of researchers who had a profound influence on the development of current GIS, including Nicholas Chrisman and Tom Poiker. A diaspora of researchers from the Harvard Laboratory in the 1970s contributed to the dissemination of GIS, especially into the private sector. Scott Morehouse, a junior member, left in 1981 to work for a company in California called Environmental Systems Research Institute (ESRI), where he re-developed the algorithm for vector overlay which became a cornerstone of the program ARC/INFO. This dispersion of ideas from the Harvard Laboratory was the beginning of one GIS identity: that linked to software packages, hardware systems and technology in general (Chrisman, 1988).

Institutional and governmental support for GIS was also a major impetus for its growth and adoption from the 1970s onward. In the UK, four multidisciplinary Regional Research Laboratories (RRLs) were designated by the Economic and Social Research Council. They were designed to facilitate primary functions of GIS, including spatial data management, software development, spatial analysis and training of GIS researchers (Masser, 1988). In the USA, the National Center for Geographic Information Analysis was funded by the National Science Foundation (NSF). Three US universities with GIS expertise were chosen as primary research centres. Their role was to facilitate understanding and implementation of geospatial methodologies and develop university adoption of these techniques. The NCGIA also played an important role in hosting and responding to epistemological and pragmatic critiques of the technology (Pickles, 1995b; Curry, 1998).

The development of GIS, however, is not rooted solely in computer laboratories and universities in the latter part of the twentieth century. It is also an outgrowth of attempts to automate calculation in the nineteenth century reflected in efforts, for example, to code population data for the US census in 1890 (Foresman, 1998). Pre-eminent GIS scholar Michael Goodchild makes the point that GIS was developed during a period when information was increasingly being translated into digital terms and disseminated widely (Goodchild, 1995). If geographers had not explored the possibilities of digital manipulation of spatial data, other disciplines would have initiated the process. As it is, many roots of GIS are in disciplines other than geography including landscape architecture and surveying. Like all technologies, GIS is an outcome of both social and technological developments. NS

gEOGRAPHICAL EXPLANATION MACHINE (GEM)
An example of automated spatial data analysis catalysed by three factors: the growing availability of digital data with point \((x, y)\) geocoding; a move from statistical techniques ‘smoothing over’ geographical variation to local statistics revealing geographical patterns in data; and increased computational power to guide where to look. GAM passes a moving window of fixed radius (or population count) across a study region, repeatedly testing for unusual clusters of a particular feature. Successfully used to study the clustering of cancers, GAM and its primary architect – Stan Openshaw – inspired much of the research in geocomputation.

Suggested reading

gEOGRAPHICAL EXPLANATION MACHINE (GEM)
Whilst the GEOGRAPHICAL ANALYSIS MACHINE...
disCOVERs spatial patterns in geographical data sets, the geographical explanation machine tries to ‘explain’ them by identifying predictor variables with a spatial distribution matching the patterns found. As a tool for computer-assisted learning, GEM is pioneering. The problem, however, is that looking hard enough through sufficient data sets – as a computer can – will probably reveal an association although not necessarily one with scientific or rational meaning. Many geographers will baulk at an approach to social scientific explanation that is so avowedly empiricist and not guided by theory. Perhaps the ‘E’ in GEM could better be described as exploration. **geographical imaginary** A taken-for-granted spatial ordering of the world. ‘Imaginary’ is a concept derived from psychoanalytic theory, in particular the work of Jacques Lacan and Cornelius Castoriadis, and in its original versions it implied a sort of primitive or ur-geography: ‘The imaginary is the subject’s whole creation of a world for itself’ (Castoriadis, 1997; cf. Gregory, 1997a). In human geography, a ‘geographical imaginary’ is typically treated as a more or less unconscious and unreflective construction, but it is rarely given any formal theoretical inflection. It usually refers to a spatial ordering that is tied either to the collective object of a series of imaginative geographies (e.g. ‘the geographical imaginary of the Tropics’; see tropicality) or to their collective subject (e.g. ‘the imperial geographical imaginary’). Watts (1999) brilliantly combines the two in an exceptionally careful reconstruction of the ways in which the Ogoni people of the Niger delta fashioned a precarious sense of collective identity tied to space, territory and land. Like Watts, most studies recognize the crucial importance of language, especially metaphor, and of visuality in producing these orderings.

Geographical imaginaries involve bordering as well as ordering: the hierarchical division of the globe into continents, states and other sub-categories (see scale), for example, and the oppositions between global north/south, urban/rural, inside/outside and culture/nature. These divisions also often act as tacit valorizations (‘civilized’/‘savage’, for example, or ‘wild’/‘safe’) that derive not only from the cognitive operations of reason but also from structures of feeling and the operation of affect. As such, geographical imaginaries are more than representations or constructions of the world: they are vitally implicated in a material, sensuous process of ‘worlding’. Thus, for example, Howitt (2001a, pp. 236–7) identified a geographical imaginary that was intimately involved in the European construction of a ‘bounded self’ and which, in the colonial past of Australia and on into its present, worked to construct equally bounded spaces ‘that provided certainty, identity and security’ from which indigenous peoples were excluded. More generally, but closely connected, Massey (2004, pp. 9–10) attributed a pervasive ‘Russian-doll geography of care and responsibility’ to ‘the persistence of a geographical imaginary which is essentially territorial and which focuses on the near rather than the far’. It follows that a vital critical task for human geography is the disclosure of these taken-for-granted geographical imaginaries and an examination of their (often unacknowledged) effects. DG

Watts (1999).

**geographical imagination** A sensitivity towards the significance of place and space, landscape and nature, in the constitution and conduct of life on Earth. As such, a geographical imagination is by no means the exclusive preserve of the academic discipline of geography. H.C. Prince (1962) portrayed it as ‘a persistent and universal instinct of [humankind]’. The geographical imagination as he saw it was a response to places and landscapes, above all to their co-mingling of ‘culture’ and ‘nature’, that ‘calls into action our powers of sympathetic insight and imaginative understanding’ and whose rendering ‘is a creative art’ (cf. Cosgrove, 2006b). Prince’s emphasis on art and, by implication, on geography’s place among the humanities, was in part a critical response to the reformulation of the discipline as a spatial science. To Prince, these formal abstractions were ingenious and inventive but, ‘like abstract painting’, they would always remain indirect approaches to a world to which the freshest, fullest and richest response was, in his view, literary (whereas Cosgrove, who was profoundly sympathetic to Prince’s vision, made a compelling case for a visual and aesthetic sensibility – though he expressed this in luminous prose too). In Prince’s view, it was vitally important to preserve ‘a direct experience of landscape’ through the art of geographical description (see also representation).
Some ten years later, David Harvey (1973) provided a discussion of the geographical imagination that also recognized the value of the aesthetic, but Harvey departed from Prince’s account in two particularly significant ways: Harvey’s critique of spatial science was much more open to formal theoretical vocabularies (indeed, it relied on them), and its characteristic emphasis was on place and space rather than landscape and nature (which had occupied a much more prominent position in Prince’s discussion). In Harvey’s eyes, therefore, the geographical imagination enables ‘individual[s] to recognize the role of space and place in [their] own biographies, to relate to the spaces [they] see around [them], and to recognize how transactions between individuals and between organizations are affected by the space that separates them . . . , to judge the relevance of events in other places . . . , to fashion and use space creatively, and to appreciate the meaning of the spatial forms created by others’. Harvey wanted to contrast the geographical imagination with, but also to connect it to, what sociologist C. Wright Mills (1959) had called ‘the sociological imagination’, a capacity that ‘enables us to grasp history and biography and the relations between the two in society’. Neither Harvey nor Mills confined the terms to their own disciplines; they both said they were talking about ‘habits of mind’ that transcended particular disciplines and spiralled far beyond the discourse of the academy. Nonetheless, much of the discussion that followed from Harvey’s intervention was concerned with formal questions of theory and method.

A central preoccupation was the articulation of social theory, broadly conceived, and human geography. ‘It has been a fundamental concern of mine for several years now,’ so Harvey (1973) had written, ‘to heal the breach in our thought between what appear to be two distinctive and indeed irreconcilable modes of analysis’, and he presented his seminal Social Justice and the City as (in part) a ‘quest to bridge the gap between sociological and geographical imaginations’. It was urgently necessary to humanize human geography, and ideas and concepts were drawn in from the humanities and (especially) the social sciences – in particular, from political economy, social theory and nominally ‘cultural’ disciplines such as anthropology and cultural studies. En route, however, it became clear that the reverse movement was equally important, sensitizing these other fields to a geographical imagination, because most of them took a so-called ‘compositional’ approach that had no interest in place or space (cf. contextuality). This was a challenging project, and it involved not only geographers but also original, vital contributions from other disciplines. Indeed, some of the most intriguing and influential spatializations were produced by scholars outside the formal enclosures of Geography: Foucault and Deleuze in philosophy, Giddens and Urry in sociology, and Jameson and Said in comparative literature. Some ten years after Social Justice, Harvey (1984) calibrated the magnitude of the collaborative, interdisciplinary theoretical task like this:

The insertion of space, place, locale and milieu into any social theory has a numbing effect upon that theory’s central propositions . . . Marx, Marshall, Weber and Durkheim all have this in common: they prioritize time over space and, where they treat the latter at all, tend to view it unproblematically as the site or context for historical action. Whenever social theorists of whatever stripe actively interrogate the meaning of geographical categories, they are forced either to make so many ad hoc adjustments to their theory that it splinters into incoherence, or else to abandon their theory in favour of some language derived from pure geometry. The insertion of spatial concepts into social theory has not yet been successfully accomplished. Yet social theory that ignores the materialities of actual geographical configurations, relations and processes lacks validity.

Subsequent commentators reported considerable progress in sensitizing social theory and social thought more generally to these concerns. There was (and remains) an immensely productive dialogue between Marxism and human geography, especially through economic geography and historical geography (see also Marxist geography), and these conversations and their critiques spilled over into a number of other politico-intellectual traditions (Harvey, 1990; cf. Castree, 2007). The rise of postmodernism was hailed as emblematic of a distinctively geographical (or at any rate ‘spatial’) imagination (Soja, 1989), and the interest in post-colonialism and post-structuralism contributed in still more radical ways to the critique of abstract and universal models of subject, society and space. But three other dimensions of the geographical imagination have received close attention in recent years, and each of them works towards the production of ‘impure’
geographies that depart considerably from the closures and clinical approaches of Geography-with-a-capital-G.

In the first place, there has been a renewed interrogation of academic versions of the geographical imagination, and in particular of the two versions proposed by Prince and Harvey (above). Influenced by post-structuralism in different ways and to different degrees, and in particular by a focus on geography as discourse, several critics have argued that geography is not simply framed by or reflective of changes in the ‘real’ world: on the contrary, its discourses are constitutive of that world. For Gregory (1994) and Deutsche (1995), drawing on Mitchell’s (1989) account of the world-as-exhibition, human geography is construed as ‘a site where images of the city and space more generally are set up as reality’, as fabrications in the double sense of imaginative works and works that are made, and hence as ‘the effects rather than the ground of disciplinary knowledge’ (emphasis added). Thus the modern geographical imagination, in its usual hegemonic form, not only ‘stages the world-as-exhibition and at the same time is fabricated by the picture it creates’; it also characteristically disavows its dependence by adopting an objectivist epistemology that separates itself from the picture as an autonomous, all-seeing ‘spectatorial’ subject (Deutsche, 1995). Such an epistemology is, as she remarks, a vehicle for ‘the silent spatial production’ of ‘the self-possessed subject of geographical knowledge who, severed from its object, is positioned to perceive an external totality and so avoids the partiality of immersion in the world’ (cf. situated knowledge).

Gillian Rose (1993) emphasizes that this is both an act of mastery – hence her critique of the masculinism of geographical knowledge – but also an act that is shot through with ambivalence:

In geography, a controlling, objective distance is not the only relationship which positions the knower in relation to his object of study. There is rather an ambivalence, which produces the restlessness of the signifiers within the discipline’s dualistic thinking. On the one hand, there is a fear of the Other, of an involvement with the Other, which does produce a distance and a desire to dominate in order to maintain that distance. This is central to social-scientific masculinism. On the other hand, there is also a desire for knowledge and intimacy, for closeness and humility in order to learn, and this is the desire of aesthetic masculinity to invoke its other. (Rose, 1993, p. 77)

Rose’s critique identifies the first position (‘social-scientific masculinity’) with projects such as Harvey’s and the second position (‘aesthetic masculinity’) with projects such as Prince’s.

Rose and Deutsche both urged that this recognition of the limits (rather than the presumed completeness) of geographical knowledge’s involve an engagement with psychoanalytic theory in order to grapple not with the conscious and creative exercise of the ‘imagination’ – something that concerned Prince (1962) in particular and humanistic geography in general – but with the imaginary: in other words, with ‘the psychic register in which the subject searches for plenitude, for a reflection of its own completeness’ (cf. geographical imaginary). By this means, Rose (1993, p. 85) suggests, it is possible ‘to think about a different kind of geographical imagination which could enable a recognition of radical difference from itself; an imagination sensitive to difference and power which allows others rather than an other’ (see also feminist geographies; queer theory). In the same spirit, experiments with non-representational theory may also be seen as creative attempts to apprehend the world in terms that are not limited to cognition and consciousness (see also affect).

In the second place, and closely connected to these departures, there has been a pluralization of geographical imaginations. Many human geographers have become reluctant to speak of ‘the’ geographical imagination – unless they are referring to a hegemonic form of geographical enquiry, and then usually as an object of critique – and are much more interested in the possibilities and predicaments that arise from working in the spaces between different philosophical and theoretical traditions (see Gregory, 1994). Closely connected to the production of these ‘impure’ geographies, there has also been a considerable interest in geographical knowledges that are not confined to (indeed, have often been excluded from) the formalizations of the academy. The boundaries of geography have thus been called into question through the recovery of quite other imaginative geographies that can have extraordinary powerful effects (cf. performativity); for example, the geographical imaginations deployed to wage war (see military geography), conveyed through travel
Writing, or mobilized in popular culture and politics (e.g. Pred, 2000). Critical studies of these geographical imaginations are not being conducted in an annex to the central structures of geography. Not only are they informed by contemporary politico-intellectual preoccupations but they also contest the conventional partitions between ‘high’ and ‘low’ cultures and imaginations. The circulation of discourses in and out of academic institutions is of vital importance to the elucidation of the politics of geographical imaginations, but also to their conduct: hence the interest in public geographies that transcend a narrow, instrumental concern with policy formulation to address political issues within a wider public sphere. A number of these contributions have been informed by post-colonialism, which has inspired a belated recognition of the whiteness of dominant geographical imaginations and the importance of geographical imaginations outside the global north (see anglocentrism; ethnocentrism; eurocentrism).

Third, there has been a renewed engagement with ‘nature’. The impetus for this has come from outside the discipline as much as from within, through precisely the political engagements and public, ‘popular’ geographies identified in the last paragraph. And yet in the previous paragraphs ‘nature’ has effectively been displaced from the central position it was once accorded within most major traditions of geography and its place taken by space. The price paid for the articulation of a distinctively ‘human’ geography in the wake of what many critics saw as a dehumanizing spatial science was ‘a peculiar silence on the question of nature’ (Fitzsimmons, 1989). This has changed dramatically in recent years. These newer formulations do not eschew the signficance of space – on the contrary, often informed by actor-network theory, they elaborate a topological ‘spatial imagination’ – but they do so in ways that produce a much more sensuous, lively geographical imagination. For they ‘alert us to a world of commotion in which the sites, tracks and contours of social life are constantly in the making through networks of actants-in-relation that are at once local and global, natural and cultural, and always more than human’ (Whatmore, 1999b, p. 33). Such an approach, as Whatmore notes, ‘implicates geographical imaginations and practices both in the purifying logic which ... fragments living fabrics of association and designates the proper places of “nature” and “society”, and in the promise of its refusal’ (p. 34; emphases added). To fulfil such a promise, critical enquiry will require the production of radically ‘impure’, heterogeneous geographies. The philosopher A.N. Whitehead once famously remarked, ‘Nature doesn’t come as clean as you can think it.’ And for the reasons spelled out in these paragraphs, many would agree that geographical imaginations are – at last – becoming much dirtier.

All that said, there are two further dimensions of geographical imaginations that have received rather less attention, and both return us to the concerns originally voiced by Prince and Harvey. On one side, there have been attempts to experiment with forms of geographical expression – to realize the imaginative capacities and creative potential of geography in something like the sense that Prince used the term, the sort of sensibility that invites a reaction of surprise, even wonder: ‘I’ve never thought of the world like that before.’ Most of these have been confined to linguistic play in the pages of academic journals or monographs, however, though some human geographers have been drawn to the possibilities of art installations and dramatic performances as ways to reach wider audiences in non-traditional, non-academic forms. Without this outreach, which will almost certainly also involve the imaginative use of new technologies of communication, the possibility of public geographies will remain just that – a possibility. On the other side, and closely connected to this concern, there have been remarkably few attempts to imagine other worlds in the sense that Harvey (2000b) gave the term: ‘spaces of hope’. This too is crucial; the transformations and extensions of geographical imaginations described above, and throughout this Dictionary, reveal an extraordinary capacity within and beyond the discipline for critique, for the pursuit and even the privileging of what Benhabib (1986) identified as the explanatory-diagnostic. But, as she also shows, a genuinely critical enquiry must also include the anticipatory–utopian (see utopia): without releasing and realizing our geographical imaginations in this vital sense, then, we will turn forever on the treadmills of somebody else’s present. geographical societies Voluntary organizations, some of them professional, whose goal is the promotion of geography as a subject and/or an academic discipline.
The early and middle nineteenth century saw the formation of several societies in the former category – both national (the Royal Geographical Society – RGS – and the American Geographical Society – AGS, for example) and local (e.g. the Manchester Geographical Society). Set within the context of a massive expansion of trade – associated with colonialism, imperialism and militarism (Driver, 1998) – the societies promoted exploration, by financing expeditions and the dissemination of their findings, and cartography, to represent the ‘new worlds’ that were mapped. Some of that dissemination was focused on commercial and government users (cf. commercial geography), but the societies also popularized geography, through their lecture programmes and publications. Some continue both functions. In their popularizing role they have been joined by others, such as the National Geographic Society, whose National Geographic Magazine sells millions of copies each month: similar magazines are produced as commercial ventures, such as New Zealand Geographical and the Geographical Magazine, now called simply Geographical, which is owned by the RGS.

In the late nineteenth century, many of these societies identified the need for geography to be included in school curricula, as part of children’s general education as world citizens as well as a means of promoting national identity (cf. nationalism). They were more successful in some countries (notably the UK and several in continental Europe) than others (the USA, for example: Schulten, 2001). They then turned their attention to their countries’ universities, seeking to have the discipline taught there in order to ensure an adequate supply of trained teachers and others knowledgeable about geography and its techniques: the RGS funded the initial appointments at Oxford and Cambridge, for example, and also provided support to fledgling departments at Aberystwyth, Edinburgh and Manchester (Johnston, 2003).

With the establishment of geography as a school and university subject, separate professions were created and societies formed to promote geographers’ interests: for school teachers, for example, these included the Geographical Association in the UK and the National Council for Geographic Education in the USA. In the universities, the research culture was nurtured by professional learned societies such as the Association of American Geographers (AAG) and the Institute of British Geographers (IBG), whose main functions were to hold conferences and other meetings and to publish journals and monographs. These learned societies operated largely independently of the longer-established societies with their wider briefs, although the AGS provided much early support for the AAG: the IBG and RGS merged in 1996.

Identification of geography as an important subject in contemporary society and then the creation and continued existence of the academic discipline owes much to the pioneering and continued efforts of these societies – critical ‘spaces of science’ in Livingstone’s (2003c) geographies of scientific knowledge (see science). The societies are major nexuses in the social networks through which academic geographers collaborate and promote their discipline – especially at a national level – and their journals are widely considered as among the leading media for the dissemination of and debate over research findings. geographically weighted regression (GWR)
Standard regression models, like most quantitative methods, fit an average relationship across all measured units; that is, an overall global model is fitted, thereby assuming that processes are constant over space. GWR, as proposed by Brunsdon, Fotheringham and Charlton (1996), is an exploratory data analysis technique that allows the relationship between an outcome and a set of predictor variables to vary locally across the map. The approach aims to find spatial non-stationarity and distinguish this from mere chance; as such it is a development of Casetti’s (1972) expansion method. With its emphasis on the potential importance of local contextuality, GWR is similar in intent to multi-level modelling: indeed, GWR-like models can be regarded as a specific type of multilevel model, the multiple membership model (Lawson, Browne and Vidal Rodeiro, 2003). As always, however, there is the danger that the results reflect not genuine spatial non-stationarity but, rather, simple misspecification, as when important predictor variables have been omitted from the model, with these variables themselves varying geographically.

The GWR technique works by identifying spatial subsamples of the data and fitting local regressions. Taking each sampled areal unit across a map in turn, a set of nearby areas
that form the ‘local’ surrounding region is selected, and a regression is then fitted to data in this region in such a way that that nearby areas are given greater weight in the estimation of the regression coefficients than those further from the sampled unit. This surrounding region is known as the spatial kernel or bandwidth; it can have a fixed spatial size across the map, but this could result in unstable estimation in some regions where there are relatively few areas on which to base the local regression, and possibly miss important small-scale patterns where a number of local areas are clustered together spatially. Consequently, an adaptive spatial kernel is often preferred, so that a minimum number of areas can be specified as forming the region and the kernel extends out until this number has been achieved. Changing the kernel changes the spatial weighting scheme, which in turn produces estimates that vary more or less rapidly over space. A number of techniques have been developed for selecting an appropriate kernel and testing for spatial stationarity (Leung, Mei and Zhang, 2000; Paez, Uchida and Miyamoto, 2002).

Once a model has been calibrated, a set of local parameter estimates for each predictor variable can be mapped to see how the relation varies spatially. Similarly, local measures of standard errors and goodness-of-fit statistics can be obtained and mapped. An increasing number of applications of GWR includes models of house price and educational attainment level variations. Software for GWR is available from the original developers at http://ncg.nuim.ie/GWR.

geography Literally, ‘earth-writing’ from the Greek geo (earth) and graphia (writing), the practice of making geographies (‘geographing’) involves both writing about (conveying, expressing or representing) the world and also writing (marking, shaping or transforming) the world. The two fold in and out of one another in an ongoing and constantly changing series of situated practices, and even when attempts have been made to hold ‘geo-graphing’ still, to confine its objects and methods to a formal discipline, it has always escaped those enclosures. In consequence, as Livingstone (1992, p. 28) insisted, ‘The idea that there is some eternal metaphysical core to geography independent of circumstances will simply have to go’. While the history of geography (see GEOGRAPHY, HISTORY OF) is neither bounded by its disciplinary formation nor the North Atlantic, recent historians of geography have paid close attention to the institutionalization of geography as a university discipline in Europe and North America from the closing decades of the nineteenth century onwards. This focus on the academy overlooks two important considerations. First, ‘the institutional and intellectual form of the university is itself a series of [situated] practices that have changed over time’: the present sense of a ‘discipline’ was alien to the early modern university, but this did not prevent the provision of instruction in both descriptive and mathematical geography (Withers and Mayhew, 2002, pp. 13–15). Second, like Molière’s M. Jourdain, who was astonished to learn he had been talking prose all his life without knowing anything about it, many geographers (and others) have produced what could be regarded as geographical knowledge in the course of enquiries that they construed in quite other ways. More than this, their reception within the discipline has been uneven. Some contributions have been recognized (and even appropriated) as geography, while others have been disavowed for nominally ‘professional’ reasons: so, for example, research in spatial statistics may be seen as central to the discipline by some geographers, while TRAVEL-WRITING may be rejected as the impressionistic work of the amateur. As these examples suggest, however, such evaluations are themselves necessarily historically contingent, and Rose (1995) has cautioned that disciplinary geography ‘has so often defined itself against what it insists it is not, that writing its histories without considering what has been constructed as not-geography is to tell only half the story’.

All boundary-drawing exercises are fraught with difficulties, therefore, and intellectual landscapes are no exception: such projects are never ‘only’ about ideas, but also about the grids of POWER in which they are implicated. The boundary question became intrusive with the creation of modern disciplines, and the inclusion of modern geography among them. Its disciplinary formation was a response to political and economic concerns (most viscerally, the demand for a MILITARY GEOGRAPHY in the service of modern WAR and, in the UK at least, a COMMERCIAL GEOGRAPHY to underwrite international trade) and also to pedagogical ambitions (the desire to transmit particular, nationalistic geographical knowledges through school curricula; see
The practical considerations were hardly unique to the nineteenth century. Geography had long articulated political and commercial interests – in the seventeenth century Varenius had emphasized the importance of Special Geography (or Regional Geography) to both ‘statecraft’ and the mercantile affairs of the Dutch Republic, for example – and it was already deeply invested in what Withers (2001) calls ‘visualizing the nation’. But its academic institutionalization raised questions about the distance between ‘professional’ and ‘popular’ geographies, and about the very possibility of geography as a field of scholarly research (rather than the compilation of others’ observations) that continue to resonate today. Soul-searching (or navel-gazing) about the ‘spirit and purpose’ or ‘nature’ of geography has become markedly less common in recent years, however, as the contingency and fluidity of intellectual enquiry have been embraced. There has been much greater interest in charting future geographies, whose variety confirms the radical openness of geographical horizons: there is no single direction, still less a teleological path, to be pursued (cf. Chorley, 1973; Johnston, 1985).

It follows that no definition of geography will satisfy everyone, and nor should it. But one possible definition of the contemporary discipline is: (The study of) the ways in which space is involved in the operation and outcome of social and biophysical processes. When it is unpacked, this summary sentence provides six starting-points for discussion:

(1) As the opening brackets indicate, ‘geography’, like ‘history’, has a double meaning: it both describes knowledge about or study of something (most formally, a discipline or field of intellectual enquiry) and it constitutes a particular object of enquiry, as in ‘the geography of soil erosion’ or ‘the geography of China’ (so that ‘soil erosion’ and ‘China’ have geographies just as they have histories). In fact, the relations between geography and history have long exercised philosophers. Classical Humanism distinguished between chorology and chronology, for example, orderings in space and orderings in time, while Enlightenment aesthetics asserted that the object of the visual arts (painting or sculpture) was the imitation of elements coexisting in space and that of the discursive arts (narrative poetry) the expression of moments unfolding in time. In the course of the twentieth century, disciplinary geography was increasingly troubled by both ways of making the distinction.

First, Hartshorne’s attempt to legislate The nature of geography (1939) had treated geography and history as non-identical twins born under the sign of Exceptionalism. They were held to be different from one another because they classified phenomena according to their coexistence either in space (geography) or in time (history), but this also made them both different from all other forms of intellectual enquiry, which classified phenomena according to their similarity to one another (see Kantianism). This, in its turn, was supposed to limit concept-formation in geography and history to particularity rather than generalization, to the idiographic rather than the nomothetic (which was the preserve of the sciences). These distinctions proved to be constant provocations. Most geographers insisted that time and history could not be excluded from geographical enquiry, and Hartshorne eventually conceded the point. Indeed, studies of landscape evolution, physical and cultural, were regarded as such mainstays of geographical enquiry that Darby (1953, p. 11) could describe geomorphology and Historical Geography as its twin foundations: even then, ‘space’ was not understood as a static stage. More than this, however, particularly after the Quantitative Revolution of the 1960s, the study of diffusion, the development of dynamic modelling and the capacity to capture the modalities of environmental and social change required any rigorous analysis of the concrete specificities of geographical variation to be informed by the theories and methods of the mainstream sciences and social sciences: geography could not be separated from other fields by philosophical fiat.

Second, the emphasis on geographical change raised what Darby (1962) called ‘the problem of geographical description’: How was it possible for a field that placed such a premium on the visual to convey any sense of place and landscape by textual means? Darby’s original sense of this reactivated that Enlightenment sensibility: ‘We can look at a picture as a whole,’ he wrote, ‘and it is as a whole that it leaves an impression upon us; we can, however, read only line by line.’ The question (and Darby’s way of framing it) later seemed problematic to many human geographers, who enquired more closely into practices of representation and interpretation. They examined the visual ideologies of cartography and the poetics of prose, for example, both the nominally objective prose of scientific enquiry.
that dominated geographical journals and more evocative modes of expressing places and landscapes. En route, geography’s connections with the humanities spiralled far beyond history, to include art history, dance, film studies, the literary disciplines, music and performance studies. These were more than exercises in critical interrogation or deconstruction; they also involved creative experiments in writing (see, e.g., Harrison, Pile and Thrift, 2004; Pred, 2004) and collaborations with artists, curators, film-makers and performance artists.

(2) These close encounters with the sciences, social sciences and humanities have ensured that there is no single paradigm or method of enquiry in geography. In order to elucidate the multiple ways in which space is involved in the conduct of life on Earth and in the transformation of its surface, geographers have been drawn into many different conversations: human geographers with anthropologists, art historians, economists, historians, literary scholars, psychologists, sociologists and others; physical geographers with atmospheric scientists, botanists, biologists, ecologists, geologists, soil scientists, zoologists and others. These conversations have varied through time, and the history of geography (see history of geography) is an important part of understanding how the contemporary field of geographical enquiry has come to be the way it is, marking both its ruptures from as well as its continuities with any presumptive ‘geographical tradition’ (Livingstone, 1992). These conversations have also varied over space, so that there is a ‘geography of Geography’ too. The same claims can be made about any discipline, but in geography they have been increasingly interconnected. Most recent studies of the history of geography have recognized the importance of the spaces in which geographical knowledge is produced and through which it circulates. This has involved attempts both to contextualize geography – to understand the development of geographical ideas in relation to the places and situations from which they have emerged and the predicaments to which they were responding – and to de-territorialize geography: to open the disciplinary ring-fence, to appreciate that geography is not limited to the academy and to interrogate the production of geographical knowledges at multiple sites (Harvey, 2004a).

These studies have produced a heightened sensitivity to the specificity and partiality of Anglo-American and, still more particularly, Anglo-American geography. Contracting geography’s long and global history, Stoddart (1985) proclaimed that modern geography was a distinctively European science that could be traced back to a series of decisive advances in the closing decades of the eighteenth century. It was then, so Stoddart argued, that ‘truth’ was made the central criterion of objective science through the systematic deployment of observation, classification and comparison, and in his view it was the extension of these methods from the study of nature to the study of human societies ‘that made our subject possible’. But the critique of the assumptions that underwrote such a claim, sharpened by the rise of post-colonialism, prompted many commentators to re-situate that project as a profoundly Eurocentric and, more recently, Euro-American science (see eurocentrism: Gregory, 1994). Geography has thus come to be seen as a situated knowledge that, of necessity, must enter into conversations with scholars and others who occupy quite different positions.

This is not only (or even primarily) a matter of interdisciplinary dialogue; it also implies inter-locational dialogue. The more restricted idea of an Anglo-American geography was largely a creature of the 1960s and 1970s when, at the height of the quantitative revolution, it seemed that a unified and coherent model-based geography was emerging on both sides of the Atlantic. ‘Theory’, too, seemed to offer a universal language that held out the promise of a unified, even unitary discipline. The subsequent critique of spatial science opened up many other paths for geographers to explore, and in that sense promoted diversification, but in human geography in particular it also heralded divergence as it prised apart the commonalities that once held the Anglo-American corpus together (cf. Johnston and Sidaway, 2004). This coherence (or rigidity, depending on your point of view) has also been assailed by a growing concern about the grids of power and privilege that structure the international academy, and in particular the silences and limitations of a narrowly English-language geography. If, as Wittgenstein observed, ‘the limits of my language mean the limits of my world’, then a geography that privileges one language is not only limited: it is also dangerous (Hassink, 2007). This poses an obvious difficulty for dictionaries of geography such as this one (cf. Brunotte, Gebhardt, Meurer, Meusburger and Nipper, 2002; Levy and Lussault, 2003).

That said, Anglophone geographers have not been wholly indifferent to work in other
languages. Hartshorne’s (1939) enquiry into the nature of geography was an exegesis of a largely German-language tradition, and British and American historians of geography have long acknowledged the foundational role of figures such as Alexander von Humboldt (1769–1859), Karl Ritter (1779–1859), Friedrich Ratzel (1844–1904) (see ANTHROPOGEOGRAPHY) and, in France, Paul Vidal de la Blache (1845–1918). From the closing decades of the twentieth century, however, as human geography took an ever closer interest in continental European PHILOSOPHY – Giorgio Agamben, Alain Badiou, Jacques Derrida, Michel Foucault, Martin Heidegger, Jürgen Habermas, Julia Kristeva and Henri Lefebvre have all occupied prominent positions in contemporary discussions – there was, until very recently, little or no equivalent interest in continental European geography (apart from the work of Nordic and Dutch geographers available in English). One of the ironies of Stoddart’s thesis about geography as a European science has been the extraordinary indifference of much of the Euro-American discipline to the multiple European genealogies of geographical discourse (cf. Godlewska, 1999; Minca, 2007b: see ANGLOCENTRISM). COLONIALISM and IMPERIALISM continue to cast long shadows over the discipline too: outside DEVELOPMENT GEOGRAPHY there has been a comparable lack of interest in the work of geographers from the global SOUTH (cf. Slater, 2004).

It is true that conferences under the auspices of the International Geographical Union and major national GEOGRAPHICAL SOCIETIES (especially the Association of American Geographers and also the Royal Geographical Society/Institute of British Geographers) attract participants from all over the world, but being together is not the same as talking together. Smaller, more focused meetings have usually been more successful at encouraging dialogue, and the activities of the International Critical Human Geography Group, the Aegean Seminars and international conferences in HISTORICAL GEOGRAPHY and ECONOMIC GEOGRAPHY have all helped to dissolve these parochialisms. But it has proved remarkably difficult to facilitate a less episodic, global exchange of ideas, and concern continues to be expressed about the HEGEMONY of English-language geography in nominally ‘international’ meetings and journals (Garcia-Ramon, 2003; Paasi, 2005). It may be that physical geographers have been more successful in resolving these issues, and that their ideas travel through more effective and multi-directional channels. Their main journals attract contributions from authors in many countries, and the International Association of Geomorphologists has promoted a series of international and regional conferences. But this apparent success may also reflect a problematic conviction that ‘science’ is itself an international and ‘interest-free’ language (cf. Peters, 2006).

(3) To make ‘space’ focal to geographical enquiry is not to marginalize PLACE, REGION or LANDSCAPE. These constructs have often been opposed in geography’s theory-wars, but while they are certainly different concepts with different entailments, genealogies and implications (all of which need to be respected) they all also register modes of producing SPACE as a field of differentiation and integration. To say this is to recognize geography’s dependence on a series of technical and theoretical devices. This was so even when geography was conducted under the sign of a supposedly naïve EMPIRICISM, what William Bunge and William Warntz once called ‘the innocent science’, because the production and certification of its knowledges involved a series of calculative and conceptual templates. Technically, the ongoing formation of geography has been intimately involved with the changing capacity to conceive of the Earth as a whole (Cosgrove, 2001) and to fix and discriminate between positions on its surface (in geodesy, navigation and the like), and thus with the development of CARTOGRAPHY and GEOGRAPHIC INFORMATION SYSTEMS (GIS) that provide compelling demonstrations of the relevance of ‘location, location, location’ to more than real estate sales (Pickles, 2004; Short, 2004). The history of these procedures is closely associated with that of EXPLORATION, the politico-economic adventures of CAPITALISM, the occupations and dispossession of COLONIALISM and IMPERIALISM, modern WAR and the deep interest of the modern STATE in the calculation and imagination of TERRITORY. To list these entanglements is not to imply a simple history of complicity, but this in its turn is not a plea for exculpation of ‘Geography Militant’ (Driver, 2001a): it is merely to note that many of these technical devices can be (and have been) turned to critical account, as the development of critical or radical cartographies and critical GIS attests (Harvey, Kwan and Pavouska, 2005; Crampton and Krygier, 2006), and to underscore that the ‘technical’ is never far from the political. These means of knowing and rendering
the world have been reinforced by formal theories about location, spatialization and interdependence that have offered an increasingly sophisticated purchase on geographies of uneven development and the variable intersections between capitalism, war and globalization (Smith, 2008 [1984]; Harvey, 2003b; Sparke, 2005). These formulations are themselves marked by their origins, and the privileges of location that they address – and incorporate (Slater, 1992) – have been underwritten by less formal but no less rhetorically powerful imaginative geographies that not only inculcate a ‘sense of place’ that is central to identity-formation and the conduct of everyday life, but also work to normalize particular ways of knowing the world and to produce allegiances, connections and divisions within it (Gregory, 2004b; see also geographical imaginaries).

By these various means, ‘space’ has been produced, at once materially and discursively, through a series of what are profoundly political technologies. Hence, for example, Pickles’ (2004, p. 93) pithy sense of the performativity of cartography: ‘Mapping, even as it claims to be reproducing the world, produces it.’ Attempts to understand these processes of production have involved historical accounts of the development of concepts and the systems of practice in which they have been embedded, in both physical and human geography (see, e.g., Beckinsale, Chorley and Dunn, 1964/1973/1991; Gregory, 2008). They have involved explorations of other versions of those spatializations too: experiments with different concepts of landscape, place, region and space itself (see, e.g., Holloway, Rice and Valentine, 2003). In the same vein, there have been repeated forays into the vexed question of scale, which most physical geographers – in the wake of Schumm and Lichty’s (1965) classic essay – seem to regard as the very skeleton of their subject (Church and Mark, 1980), while at least some human geographers see it as the disarticulation of theirs (cf. Sheppard and McMaster, 2004; Marston, Jones and Woodward, 2005). The interrogation of these concepts has been an increasingly interdisciplinary project – none of them is the peculiar possession of geography, even if geographers have done their most characteristic work with the tools they provide: ‘Space is the everywhere of modern thought’ (Crag and Thrift, 2000, p. 1) – and some commentators have identified a ‘spatial turn’ across the whole field of the humanities and the social sciences (Thrift, 2002).

(4) This turn has been sustained, in part, by a recognition that the outcome of processes differs from place to place. The variable character of the Earth’s surface has long driven enquiries into areal differentiation in both physical and human geography, and contrary to the predictions of prophets and critics of modernity, the transformations brought about by globalization have not planed away differences: instead, they have produced new distinctions and juxtapositions. Physical geography has always been acutely sensitive to macro- and meso-variations in landforms and processes, particularly those related to climate and geology. But we now have a clearer sense of the ways in which those variations have been culturally coded and constructed: W.M. Davis’ once canonical (1899a) description of fluvial erosion in temperate regions as the ‘normal’ cycle of erosion (which would startle people living in other regions), for example, and the vast discursive apparatus of tropicality that yoked land to life in low latitudes. Spurred on by the rapid rise of Earth Systems Science, we also have a much surer understanding of the global regimes and interdependencies in which environmental variations are enmeshed (Slaymaker and Spencer, 1998). In much the same way, human geography retains its interest in the particularity of place, but now usually works with a ‘global sense of place’ (Massey, 1994a; cf. Cresswell, 2004). Similarly, regions are now rarely seen as the independent building blocks of a global inventory; a revitalized regional geography focuses instead on the porosity of regions and on the intersecting processes through which their configurations are produced and transformed (Amin, 2004b). Here too, geography is not alone in its interest: area studies, international relations and international studies have declared interests in these issues too, though where these interests have been wired to the conduct of foreign policy they have typically provided a narrower, more instrumental framing of interdependence than is now usual in geography.

More fundamentally, however, the spatial turn has also been sustained through investigations of the ways in which space affects the very operation of processes. It is now widely recognized that processes are not indifferent to the circumstances and configurations in which they operate, and it is this ‘thrown-togetherness’ that has prompted a renewed interest in spatial ontology (Massey, 2005). This was, in a way, precisely Hartshorne’s point – and it is also the pivot around which...
so much of Torsten Hagerstrand’s extraordinary experiments with time-geography moved – but it is now being sharpened in radically different ways. It is also why geography has always placed such a premium on fieldwork (which was focal to Stoddart’s account too). Unlike field sciences, laboratory sciences can, in some measure, control for disturbances and isolate parameters to create idealized states. In much the same way, spatial science was an attempt to prise apart different spatial structures – the hexagonal lattices of central place systems, the wave forms of diffusion processes – and then search for commonalities within these spatializations (market areas and drainage basins as hexagons) or combine them in idealized models (the diffusion of innovations through central place systems). These were all attempts to order what is now most often seen as a partially ordered world – to tidy it up. As the philosopher A.N. Whitehead warned, however, ‘Nature doesn’t come as clean as you can think it’, and it is in this spirit that much of geography is increasingly exercised by the ways in which the coexistence of different spatializations perturbs, disrupts and transforms the fields through which social and biophysical processes operate. Physical geography was in the vanguard of attempts to find the terms for what B.A. Kennedy (1979) memorably described as ‘a naughty world’, and since then human geography has also recognized the non-linearity, contingency and complexity of life on Earth.

(5) The processes with which geography is concerned are conventionally and collectively identified as ‘social’ (economic, cultural, political etc.) and ‘biophysical’ (biological, chemical, geophysical etc.). These two realms have often been assigned to a separate human geography and physical geography, and the relations between the two have frequently prompted concern, on occasion even antagonism. In some institutional systems the two are more or less completely separate – in the Nordic countries, for example, there are usually separate university departments of human and physical geography – while in others one more or less dominates to the virtual exclusion of the other (in India, human geography is considerably more prominent than physical geography, for example, while in the USA, until very recently, ‘Geography’ was overwhelmingly human geography). Although most major geographical societies publish general journals that include papers in both physical and human geography – in the English-speaking world, these include the Annals of the Association of American Geographers, Canadian Geographer, Geographical Journal, Geographical Research, Geographical Review, South African Geographical Journal and the Transactions of the Institute of British Geographers – in recent years many of them have found it difficult to attract physical geographers to their pages. (In Sweden, the English-language Geografiska Annaler is published as separate series in physical and human geography.) There are some newer, general journals produced by commercial publishers too, notably Geoforum, Geoforum and Geography Compass, and also technical journals such as Geographical Analysis and the International Journal of Geographical Information Science. Publishing in the same journals does not imply a common discursive community, of course, and neither does it necessarily produce one: the sheer volume of academic publication makes most readers ever more selective (and perhaps idiosyncratic). But in any case the numbers of general journals have been dwarfed by the explosion of specialized, sub-disciplinary journals such as Earth Surface Processes and Landforms, The Journal of Biogeography, Physical Geography and Progress in Physical Geography on one side, and Antipode, Cultural Geographies, Economic Geography, the Environment and Planning journals, Gender, Place and Culture, Journal of Historical Geography, Political Geography, Progress in Human Geography and Social and Cultural Geographies on the other. Many of these journals advertise themselves as ‘interdisciplinary’, but the two groups reach out in opposite directions – to the atmospheric, biological and Earth sciences, or to the humanities and social sciences – rather than to each other.

Openness to other disciplines is widely accepted as indispensable for intellectual vitality, but there has also been a persistent anxiety that arrangements and practices such as these make a mockery of claims that geography studies the relations between the human and physical worlds, and at the limit threaten geography’s institutional survival when ecological awareness and demands for sustainable development are being articulated by other disciplines and emerging interdisciplinary fields (cf. Turner, 2002). To be sure, human geographers have long had important things to say about nature – it was only on the isotropic planes of spatial science that the biophysical environment was erased – and a host of studies in cultural ecology, environmental...
HISTORY, HAZARDS research and POLITICAL ECOLoGY testify to the power of their contributions. Similarly, physical geographers have long been interested in the intersection of human and physical systems (cf. Bennett and Chorley, 1978). In geomorphology, many consultative, geotechnical projects – perhaps most obviously on flooding, soil erosion, slope stability and the like – reveal the continuing vitality of this stream of work, and the atmospheric sciences have placed considerable emphasis on their practical relevance. In the future, a revitalized BIOGEOGRAPHY (as a sort of ‘living Earth science’) may well make some of the most direct connections to human geography and, indeed, to green politics, while pressing issues of global environmental change and GLOBAL WARMING require a transdisciplinary approach that speaks across the sciences, social sciences and humanities (see also Turner, Clark, Kates, Richards and Mathews, 1990).

But to have important things to say – and vital questions to address – does not mean that human and physical geographers speak the same language, and translation has its own problems (Bracken and Oughton, 2006). Many commentators, inside and outside geography, have insisted on a fundamental distinction between the methods of the natural sciences (that probe an ‘object-world’) and those of the humanities and social sciences (that probe a ‘subject-world’). Unlike pebbles rolling along the bed of a river or grains of sand cascading over the crest of a dune, human beings are suspended in webs of meaning: those meanings make a difference to conduct in ways that have no parallel in the domain of the natural sciences, and their elucidation requires radically different interpretative procedures. Proponents of HUMANISTIC GEOGRAPHY were among those most likely to advance these arguments in the 1970s and 1980s, but the rise of POSTMODERNISM and the correlative CULTURAL TURN across the humanities and social sciences in the 1990s – and in particular the so-called ‘science wars’ epitomized by the Sokal affair (in which physicist Alan Sokal successfully submitted a spoof ‘cultural studies’ article to the journal Social Text; cf. Ross, 1996) – must have convinced many physical geographers that their commitment to ‘Science’ put them at a considerable distance from many, if not most, human geographers.

There have been three major responses to such polarizing views. The first has been to appeal to science studies (see SCIENCE) to argue that physical geography, like ‘science’ more generally, is a social practice too; it has its own, highly formalized rules, but it constantly traffics in meanings and interpretations. Seen thus, physical geographers are caught in the HERMENEUTIC circle, and as invested in (serious) language games and qualitative modes of representation – and hence in textualization, RHETORIC and the like – as human geographers (Sugden, 1996; Spedding, 1997; Phillips, 1999, pp. 758–9; Harrison, 2001). These commonalities extend beyond the notebook or the printed page, however, and include, crucially, the performance of FIELDWORK (Powell, 2002). The second response has been to return to PHILOSOPHY and explore post-positivist philosophies of science that provide more nuanced explanations of both social and biophysical systems, and allow for a more sophisticated understanding of contingency than the objectivist canon. REALISM has played a pivotal role here, not least through its qualified NATURALISM, and following its early consideration by human geographers (Sayer, 1992 [1984]) it has been explored by a growing number of physical geographers (Richards, Brooks, Clifford, Harris and Lane, 1998; Raper and Livingstone, 2001). The third response, stimulated by attempts to theorize the PRODUCTION OF NATURE (Smith, 2008 [1984]), has been to call into question the very distinction between the ‘social’ and ‘biophysical’ (Braun and Castree 1998; Castree and Braun, 2001) and to recognize the vital importance of ‘hybrid geographies’ (Whatmore, 2002b). A host of new approaches has con founded the deceptively commonsensical partitions between ‘culture’ and ‘nature’, including ACTOR-NETWORK THEORY, AGENT-BASED MODELLING, COMPLEXITY THEORY and NON-REPRESENTATIONAL THEORY. With one or two exceptions, it seems that human geographers are more drawn to some of these possibilities and physical geographers to others, and they do not in themselves constitute a common intellectual language. But what C.P. Snow famously castigated as ‘the two cultures’ in the late 1950s, one literary-social and the other physical-scientific, has come to be recognized as an artifice, and there have been a number of attempts to conduct what the Royal Geographical Society/Institute of British Geographers called ‘conversations across the divide’ (Harrison, Massey, Richards, Magilligan, Thrift and Bender, 2004).

Not all observers of interventions like these are sanguine about the prospects for a plenary geography (cf. Johnston, 2005b; Viles, 2005),
and at the end of the day it may not matter very much. Most physical and human geographers are probably too involved in their own teaching and research to bother very much about such meta-issues. If they are interested in (say) residential segregation in cities or the dynamics of gravel-bed rivers, most scholars pursue whatever avenues of enquiry seem most promising, and do not draw back at disciplinary borders or worry about disciplinary integrity. It is hard to say – or see – why they should. To be sure, some work is by its very nature hybrid – hence the rise of various ‘environmental’ geographies – but it is a mistake to identify institutional politics with intellectual substance. Funding for teaching and research has become a crucial issue for all disciplines, and its impact should not be minimized. Advertising the capacity of geography to bring together the sciences, social sciences and humanities may bring its institutional rewards, but the intellectual realization of an interdisciplinary project through disciplinary privilege is surely a contradiction in terms. Disciplines are contingent institutional arrangements, and while each has a canon of sorts, activated through courses and textbooks, students and professors, societies and journals, and while there have often been attempts to police the frontiers (or to extend them through disciplinary imperialism), the fact remains that intellectual work of any significance has never been confined by administrative boundaries. Most scholars travel in interdisciplinary space, and while geography may have been unusually promiscuous in its encounters, it is by no means alone: as Gregson (2005, p. 7) astutely remarks, ‘ours is increasingly a post-disciplinary world in which the geographical is critical but not ours to possess’.

(6) The emphasis on process-based explanations is common to human geography, physical geography and many of the interchanges between them. Contemporary geographical enquiry does not stop at mapping outcomes – a sort of global gazetteer – and the friction of distance is no longer viewed as an adequate surrogate for the operation of the processes that produce those outcomes. Hence the focus on practices and structures, micro-processes and systems. In human geography, the argument was put with characteristic force by Soja (1989, pp. 37–8), who identified a persistent disciplinary tendency to limit enquiry to the description and calibration of ‘outcomes deriving from processes whose deeper theorization was left to others’ in ‘an infinite regression of geographies upon geographies’. His solution, like those of an increasing number of his peers, was not to import theorizations of processes from social theory, but (much more radically) to ‘spatialize’ social theory ab initio and to think about the production of space in ways that eventually troubled the dualism (even the dialectic) of spatial form and social process. Others followed other routes to different destinations, but the common result was to underline the importance of ontology to human geography. Some physical geographers had started to focus on process-based explanations in the 1950s, under the influence of American geologist and geomorphologist Arthur N. Strahler (1918–2002) and his graduate students, and by the time human geographers were recoiling from spatial fetishism, their physical colleagues were heavily invested in the measurement of atmospheric, biological and geomorphological processes. But here too there has been a concerted attempt to think about process in less mechanistic terms than those early projects allowed, and in consequence to recognize the practical importance of ‘philosophical speculation about the fundamental “stuff” or substance of reality’ for geomorphology and other fields of physical geography (Rhoads, 2006, p. 15; cf. Harvey, 1996).

This interest in process is, in one sense, a peculiarly modern fascination: in a world where, as Marx so famously put it, ‘all that is solid melts into air’, there is a particular premium on describing, monitoring and accounting for change. But there is also a vital interest in planning, predicting and implementing change. This has had two crucial impacts on the development of contemporary geography. The first is a renewed interest in political and ethical questions. Intervening in situations of politico-ecological catastrophe or war, where environmental justice, human rights and even our very survival as a species may be at stake, requires more than a detached, analytical gaze. In its classical, Greek form, geography was closely associated with political and moral philosophy, and the luminous writings of the gentle anarchist geographer Pyotr Kropotkin (1842–1921) provided a rare, modern insistence on the importance of such questions. These were revived most effectively by David Harvey in the second half of the twentieth century, whose forensic dissection of late capitalism through a close reading and reformulation of Marx’s writings did much to alert human geographers to the ineluctable politics of their enquiries. This raised
a series of questions about EPistemology and the limits of geographical knowledge that required a critique not only of geography’s technical and conceptual armatures – including those derived from its newfound interest in MARxISM – but of (for example) the MASCULINism that was reproduced through its concepts and practices (Rose, 1993). The ongoing formation of a CRITICAL HUMAN GEOGRAPHy, including CRITICAL GEOPOLITICS and FEMINIST GEOGRAPHIES, reinforced and generalized these concerns (see also RADICAL GEOGRAPHy). Physical geographers were by no means indifferent to them, but they seem to have been more directly moved by the consideration of an explicitly environmental ETHICS. Indeed, moral philosophies more generally have assumed such prominence alongside philosophies of science in contemporary geographical enquiry that some observers have discerned a ‘moral turn’ across the discipline as a whole (Barnett and Land, 2007; cf. Smith, 2000a; Lee and Smith, 2004).

The second consequence of orienting geographical enquiry towards change and the future has been a recognition that geography’s responsibilities extend beyond a critical involvement in public policy – important though that is – to a considered engagement in public debate (Murphy, 2006). This involves a more rigorous reflexivity: not only a careful and constructive critique of theories, methods and materials, but also an examination of the circumstances in which geographies are being produced and circulated and of the consequences in which they are implicated. This process might well begin ‘at home’, in the classroom and the lecture theatre, but it cannot end there. The late-modern corporate university, with its audit culture, its vested interest in the commodification of knowledge, and its incorporation of many of the modalities of neo-liberalism, materially affects teaching and research. At the same time, however, precisely because geographical knowledges are produced at so many sites outside formal educational institutions, public responsibility also involves a willingness to learn from and engage with audiences far beyond the academy, many of whose lives have been ravaged by the unregulated intrusions of the supposedly ‘free’ market, by new rounds of accumulation by dispossession and by the forcible installation of radically new geographies (Harvey, 2003b; Lawson, 2007). To analyse and challenge these impositions requires more than ‘earth-writing’ in its literal sense; geographers neglect the art of writing at their peril, but they also need to write in different (‘non-academic’) styles for different audiences, to explore new technologies and media, and to experiment with different modes of presentation. None of this is about experimentation for its own sake, because the new-found interest in public geographies is not only about producing counter-publics imbued with a critical geographical imagination: it is also, crucially, about learning from and engaging them in open and respectful dialogue. This matters because geography is not, as the old saw has it, ‘what geographers do’: it is, in an important sense, what we all do. Claims about ‘the end of geography’ have been made since at least the early twentieth century, but (then as now) they have also always been claims about the rise of new geographies and, less obviously perhaps, the grids of power that they forward (Smith, N., 2003c). ‘Geo-graphing’, whether ‘professional’ or ‘popular’, thus never works on a blank surface: it always involves writing over (superimposition) and writing out (erasure and exclusion: Sparke, 2005, p. xvi). Textbooks and dictionary entries are no exception. DG

**geography, history of** The term ‘geography’ defies simple definition. The standard, non-specialist dictionary characterization of it as ‘The science which has for its object the description of the Earth’s surface’ fails to capture the complexity of geography’s history: the disorderliness of the past, to put it another way, resists essentialist specification. As an enterprise – whether scholarly or popular, whether in terms of disciplinary history, discursive engagements or practical operations – geography has meant different things at different times and places. In fact, geographical knowledge and practice been intimately intertwined with a host of enterprises: natural magic, imperial politics, celestial cartography, natural theology, conjectural prehistory, mathematical astronomy, speculative anthropology, travel-writing, national identity and various species of literary endeavour. It is therefore understandable that there is no unchallenged consensus on what it means to write geography’s history. And although the task of reconstructing geography’s history has had its critics, some of whom are suspicious of the entire enterprise (Barnett, 1995), it would
not be unreasonable to suggest that some of the most significant interventions into recent debates on the relationships between knowledge, REPRESENTATION and POWER have emanated from those concerned with the ways in which geographical knowledge is constituted socially, historically and spatially.

As a professional discipline, geography’s GENEALOGY is part and parcel of the story of the division of intellectual labour that delivered modern ‘disciplines’ around the end of the nineteenth century. It has been claimed that before this period, in particular during the period of the European ENLIGHTENMENT, the label ‘geography’, as the precursor of the modern discipline, had fairly specific connotations that distinguished it from other fields of endeavour through its focus on the determination of relative location and description of ‘phenomena to be found in those locations’ (Mayhew, 2001, p. 388). But it has been shown that boundaries around the subject were never quite so sharply delineated and that geography took various shapes in different texts, at different sites and in different practical pursuits (Withers, 2006). However that particular terminological debate is to be resolved, histories of geography as a DISCOURSE continue to be written without the definitional constraints that recent history and contingent institutional arrangements necessarily impose on the modern-day discipline. To be sure, the histories of geography as discourse and discipline are interrelated in intimate ways, and there is good evidence to suppose that recent practitioners of these enterprises deploy similar historiographical tactics, though there do remain differences of substance and style in the conduct of these two enterprises. The increasing acknowledgement too that geographical pursuits in the public sphere – popular geographies – are in need of further scrutiny parallels, in some respects, the surge of interest in social studies of popular science.

So far as the modern discipline of geography is concerned, then, those chronicling the course of historical change have conducted their investigations in a variety of ways. A range of different strategies has been pursued. First: institutional history. Those dwelling on the history of geography’s institutions have concentrated on the subject’s organizational expression, and accordingly have produced narratives of a range of GEOGRAPHICAL SOCIETIES, or have enquired into the evolution of geography in different national traditions. Such projects have tended to concentrate on geography’s modern narrative, but even in its pre-professional guise, the subject’s institutional manifestation was significant. Its presence in university curricula, for example, has been traced back to the period of the SCIENTIFIC REVOLUTION, when it was taught in conjunction with practices such as astronomy and practical mathematics (Withers and Mayhew, 2002; Livingstone 2003c). Yet there remains significant work to be done. For the English-speaking world, to take a single example, the dimensions of the Royal Geographical Society’s influence on the mutual shaping of geographical knowledge and Victorian society still remain to be charted. In other national and provincial settings, similar questions are in need of resolution.

Second: biography. The life stories of a number of key professional geographers, including Halford Mackinder, Ellsworth Huntington, Mark Jefferson, William Morris Davis and Elisée Reclus, have been narrated. Some (though not all) of these accounts have been frankly disappointing in their lacklustre narrative line and an absence of historiographical sophistication, though N. Smith’s (2003) more recent analysis of Isaiah Bowman displays a richness and depth to which other accounts could profitably aspire. Alongside these full-length studies, a suite of shorter biographical sketches of a wider range of figures continues in the serial Geographers: Biobibliographical Studies. Biographical treatments are also available of figures looming large in the history of the subject’s pre-professional past, including more recently studies of Alexander von Humboldt (Rupke, 2005), George Perkins Marsh (Lowenthal, 2000) and Nathaniel Shaler (Livingstone, 1987b). New energy has also been injected into the biographical impulse by the pursuit of what might be called ‘life geographies’ or ‘life spaces’ – namely, by taking with much greater seriousness the sites and spaces through which human beings transact their lives (Daniels and Nash, 2004). Recent autobiographical experiments by geographers have also added to this perspective; these raise significant questions about the relative value of autobiography and biography, the difference between a ‘life as it is lived’ and ‘a life as it is told’, and the inescapable HERMENEUTIC complications involved in fusing present horizons with those of the past.

Third: histories of ideas. Alongside institutional history and biographical narrative, a number of works dwelling on the history of geographical ideas within academic geography have appeared. Some are specialist treatments of how modern geographical thought has
engaged with wider theoretical currents (Peet, 1998); some rehearse the internal history of sub-disciplines (for historical geography, for instance, see Butlin, 1993); others have centred on school geography texts and their role in conveying imperial attitudes about race and gender (Maddrell, 1998). Cumulatively, works such as these demonstrate the diverse range of interests and styles employed to interrogate geography’s academic history.

Contributions dealing with geographical discourses also come in a variety of guises and encompass a wide spectrum of topics. Beazley’s (1897–1906) *The dawn of modern geography* emphasized the history of medieval travel and exploration; Eva Taylor’s (1930) portrayal of Tudor geography centred on mathematical practice, surveying and navigation; and J.K. Wright’s (1965 [1925]) account of the Geographical lore of the time of the Crusades rehearsed place description, cartographic ventures and cosmographical convictions in a project that self-confessedly covered ‘a wider field than most definitions of geography’ (p. 2). Newer ways of thinking about medieval geography have also recently surfaced, notably the researches of Lozovsky (2000), who explores medieval scholars’ perceptions and representations of geographical space and its transmission. Glacken’s (1967) monumental *Traces on the Rhodian shore* mapped the contact zone between nature and culture, and openly acknowledged that he transcended the conventional limits of the modern discipline. Bowen’s (1981) compendious survey of geographical thought from Bacon to Humboldt constitutes a sophisticated historical apologia for an ecological, anti-positivistic vision of the subject. Alongside these treatments of geographical discourse is a range of related contributions dealing with allied subjects such as biogeography (Browne, 1983), meteorology (Anderson, 2005a), Earth and environmental science (Bowler, 1992; Rudwick 2005), cartography (Edney, 1997; Burnett, 2000), oceanography (Rozwadowski, 2005) geomorphology (Davies, 1969; Kennedy, 2005), human ecology (Mitman, 1992) and ideas of nature (Coates, 1998). In many cases, these undertakings have deepened connections between geographers and historians of science, and opened up new and fertile lines of enquiry. If these works are indicative of geography’s long-standing location within the scientific tradition, there is equally abundant evidence for the subject’s textual heritage that connects it with the humanities. Since the period of the scientific revolution, geography has also been concerned with matters of commerce and strategy, and also with regional descriptions (Cormack, 1997). This realization has led Mayhew (2000) to argue that early modern geography was deeply implicated in debates about political theology and cultural identity during the so-called long eighteenth century. The subject’s intimate connections with historical scholarship, moral philosophy, speculative anthropology and various species of literary endeavour, alongside its association with natural philosophy, have thus been emphasized. One mark of this connection is the way in which geographical works depicted denominational spaces, the Dissolution of the Monasteries and political insurrection at the time of the English Civil War; thereby, the inescapably political character of regional description and geographical compilation is disclosed. Another indication is the extent to which writers such as Samuel Johnston and Shakespeare’s commentators were concerned with matters of geographical sensibility (Roberts, 1991).

These relatively specialist studies are supplemented by a number of what Aay (1981) calls ‘textbook chronicles’ – synthetic treatments designed for student consumption that provide an overview of the field. It is now plain, however, that these surveys have all too frequently lapsed into apologetics for some particular viewpoint – geography as regional interrogation, the study of occupied space or some such. Moreover, their strategy was typically presentist, namely using history to adjudicate on present-day controversies (though the inescapability of certain dimensions of the present as indicated above need to be registered); internalist, in the sense that they paid scant attention to the broader social and intellectual contexts within which geographical knowledges were produced; and cumulative, portraying history in terms of progress towards some perceived contemporary orthodoxy. Scepticism about precisely these assumptions has fostered greater sensitivity to currents of historiographical thinking, and a range of strategies have therefore been deployed in the endeavour to deepen analyses of geography’s genealogy.

Leaving aside their problematic reading of Kuhn, some have turned to his *Structure of scientific revolutions* (1970 [1962]) to characterize the history of geography as an overlapping succession of paradigms enshrined in a number of key texts: Paul Vidal de la Blache’s possibilism, Ellsworth Huntington’s environmental determinism, Carl Ortwin Sauer’s
LANDSCAPE MORPHOLOGY, Richard Hartshorne’s AREAL DIFFERENTIATION and Fred K. Schaefer’s EXCEPTIONALISM are typical candidates for paradigm status (see SCIENTIFIC REVOLUTION(S)). In such scenarios, however, a good deal of historical typecasting and editorial management has had to be engaged in. Others have taken more seriously the role of ‘invisible colleges’ and ‘socio-scientific NETWORKS’ (Lochhead, 1981). At the same time, perspectives from HISTORICAL MATERIALISM have been marshalled as a means of elucidating the way in which geographical knowledge and practices have been used to legitimate the social conditions that produced that knowledge in the first place (Harvey, 1984). Still others have seen in the philosophical literature on the cognitive power of METAPHOR a key to unlocking aspects of geography’s history (Buttimer, 1982), through delineating the different uses of, say, mechanistic, organic, structural and textual analogies. The insights of Foucault on the intimate connections between SPACE, SURVEILLANCE, POWER and knowledge, and of Said on the Western construction of ‘non-Western’ realms (see ORIENTALISM) have also opened up new vistas to the history of geography by unmasking the pretended neutrality of spatial discourse in a variety of arenas both within and beyond the academy. The related need to open up conventional histories of geography to non-Western traditions is a real desideratum.

More recently, rapprochement with SCIENCE STUDIES has opened up new lines of enquiry in which the social constitution of knowledge and an empirical examination of actual knowledge-making practices have come to the fore. Barnes (1996, 1998), for example, has drawn on the methodology of social studies of scientific knowledge in his account of the history and conceptual structure of modern ECONOMIC GEOGRAPHY in general, and geography’s QUANTITATIVE REVOLUTION in particular. Other applications of this general perspective within human geography are advertised in this Dictionary’s entry on SCIENCE (including SCIENCE STUDIES). Among these are the ACTOR-NETWORK theory of Bruno Latour, the so-called Edinburgh strong programme in the sociology of knowledge, a range of feminist epistemologies, the ethnographic methodologies of the micro-anthropology of science and various other constructivist perspectives. All of these combine to situate cognitive claims in the conditions of their making, and to render problematic distinctions between internal and external history of scientific knowledge.

Cumulatively, such calls for re-reading geography’s history have contributed to a wide range of revisionist accounts of particular episodes, among which mention might be made of the links between magic, mysticism and geography at various times (Livingstone, 1988; Matless, 1991), geography’s complicity in the shaping of imperial ambitions and national identity in the early modern period (Withers, 2001: see IMPERIALISM), the intimate connections between geography, EMPIRE, HEALTH and racial theory (Livingstone, 1991; Bell, 1993; Godlewska and Smith, 1994; Driver, 2001a), the relations between LANDSCAPE REPRESENTATION, artistic convention and denominational discourse (Cosgrove and Daniels, 1988; Mayhew, 1996), the circumstances surrounding debates over the boundary between geography and sociology in turn-of-the-century France (Friedman, 1996), the imperial mould in which early ENVIRONMENTALISM was cast (Grove, 1995), the relations between geography and TRAVEL-WRITING, and calls for feminist readings of the tradition (Domosh, 1991, Rose, 1995). There is a growing recognition too that the narrative of Western geography cannot be sequestered from its wider channels of intellectual exchange even in the early modern period. Patterns of TRADE and the transmission of knowledge between ‘East’ and ‘West’ played a major role in the shaping of various European geographies. As for practical engagements, Ryan’s (1998) account of the connections between geography, photography and racial representation in the Victorian era, and feminist reflections on FIELDWORK have opened up these arenas to theoretically informed interrogation. Embedded within at least of some of these accounts is a conviction that ‘geography’ is a negotiated entity, and that a central task of its historians is to ascertain how and why certain practices and procedures come to be accounted authoritative, and hence normative, at certain moments in time and in certain spatial settings.

It is plain, then, that the ‘history of geography’ comprises a variety of enterprises that have been engaged in various ways. Nevertheless, a broad shift can be detected from the ‘encyclopaedism’ of earlier works (which operated in a cumulative-chronological fashion) towards a more recent ‘genealogical’ perspective (which aims to disclose the tangled connections between power and knowledge). The subversive character of the latter has been embraced with differing degrees of enthusiasm: some now insist that the idea of history as a single master narrative is a Western
‘myth’, while others, unenamoured of an altogether radical relativism (in which truth is taken to be relative to circumstance) or suspicious that the genealogist is implicated in an impossible self-referential dilemma (namely, that the thesis is self-refuting), suggest that there is more value in thinking of discourses as ‘contested traditions’ – socially embodied and temporally extended conversations that act as stabilizing constraints on the elucidation of meaning (MacIntyre, 1990). Insofar as ‘encyclopaedia’, ‘genealogy’ and ‘tradition’ as modes of historical interrogation reflect differing attitudes towards what has come to be called the Enlightenment project, the history of geography – as a scholarly pursuit – has a significant role to play in debates within the discipline over the relations between knowledge, power, representation and social construction (Gregory, 1994).

Moreover, recent reassertions of the significance of place and space in historical investigations of human knowing (Shapin, 1998; Livingstone, 2003c) are bringing the issue of geography’s own knowledge spaces to the fore. Thus attention is beginning to be directed towards understanding the different sites and spaces – at a range of scales – within which geographical knowledge is produced and circulates. Investigations of the performativity of geographies in seventeenth-century court masques and triumphal processions (Withers, 1997), field sites and expeditionary settings as venues of geographical enquiry and evocation (Driver and Martins, 2005), museums as spaces of display (Naylor, 2002), archives and the construction of geographical knowledge (Withers, 2002), the use of personal diaries and field journals to reconstruct learning experiences (Lorimer, 2003), mission stations as imperial sites of local knowledge (Livingstone, 2005b), ships as instruments of geodetic survey (Sorrenson, 1996), and meteorological stations (Naylor, 2006) are illustrative of this spatial turn. The city itself – as a laboratory field-site – has also been investigated as an epistemic ‘truth-spot’ and thus fundamental to the credibility of certain scientific claims; this is exemplified par excellence in the Chicago School of urban studies (Gieryn, 2006). Other venues such as census bureaus, GIS laboratories, botanical gardens, trading floors, art studios, fields of military operation (see war) and government departments – where geographical knowledge of various sorts is made and remade – are no less in need of interrogation. Interest too is developing on the ways in which geographical texts have been read in particular locations, and of regional differences in what has been called reviewing cultures (Rupke, 1999). All this confirms that ‘the history of geography’ as an undertaking is now beginning (all too ironically) to take ‘geography’ much more seriously – namely, by reconceptualizing the enterprise as ‘the historical geography of geographical knowledges and practices’.

geo-informatics Geo-informatics is the interface and collaboration between the Earth and the information sciences (notably computer science) to use geocoded data (see geocoding) to better model, visualize and understand the Earth’s complexity. More specific topics of research that have been included at the annual international conference in geo-informatics have included: discovery, integration, management and visualization of geoscience data; internet-enabled geographic information systems (GIS); location-based services, including global positioning systems; spatial data modelling in hyperspaces; remote sensing; and interoperability.

Looking at the research themes listed above, it is evident that the interests of geo-informatics overlap with those of geographic information science and geocomputation. To find common ground is not surprising: each has an interdisciplinary nature, bound by an interest in geographical datasets and the computational requirements to store, process and make sense of them. Each also brings a spatial perspective to answer the questions of social and physical science (and also the interactions between social and physical systems). And each is a young field of research, born out of much older traditions. However, whereas the origins of GISc are in navigation, cartography, demography, resource management and spatial analysis, and the roots of geocomputation lie in using high-performance computing for applied spatial science, the seeds of geo-informatics were germinated in the geodetic (e.g. surveying) traditions of engineering, geology, oceanography and other geosciences.

These geodetic and geoscientific foundations are revealed by the keen focus of geo-informatics on geographical data – their
storage, integration, analysis and visualization. Traditional surveying in the geosciences has involved a methodological and spatially ordered collection of data or samples of a phenomenon, in order to better understand that which is being investigated. The need for scientific rigour has not changed in research. What is new is the more extensive surveillance of the Earth’s social and natural systems (e.g. by remote sensing) that has developed over recent decades, and the huge amounts of data that routinely are collected by (or to enable) the functioning of societies (e.g. population data from governance, consumer data from commerce, organizational data from pubic service management and so forth).

Increased data sharing, new technologies and new techniques for analysis affect the theory and practice of handling geographical information (Goodchild and Longley, 2005). For example, storing extensive and multivariate datasets to model and represent complex systems (physical or social) is not best achieved by the sorts of simplifying assumptions commonly used to capture and to map socioeconomic data. A straightforward database design used in GIS takes the idea that geographical features have a fixed and unambiguous location which can be defined by their coordinate position in a planar space, the encoding of which is prioritized. Other information, such as the height of the Earth’s surface at the feature’s position, the height of the feature itself or the data/time at which the feature was observed are secondary information, stored as ‘just another’ attribute alongside other information about the feature (e.g. what the feature is called, its size etc.) (Worboys, 2005). Such an approach works well when mapping, for example, census information collected on a particular date, once every ten years, and describing geographical features that are fixed in time and space (i.e. the census population, per census tract, on the date of enumeration). It is not suitable for storing or visualizing data about dynamic processes where the temporal component of the analysis is at least as important as the spatial, or for modelling or querying genuinely threedimensional features – for example, rock or soil layers, or subterranean walkways (at subway stations) that can fold under themselves and therefore occupy multiple positions in multidimensional space (Raper, 2000).

To integrate and to extract meaningful knowledge from data collected for different reasons, at different times, at different scales, using different classification frameworks and different ontologies, is a task that bridges between science and computers and that provides the structure of geo-informatics research. It is not an easy task. As the geo-informatics portal at the Pan-American Center for Earth and Environmental Studies states, ‘currently, the chaotic distribution of available data sets, lack of documentation about them, and lack of easy-to-use access tools and computer modeling and analysis codes are major obstacles for scientists and educators alike’ (http://paces.geo.ute.edu). There, geo-informatics is described as the ‘field in which geoscientists and computer scientists are working together to provide the means to address a variety of complex scientific questions using advanced information technologies and integrated analysis’.

Writing from an urban and regional planning perspective, Holmberg (1994) sums up the scope of geo-informatics which incorporates elements of computation, science, systems modelling and society. To him, geo-informatics is the technological and scientific discipline guiding the design of systems for sensing, modelling, representing, visualizing, monitoring, processing and communicating geo-information. The ‘big challenge’ of geo-informatics, then, is to handle geographical information in geographically minded ways, to help understand geographical systems, to undertake geographical problem solving and to progress the development of the geographical sciences.

geoipety A term coined by J.K. Wright (1947) to refer to a reverential attitude towards and caring for the Earth. After three decades of relative obscurity, the term was re-introduced to a new generation of geographers in the mid-1970s by Yi-Fu Tuan (1976a). It formed an important component of Tuan’s notion of tophilia, which in turn was one of the key concepts in humanistic geography. The implied spiritual approach to nature, while rooted in nineteenth-century romanticism, continues to resonate for contemporary romanticists, including the exponents of deep ecology.

geopolitics A title of an academic journal, a catch-all category for international violence,
an orphaned sub-field of late imperial geography resurrected in neo-imperial America and, simultaneously, the focus of diverse forms of demythologization and debunking by scholars of critical human geography, this is a term that defies easy definition. As a category of news reporting, it is used in the media to describe violence relating to the division, control and contestation of territory. The business pages of newspapers thus often feature references to ‘geopolitical concerns’ as a way of describing the impact of international politics and violence. After terrorist attacks on commuter trains in India and Israel’s invasion of Lebanon in the summer of 2006, for instance, The Financial Times review of global markets read as follows: ‘Gold also pushed higher on continued geopolitical concerns following bomb blasts in Mumbai and clashes around the Israel–Lebanon border’ (Tassell, 2006, p. 26). Academically, however, geopolitics is a much more complex and contested term, with a long history of formal definition and redefinition.

The original definitions of the field go back to the ‘classical geopolitics’ of military-minded academics such as the British imperialist Halford Mackinder, the Nazi expansionist Karl Haushofer and the Dutch-American Cold War strategist Nicholas Spykman. For them, geopolitics was all about how international relations relate to the spatial layout of oceans, continents, natural resources, military organization, political systems and perceived territorial threats and opportunities (for an excellent overview, see Foster, 2006). In this respect, a constant geopolitical focus has been the Eurasian continental meta-region stretching from Eastern Europe through Russia to Central Asia. This was the so-called ‘Heartland’ that Mackinder argued was key to global imperial power (see IMPERIALISM). It was some of this same territory that Haushofer argued the Nazis should seize as LEBENSRAUM, or living-space, for their self-described master race. After the Soviet Union established control over the region at the end of the Second World War, it was this same area that Americans such as George Kennan argued should be contained, an argument that underpinned US COLD WAR geopolitics aimed at controlling what Spykman had previously described as the ‘Rimlands’ around the ‘Heartland’ (Dalby, 1990). Isaiah Bowman, the US geographer and presidential advisor who, early on, advocated American dominance in and around the region, was once dubbed ‘the American Haushofer’ (Smith, N., 2003c). However, just as American imperialists have traditionally talked about an American Century rather than a geographically defined AMERICAN EMPIRE, American advocates of geopolitical dominance have generally avoided talk of geopolitics because of its associations with European IMPERIALISM and FASCISM. This reticence amongst US strategists began to change after 11 September 2001: a shift towards unabashed imperial attitudes occurred that was also signalled by the return to influence of the old Cold War geopolitical grandee Henry Kissinger. But whether referring explicitly to geopolitics or not, geopolitical discourse has continued to develop apace since the end of the Cold War; the transition from President Reagan’s anti-Soviet invocation of an ‘Evil Empire’ to President Bush’s angst about an ‘Axis of Evil’ being just one of the more imaginative and egregious attempts to remap the terrain of Mackinder’s Heartland as a way of simultaneously defining the American HOMELAND (Coleman, 2004).

While classical geopolitics continues to inform policy-making, critical geographers have over the past two decades developed a vibrant new field of critical geopolitics. Under this broad umbrella they have sought to examine the ways in which a broad range of imaginative geographies, such as the ‘Evil Empire’, actively shape world politics (see O’ Tuathail, 1996b; O’ Tuathail and Dalby, 1998; Agnew, 2003a). Critical geopolitics continues to grow more diverse by the year: ranging from examinations of geopolitical discourse in the history of popular culture (Sharp, 2000a), to studies of the ORIENTALISM that informs the geopolitics of both the colonial past and present (Gregory, 2004; Slater, 2004), to critiques of the geopolitical justification of torture (Hannah, 2006b), to reflections on the geopolitical preoccupations of revolutionary Islam (Watts, 2007). Thus while practitioners of classical geopolitics keep producing geopolitical representations that they claim are real, the core concern for the critics is precisely this objectivist claim on reality. Critical geopolitics instead demonstrates the ideological power of geopolitical representations to ‘script’ space – to concoct, for example, a story about Iraq having weapons of mass destruction and then using that script to legitimate war. However, in debunking such geopolitical scriptings, the critical scholarship raises at least three further sorts of question about the relationships between geopolitics and the real world: the first concerns the relationship between imaginative geopolitical
scripts and the far from imaginative death and destruction they inspire or help legitimate; the second relates to how such destructive consequences relate to the CREATIVE DESTRUCTION of GLOBALIZATION and NEO-LIBERALISM; and the third concerns the reciprocal influence of these economic mediations on the ongoing articulation of new neo-liberal geopolitical scripts that emphasize ECONOMIC INTEGRATION over Cold War containment.

Geographical scholarship on the ‘war on terror’ has connected critical geopolitical concerns about the US President Bush administration’s fear-mongering with all three questions about the ties between geopolitics and real world relations. Derek Gregory (2004b) has shown how in Afghanistan and Iraq the people construed by the ‘war on terror’ script as the enemy have suffered lethal consequences as a result of the ‘god-tricks’ of long-distance geopolitical representations. He also has continued to argue in this way that the geopolitics has constructed spaces of exception (see EXCEPTION, SPACES OF) and legal vanishing points, where huge numbers of people are treated as outcasts from humanity and the tenuous protections of international LAW (Gregory, 2007). Focusing, by contrast, on the arrogance of the American exceptionalism that has helped create these spaces of exception, recent reflections on the ties between American imperialism and neo-liberalism have highlighted how the relationship is also highly contradictory. For example, geopolitical strategies about building American dominance over the MIDDLE EAST and its OIL spigots exist in uneasy tension with ongoing interests in maintaining transnational business, CLASS harmony and support for the dollar against the backdrop of rising concerns about American indebtedness to East Asian and OPEC owners of US bonds (Smith, N., 2003c; Harvey, 2004b). These economic contexts in which geopolitical scripts are developed and implemented have further been found to be changing the nature of the scripts themselves, leading to a neo-liberal geopolitics (Roberts, Secord and Sparke, 2003) which, with its distinctly economic emphases on globalization and connection over isolation and containment, has also been called ‘geo-economics’ (Sparke, 2005).

Geopolitik A school of POLITICAL GEOGRAPHY, and specifically GEOPLATICS, disseminated in inter-war Germany by the geographer and military officer Karl Haushofer (1869–1946) and the journal Zeitschrift für Geopolitik (1922–44). The term in fact originated with the Swedish political scientist Rudolf Kjellen, whose ideas, along with Ratzel’s organic theory of the STATE, provided a spurious rationale to justify German expansionism (Parker, 1985: see also ANTHROPOGEOGRAPHY; LEBENSRÄUM). Although Geopolitik was associated with Hitler’s Nazi Party, however, there were important differences. Whereas Geopolitik was influenced by the significance of natural laws in its understanding of social and political life (cf. DARWINISM), National Socialism saw societies as determined by biological inheritance and was both predicated on and powered by RACISM (Bassin, 1987a: see also FASCISM). The term is often used to portray Geopolitik as a purely German phenomenon, but it should be noted that the British geographer Sir Halford Mackinder also made reference to organic or natural understandings of state and society.

geostrategic realms The largest-scale division of the GLOBE in Cohen’s (2003) geopolitics of the world system. Large enough to be of global significance, geostrategic realms serve the interests of the powers that dominate them. Held together by trading, cultural and military connections, they change as economic and military forces evolve. Reflecting long-standing concerns with land and sea POWER in GEOPOLITICAL thinking, three geostrategic realms have been identified: the Atlantic and Pacific trade-dependent Maritime realm; the Eurasian Continental Russian Heartland realm; and the mixed Continental Maritime East Asia realm. The intellectual or practical significance of Cohen’s typology is far from straightforward, but the US military has developed its own geostrategic division of the world, the practical significance of which is only too clear (see Morrisey, 2008b). Different ‘unified combatant commands’ are assigned to different world regions:

US Africa Command (all of Africa except Egypt);
US Central Command (MIDDLE EAST and Central Asia);
US European Command (centred on Europe, including Russia);
US Pacific Command (including Australia, and South and South East Asia)
US Northern Command (North Africa)
gerrymandering The deliberate drawing of electoral district boundaries to produce an electoral advantage for an interested party. The term was coined by enemies of Massachusetts Republican Governor Elbridge Gerry, who created a district in 1812 that his party would win: it was shaped like a salamander – hence the neologism and the widespread (if false) belief that gerrymandering necessarily involves odd-shaped district boundaries. Although gerrymandering has long been practiced in the USA, it has only recently – and in specific conditions – been interpreted by the courts there as a constitutional violation (cf. DISTRICTING ALGORITHM; ELECTORAL GEOGRAPHY; REDISTRICTING).

ghetto An extreme form of residential concentration: a cultural, religious or ethnic group is ghettoized when (a) a high proportion of the group lives in a single area, and (b) when the group accounts for most of the population in that area. Although the practice of ghettoization – forcing a group to live separately within a city – originated in the urban quarters of pre-classical cities, the first use of the term occurred in late medieval Venice, where city authorities required Jews to live on a separate island (called ghetto), which was sealed behind walls and gates each night (Calimani, 1987). SOCIAL EXCLUSION was imposed by the dominant culture and, as such, reflected and reinforced the marginalization of the Jewish minority. However, while the ghetto was overcrowded and prone to fire and disease, Jews also gained some benefit from their enforced isolation, especially the right to practice their RELIGION and legal system and, perhaps, a degree of protection from more drastic forms of persecution (Wirth, 1928).

Instances of complete ghettoization have been rare (two modern exceptions are the Warsaw Ghetto, established as a way-station to the Nazi HOLOCAUST and designated areas for Black residential settlement in South African cities during the Apartheid regime). Early in the twentieth century, the term came to be used indiscriminately for almost any residential area identified with a particular group, even when it did not form a majority, and even when SEGREGATION was not the result of discrimination. This ambiguity was especially prevalent in the influential work of the Chicago sociologists (see CHICAGO SCHOOL), who even referred to a wealthy NEIGHBOURHOOD in the city as the ‘gilded ghetto’.

Researchers began in the 1970s to call for more analytical precision. Philpott (1991 [1979]), for example, distinguished between ‘slums’, areas of poverty where residents (frequently immigrants) leave as they acquire the means to do so, and ghettos, areas where residents are trapped in permanent poverty (also see Ward, 1989). Also, ghettos should not be confused with ethnic ENCLAVES, areas dominated by a single cultural group. Ghettos emerge when political and/or other institutions, such as the HOUSING MARKET, operate to restrict the residential choices of certain groups, channelling them to the most undesirable neighbourhoods (Thabit, 2003). They are the product of RACIALIZATION (see also ETHNICITY; RACE), where particular minority groups are judged by the majority to be genetically and socially inferior (Wacquant, 2001). There is always a degree of involuntary behaviour in the formation of ghettos, whereas ethnic enclaves arise when members of a group choose to live in close proximity (Boal, 1976; Peach, 1996ab).

The situation of African-Americans in the USA is typically seen as the defining example of contemporary ghettoization (see Darden, 1995; Wacquant, 2001). In the 1960s, some American social scientists began to assert that ghetto environments are so debilitating that a ‘culture of poverty’, associated with high CRIME rates, substance abuse, broken families and a reliance on social services, is transmitted from parents to children (cf. CYCLE OF POVERTY). These alarming views were instrumental in the ‘war on poverty’ declared by the US government, and were important ingredients in the inauguration of urban redevelopment programmes, increased social spending, educational reform, and heightened policing and surveillance of the INNER CITY (cf. URBAN RENEWAL). These initiatives were largely withdrawn in the conservative 1980s, but the argument that ghettos should be the focus of PUBLIC POLICY was revived later in the decade, as part of the UNDERCLASS debate. Again, proponents of this thesis believe that ghettos are not just places of grinding poverty, but also places where poverty is institutionalized (Wilson, 1987). Racialization and stigmatization combine to sharply circumscribe the opportunities available to residents of ghettos, so CHILDREN are locked into the same circumstances as their parents, if not worse. Similar arguments have surfaced in the UK (e.g. Rex,
Global cities/world cities

Major nodes in the organization of the global economy: hubs of economic control, production and trade, of information circulation and cultural transmission, and of political power. They are often represented in a hierarchically ordered network formation that spans the globe (for several representations, see Taylor, 2004). Peter Hall has credited Scottish urbanist Patrick Geddes (1854–1932; see Geddes, 1915) with introducing the term – although German literary giant Johann Wolfgang Goethe employed it as far back as the early nineteenth century, in reference to Paris. In Hall’s groundbreaking book *The world cities* ([1984] 1966), six urban regions were analysed under this title. In this first systematic examination, Hall treats the world cities predominantly as internationally oriented national metropolitan centres of the industrial age. It was only during the 1980s that world cities began to be seen in a different light. Based on historical work from the Annales school, theoretical insights derived from world-systems analysis and explorations of the New International Division of Labour (NIDL) (Fröbel, Heinrichs and Kreye, 1980), a new generation of urban theorists began to think of global cities as articulators of international and global economies. Accordingly, Michael Timberlake (1985, p. 3) explained that ‘processes such as urbanization can be more fully understood by beginning to examine the many ways in which they articulate with the broader currents of the world-economy that penetrate spatial barriers, transcend limited time boundaries and influence social relations at many different levels’.

Work on historical tendencies of global urbanization had laid the groundwork for understanding city systems as global and subject to long-term and macro-geographical shifts in the capitalist accumulation process. Writing in this tradition, Christopher Chase-Dunn examined the relationships between the expanding boundaries of the world system and the system of cities since AD 800 (Chase-Dunn, 1985). In a related fashion, some global city researchers have pointed to the complex colonial and post-colonial histories as well as the long trajectories of world city formation. Economic specialization has long been known to be the basis of world market-oriented urbanization, which propelled financial nodes such as Amsterdam, London or New York or industrial centres such as Leiden, Manchester, and Houston into the rank of leading world cities in subsequent historical periods (Nestor and Rodriguez, 1986). Defying any tendency to see global cities as a product of recent shifts in the world economy, Janet Abu-Lughod, for example, has argued that New York City has been a global city from its very inception as Dutch, and later English colonial outpost, and certainly as an industrial and financial powerhouse of the nineteenth and twentieth centuries (Abu-Lughod, 1999). Similarly, Anthony King (1990) has presented the global city formation of London as a complex process of the city’s history as a colonial centre.

Still, the case can be, and has been, made to see global cities in their current form as a product of today’s period of globalization. Brenner and Keil have suggested that one could see the emergence of a New International Division of Labour and the crisis of Atlantic Fordism in the 1970s and 1980s as the starting points for this round of world city formation (Brenner and Keil, 2006, pp. 8–10). At the outset of this line of reasoning was the publication of John Friedmann and Goetz Wolff’s seminal article in 1982 under the title ‘World City Formation: An Agenda for Research and Action’. In this influential piece, which arguably laid the foundation for an entire industry of global cities research, Friedmann and Wolff pointed
to a network of global cities that spanned the globe as the skeleton of the global economy. They suggested that '[t]he world city “approach” is, in the first instance, a methodology, a point of departure, an initial hypothesis. It is a way of asking questions and of bringing footloose facts into relation’ (Friedmann and Wolff, 1982, p. 320). Observing the emerging globalized world economy with its central actors, the TRANSTATIONAL CORPORATIONS, Friedmann and Wolff put forth the hypothesis that there would be a hierarchical system of urban regions, in which this world economic system would find its most typical socio-spatial expression. They assumed that ‘a small number of massive urban regions that we shall call world cities’ would be at the apex of this hierarchy (Friedmann and Wolff, 1982). They present the world cities as a flexible and ever-changing group of command centres of the world economy. The extent and nature of their integration into that economy can only be determined through empirical research in each city. The rapid changes that these urban regions are going through can specifically be studied in the areas of economic, social and physical RESTRUCTURING. Political conflict at various scales of the formation of the world city can be expected and is itself productive of the world city. In particular, the gulf between the globalized ‘citadel’ of the elite and the ‘ghetto’ of the popular classes will continue to widen and create tension in the political landscape of the global city. In 1986, John Friedmann added a more precise taxonomy of global city development, as he presented seven interrelated theses that added up the ‘world city hypothesis’:

1. The form and extent of a city’s integration with the world economy, and the functions assigned to the city in the new spatial division of labour, will be decisive for any structural changes occurring within it.
2. Key cities throughout the world are used by global capital as ‘basing points’ in the spatial organization and articulation of production and markets.
3. The global control functions of world cities are reflected in the structure and dynamics of their production sectors and employment.
4. World cities are major sites for the concentration and accumulation of international capital.
5. World cities are points of destination for large numbers of both domestic and/or international migrants (see migration).
6. World city formation brings into focus the major contradictions of industrial capitalism – among them spatial and class polarization.
7. World city growth generates social costs at rates that tend to exceed the fiscal capacity of the state.

Friedmann also impacted the way in which from now on world cities would be viewed by proposing a powerful image of networked interconnectedness showing the articulation of primary and secondary world cities in the core and the semi-periphery. The tremendous impact of the ‘world city hypothesis’ was subject to an international conference in 1993, from which the first multidisciplinary collection of global city essays was drawn (Knox and Taylor, 1995). In a review of the empirical and theoretical work done since his methodological intervention from 1982, Friedmann detected a lively PARADIGM that had grown from the original propositions (1995).

In the meantime, Saskia Sassen had published The global city: New York, London, Tokyo (2001 [1991]), which made her instantly the most prominent scholar in the rapidly expanding field. In this and subsequent publications, Sassen drew attention to the global city as a production site of the kind of internationally oriented business services that pushed for dominance in the global economy. These producer services (finances, law, marketing, advertising etc.) relied on regional production complexes, which remained tangible and led to more metropolitanization and urbanization despite the increased availability of networked electronic means of communication, which suggested the growing independence from fixed spatial arrangements. While The global city focused on the cities at the top of the global hierarchy – New York, London, Tokyo – Sassen expanded her argument in a short but incisive book Cities in a world economy (2006 [2000]), which identified and isolated specific strategic places where the globalized economy is taking shape: EXPORT PROCESSING ZONES, offshore banking centres, high-tech districts and global cities. Sassen insists on the interdependence of these disparate spaces as much as on the regional economy being the basis of the global city. Scott (2001, p. 4) similarly suggests that global city-regions serve ‘as territorial platforms for much of the POST-FORDIST economy that constitutes the dominant leading edge of contemporary capitalist development,
and as important staging posts for the operations of multinational corporations’. Sassen’s work on the global city has also strongly emphasized the social and political aspects of global city formation as she has consistently asked ‘whose city’ the global city is: Will the constant pressure for commodified and gentrified (see GENTRIFICATION) elite space or new citizenship claims by the ‘Othered’ majorities of the immigrant labour forces of the typical city prevail (Sassen, 1996)?

Proponents of the world city thesis have often been criticized for not providing conclusive data on the existence of a distinct set of global cities. The GaWC (Globalization and World Cities) research group at Loughborough University was set up in the late 1990s to rectify this deficit and to produce systematic empirical research on global city interconnectedness. On the basis of this research, Peter Taylor has recently provided the synthetic World city network (2004), in which he painstakingly prepares a massive pool of quantitative data to produce the first comprehensively researched and thoroughly theorized study of the network of global cities from a large variety of methodological angles. As Taylor (2004b, p. 21) argues, ‘The world city literature as a cumulative and collective enterprise begins only when the economic restructuring of the world-economy makes the idea of a mosaic of separate urban systems appear anachronistic and frankly irrelevant.’

The world city literature is not without its detractors. On the one hand, a group of seasoned urban theorists have criticized the exclusiveness of the global city hypothesis, which ostensibly seems to pay too little attention to the ‘ordinary cities’ (Amin and Thrift, 2002) that continue to be the majority of urban places. Michael Peter Smith (2001a) has denounced the structuralist bias of the world city debate and has instead proposed the notion of ‘transnational urbanism’, which explicitly includes reference to the grassroots processes that constitute the global city. Peter Marcuse and Ronald van Kempen have criticized the apodictic assumptions of global city research, which allegedly expects similarly polarizing socio-spatial effects everywhere, and have instead proposed a multidimensional and more diversified view of ‘globalizing cities’ of all sorts (2000, 2003). A younger group of post-structuralist geographers have meanwhile critiqued the global cities literature from the point of view of globalized CULTURE (Flusty, 2003) and agency (R.G. Smith, 2003d). Writing from a standpoint of urbanization in the global SOUTH, Jennifer Robinson (2002) has pointed out that the literature on world cities has a clear bias towards Western standards: ‘The world city approach assumes that cities occupy similar placings with similar capacity to progress up or fall down the ranks. . . . A view of the world of cities thus emerges where millions of people and hundreds of cities are dropped off the map of much research in urban studies, to service one particular and very restricted view of significance or (ir)relevance to certain sections of the global economy’ (Robinson, 2002). Despite these critiques, global city research is alive and well, and continues to produce a rich output of empirical work and theoretical insights. The breadth of the work produced under this banner has recently been published in a reader (Brenner and Keil, 2006).

Brenner and Keil (2006); Friedmann (2002); Sassen (1999, 2002). The GaWC (Globalization and World Cities) website (http:www.lboro.ac.uk/gawc/) presents a wide variety of bibliographies, research bulletins, project descriptions, data sets and web links related to research on global and world cities.

**global commons** This concept emerges from the traditional commons used by a local community (see COMMON PROPERTY REGIMES), but also includes elements of free market ENVIRONMENTALISM (Rose, 1999a). The notion of ‘commons’ is expanded to the global scale to address concerns about the environmental destruction of the oceans, atmosphere, forests, Antarctica and BIODIVERSITY caused primarily by open access beyond the jurisdiction of NATION-STATES. In essence, the concept seeks to make modern humans, like traditional villagers, responsible for the commons so that it does not deteriorate due to neglect or exploitation. The concept has been applied to the oceans to prevent overfishing, to Antarctica and to outer space, which recognize these locations as the ‘common heritage of (hu)mankind (CHM)’ (in Whatmore, 2002a, p. 104). Since the emergence of issues such as ozone depletion and global warming (see GLOBAL WARMING), the concept is also applicable to the atmosphere. Attempts have been made to construct the world’s BIODIVERSITY, including gene pools, as global commons. This can be understood as an attempt to preserve original NATURE against the ENCLOSURES that enable PROPERTY rights to be exercised, but with genetic
The concept of a ‘global commons’ requires international agreements to be enacted in national legislation. Whatmore (2002a, p. 107) questions the global commons approach in relation to genetic material, and notes that legal arrangements for the proposed global commons, which unravelled, must be understood as emerging from ‘amidst, rather than “outside”’, the spatial practices of national sovereignty and private property. The necessity and the ability to include air, water and other environmental considerations within a form of property rights is contentious. Rose (1999a, p. 50) questions the necessity of a ‘global commons’ approach, when many of the so-called global problems ‘have components that are much more localized’. She challenges Garrett Hardin’s largest issue for the global commons – that is, population growth (see Population Geography) – and suggests that it is the impacts of population growth (specific pressures on specific resources) that should be managed at a local level.

Global Positioning Systems (GPS)

The most widely known Global Positioning System (GPS) consists of 24 satellites, orbiting the Earth twice daily at a height of 200 km, used to find locations and to geocode data (see Geocoding). It was developed by the US Department of Defense and is managed by the US Air Force. A similar system, GLONASS (Global Navigation Satellite System), is operated by the Russian Federation. The European Union and Space Agency are developing Galileo, to be deployed in 2010 as a service independent of, but interoperable with (see Interoperability), both GPS and GLONASS.

The basic idea of a space-borne positioning service is that at least four of the system’s satellites will be above the local horizon at any given time or location on the Earth’s surface. The GPS receiver identifies a signal from those satellites, which contains information about each satellite’s orbital position and the time of the signal’s transmission. From these data and by trilateration (triangulation), the coordinate location and the elevation of the receiver can be calculated. In practice, built structures and vegetation canopies may obscure the line of sight between GPS receivers and satellites, reducing the accuracy of the measured location. Three satellites need to be visible to calculate location; four if elevation is also required (Clarke, 2003; Longley, Goodchild, Maguire and Rhind, 2005).

GPS readings typically are accurate to about 5–25 m: horizontal accuracy is generally greater than vertical accuracy. A problem is the distortion of the satellite’s signal as it passes through the atmosphere. The effects of this can be measured at fixed receivers where the locations given by the GPS are compared against their known positions, communicating any correction to calibrate GPS receivers nearby (a process known as differential GPS). An extension to this approach is to upload the information back to satellites for automatic correction (a Wide Area Augmentation System). However, no positioning service is absolute: it depends on the datum (model of the Earth’s shape) that is used. For GPS, this is the World Geodetic System 1984 (WGS84). Further errors will arise as this is converted to a local datum or coordinate system (notably when the three-dimensional model is projected onto a two-dimensional grid).

GPS is popular for in-car ‘satellite navigation’ and likely to be integrated more fully with portable communication and computing technologies such as mobile telephones and PDAs (Personal Digital Assistants), further fuelling the growth of location-based services, including ‘Where am I?’ or ‘Where’s my nearest ...?’ queries. GPS can enable personal navigation and discovery, and have clear social benefits (in search and rescue and emergency management, for example). However, because people might be tracked and located, so GPS
GLOBAL WARMING

Global warming is the increase in global temperature resulting from human activities that 'enhance' (exacerbate) the so-called natural 'greenhouse effect'. The term 'climate change' (see CLIMATE) is used increasingly, because although the global impact is warming, impacts vary throughout the world. Human-induced CLIMATE change is seen by many environmentalists as the most serious environmental problem, because it exacerbates other environmental issues.

Greenhouse gases are mostly natural compounds (water vapour, carbon dioxide, methane and nitrous oxide) that allow the Earth's atmosphere to trap heat released as longwave energy from the Earth's surface. This process, called the greenhouse effect, means that the earth is 33°C warmer than expected given its distance from the sun. At an average temperature of 15°C, the Earth supports many lifeforms.

The Intergovernmental Panel on Climate Change (IPCC) has provided scientific analyses of various greenhouse scenarios to inform the United Nations Framework Convention on Climate Change (1992) and the Climate Change Convention in Kyoto in 1997 (O'Neill, Mackellar and Lutz, 2001). The Kyoto Protocol came into effect in February 2005, after ratification by 55 countries that were responsible for 55 per cent of emissions in 1990. The largest emitter of greenhouse gases, the USA, and the largest emitter per capita, Australia, rejected ratification. Concerns about the Kyoto Protocol range from weak targets and an emphasis on creating trading systems (see ENVIRONMENTAL ECONOMICS), to its exclusion of rapidly developing economies such as China and India. There are also issues of 'baseline inflation'. The choice of 1990 as a base year meant that pollution from redundant heavy industry in the former East Germany was included in the base figure. Under the Kyoto Protocol, the Annex One (developed) countries agreed to an average reduction of 5.2 per cent of greenhouse gas emissions from a base year of 1990 by 2008–12. Australia secured an 8 per cent increase in emissions, including foregone land clearing (Hamilton, 2001).

There have been natural cooling and heating periods throughout the Earth's history, but the IPCC found that 'most of the warming observed over the past 50 years is attributable to human activities' (IPCC, 2001, p. 10). These include increased levels of carbon dioxide (coal burning, transport and clearing of forests), methane (burning natural gas, seepage from landfill sites, rice paddies and cattle) and nitrous oxide, mainly through agricultural activities (see Munasinghe and Swart, 2005). The impacts include rising sea levels and changes in the location, intensity and frequency of cyclones, droughts and floods. The changes are yet to be fully understood, because of the lag time between emission and cumulative impacts. While initial predictions of global warming have been lowered, there is uncertainty about the significance of clouds, the operations of ocean currents and the threshold levels of ecosystems. What is certain is that emissions of carbon dioxide and some other greenhouse gases are increasing, that they have a long lifetime, and that the average temperature of the Earth is about 0.7°C warmer than 100 years ago. While these processes are still occurring, lowering the initial predictions merely means that the impacts will be delayed by a few years.

globalization A big buzzword in political speech and a ubiquitous analytical category in academic debate, globalization operates today rather like MODERNIZATION did in the mid-twentieth century as the key term of a master discourse about the general state of the world. The most common political version of the discourse depicts globalization as an unstoppable process of global INTEGRATION, a supposedly inevitable process that while being driven by free market CAPITALISM also necessitates all the free market reforms of NEO-LIBERALISM. Here, for example, is Thomas Friedman (1999, pp. 7–8), a columnist of the New York Times who has made a name for himself by interpreting practically any event anywhere in the world through this same simple discourse. Globalization, he says,

involves the inexorable integration of markets, nation-states, and technologies to a degree never witnessed before – in a way

Suggested reading
Brimicombe (2006); Monmonier (2004).
that is enabling individuals, corporations and nation-states to reach around the world farther, faster, deeper and cheaper than ever before. The driving idea behind globalization is free-market capitalism – the more you let market forces rule and the more you open your economy to free trade and competition, the more efficient and flourishing your economy will be.

There is both a historical irony and a logical paradox in this sort of argument.

The irony is that while Friedman and others hype the new-ness of globalization to promote free market capitalism, they forget that in the middle of the nineteenth century global economic integration was depicted in very similar ways as a prelude to advancing a defiantly anti-capitalist Communist manifesto. In their famously lyrical account of the globalizing activities of the capitalist business class (the ‘bourgeoisie’), Karl Marx and Friedrich Engels argued thus that:

The need of a constantly expanding market for its products chases the bourgeoisie over the entire surface of the globe. It must nestle everywhere, settle everywhere, establish connections everywhere. The bourgeoisie has, through its exploitation of the world market, given a cosmopolitan character to production and consumption in every country. To the great chagrin of reactionaries, it has drawn from under the feet of industry the national ground on which it stood. All old-established national industries have been destroyed or are daily being destroyed. They are dislodged by new industries, whose introduction becomes a life and death question for all civilized nations, by industries that no longer work up indigenous raw material, but raw material drawn from the remotest zones; industries whose products are consumed, not only at home, but in every quarter of the globe. In place of the old wants, satisfied by the production of distant lands and climes, in place of the old local and national seclusion and self-sufficiency, we have intercourse in every direction, universal inter-dependence of nations. (Marx and Engels, 1998 [1848], p. 38)

Marx and Engels saw these interdependencies forged by capitalist globalization as leading ultimately to a global revolution by the workers of the world. By transcending local loyalties, increasing competition and intensifying exploitation, globalized capitalism would, they thought, create a globally united working class that would eventually revolt. This global revolution has still not happened, but the logical steps in the argument made by Marx and Engels were clear. By contrast, the contemporary argument that globalization is inexorable and yet necessitates reform is paradoxical. Global integration cannot be inexorable exactly if politicians and pundits have to keep promoting neo-liberal policies as the only way for it to function effectively. Nevertheless, this is precisely what they have been doing from the late 1970s onwards (see Harvey, 2005). ‘There Is No Alternative’ to free market policies, argued the British Prime Minister Margaret Thatcher in the 1980s, and, following her lead, TINA-touts the world over have endlessly repeated the mantra that globalization is inevitable and that it necessitates neo-liberal policy-making (e.g. Bhagwati, 2004; Wolf, 2004; Friedman, 2005). In the context of this instrumental use of globalization in creating a taken-for-granted world for policy-makers, there have been four main academic responses.

The first and most sceptical scholarly approach to globalization has been to argue that it is nothing but hype. Hirst and Thompson (1996) have suggested in this way that globalization is a myth, and that the picture of integration proceeding farther, faster, deeper and cheaper than ever before is empirically unsound. Against the claim that globalization is new, they highlight how significant forms of globe-spanning economic integration existed in the first decades of the twentieth century as a result of Imperialism and the other nineteenth-century economic developments noted by Marx and Engels. Against the claim that corporations have become stateless engines of border-crossing enterprise, they show how even large Transnational Corporations remain shaped by national supports and norms. And against the TINA-tout promotion of free market fundamentalism, they argue that policies that are not neo-liberal can still provide successful models of national development. However, in attempting to counter the hype, Hirst and Thompson miss many of the ways in which new networks have expanded and deepened global interdependency from the 1970s onwards.

Charting the development of global networks over time has in turn been the basis of the second main academic approach to globalization. Perhaps the most exhaustive examination available defines globalization thus in
GLOBALIZATION

terms of the extension, acceleration and intensification of consequential worldwide interconnections (Held, McGrew, Goldblatt and Perraton, 1999). The four authors argue that if globalization is conceptualized as ‘the widening, deepening and speeding up of global interconnectedness’ (p. 14), it is also possible to pick it apart as ‘a process which embodies a transformation in the spatial organization of social relations and transactions – assessed in terms of their extensity, intensity, velocity and impact – generating transcontinental or inter-regional flows and networks of activity, interaction and the exercise of power’ (p. 16). The precision of this approach is useful insofar as it provides clear parameters for assessing just how far global integration dynamics have created globally shared forms of common fate. They themselves also provide tremendous amounts of empirical data showing the changing extensity, intensity, velocity and impact of different sorts of space-spanning networks over time. However, their approach has two limitations.

First, it obscures the ways in which global interconnections can also create deeply divergent global fates, or what critics of cosmopolitanism and other idealistic accounts of transnationalism describe as discrepant cosmopolitanisms (Robbins, 1998). These discrepant communities are all also underpinned by global interconnections, but in ways that create vastly varied fates ranging from the soft cosmopolitanism of wealthy migrants and transnational capitalists (Sklair, 2001; Calhoun, 2003; Mitchell, 2003), to the carceral cosmopolitanism of those imprisoned in global spaces of exception (see exception, spaces of) (Gregory, 2004b; Sparke, 2006), to the critical cosmopolitanism of grassroots globalization activists and associated anti-neoliberal NGO networks (Routledge, 2003; Sparke, Brown, Corva et al., 2005). Part of the reason why Held and co-authors tend to downplay such discrepancies between global networks may in turn be traced to a second limitation with many network-centric accounts; namely, their relative inattention to the uneven development of spatial organization itself. This weakness is often amplified in assessments of globalization that stress what the sociologist Anthony Giddens (1984) once called time–space distanciation; that is, the establishment of space-spanning relations of regulation, trust and interaction between people at a distance. Commentators from across the political spectrum, Giddens himself amongst them, have thus unfortunately tended to describe globalization as some sort of end to geography in which time–space distanciation has reached its final fulfilment in the creation of a smooth, borderless, post-national, supraterritorial global landscape or, what Thomas Friedman has recently described as a ‘flat’ world (see, e.g., Giddens, 1995; Ohmae, 1995; Appadurai, 1996; Hardt and Negri, 2000; Scholte, 2000; Friedman, 2005).

In response to all the pre-emptive epitaphs to geography, a third more geographically sensitive approach to globalization highlights how capitalism has created new forms of uneven development involving both deterioratorialization and reterritorialization. David Harvey (1989b, 2006b) has argued thus that while capitalists shrink distance and create time–space compression because of their deterioratorializing efforts to reduce the frictions of distance, they also episodically require a reterritorializing spatial fix in which fixed capital investments are made and through which crises of over-accumulation can be temporarily resolved (see also Harvey, 1999 [1982]). This argument has also led him to interpret the recent resurgence of American empire in terms of the tensions between place-transcending and place-remaking dynamics on a global scale (Harvey, 2004b). Drawing further attention to the changing shape of American global place-making in particular, many other academics have highlighted how flat-world visions of globalization obscure the asymmetries and attendant geopolitics of today’s US-centric global order, including the exceptional privileges reserved by the USA within global governance institutions such as the international monetary fund and the world bank (Anderson, 2002b; Gowan, 2003; Peet, 2003; Agnew, 2004; Pieterse, 2004; Smith, 2004; Sparke, 2005). In a different way, research on the governance of international borders has shown how the border-softening emphasis in flat-world business discourse also obscures diverse forms of contemporary border hardening (Nevins, 2002; Newstead, Reid and Sparke, 2003; Sparke, Sidaway, Bunnell and Grundy-Warr, 2004; Coleman, 2005; Sparke, 2006). Meanwhile, the ongoing need to track how business practices are themselves constantly reorganizing the geography of commodity chains has led yet other scholars to chart the unevenness of the global economic map of production, trade, distribution and consumption (e.g. Dicken, 2003; see also Mittelman, 2000). And it is this uneven and constantly shifting map that has in turn inspired interest in globalization as way of exploring reciprocal local–global relations that
avoids end-state end-of-geography ideas about global flattening (Swyngedouw, 2004).

With a related repudiation of what she calls an ‘impact model’ of globalization, the geographer Gill Hart’s recent work also illustrates a fourth form of academic response to globalization focused on how its hegemony as a neoliberal discourse both works and breaks down in practice (Hart, 2004). Hart argues that this hegemony serves amongst other things to make the forced privatization of public goods and spaces seem natural, and in response she suggests that ethnographies of the ties between different places and people can help denaturalize such dispossession (Hart, 2006: see also Tsing, 2004). Such counter-hegemonic critiques of neo-liberal globalization discourse have now developed a diverse set of complementary strategies for debunking TINA-tout inevitability ideology. Such strategies range from efforts to chart the emergence and marketing of globalization discourse as a form of ‘Globaloney’ or globalist common-sense (Steger, 2005; Veseth, 2005), to examinations of how it has been re-engineered and spread internationally by ‘World Bank Literature’ (Kumar, 2003), global business schooling (Roberts, 2004; Olds and Thrift, 2005) and business-funded think-tanks (Peck, 2001b, 2004), to studies of its uneven implementation in the actual organization of business practices themselves (Dicken, 2003; Ho, 2005), to research into its impact as a form of geo-economics that shapes both national and transnational statecraft (Smith, 2002; Roberts et al., 2003; Sparke and Lawson, 2003; Hay, 2004; Jones and Jones, 2004; Gilbert, 2005), to feminist investigations of the masculinism of arguments about the inevitability of global capitalist penetration (Gibson-Graham, 1996; Massey, 2005). Such examinations of the performance of globalization discourse can bring it down to size and allow academics and their audiences to see it ‘stutter’ (Larner and Walters, 2005, p. 20), but, just as importantly, they also clear the way for investigations of the actual power-geometries of globalization in the lived worlds beyond the buzzword and its flatworld imaginative geography (see also geographical imaginary).

globe  A solid sphere; in geography, the globe refers to the Earth itself or a physical model of it (although the Earth’s actual form as an oblate spheroid has been known since Newton theorized it in his Principia and French field scientists demonstrated it in 1736). The globe is a conventional symbol of geographical science, the geographer traditionally pictured measuring distances with dividers placed on a terrestrial globe. Celestial globes showing the pattern of forms in the visible heavens have long been paired with geographical globes. Recognition of the Earth’s sphericity is dated to Eratosthenes (276–195 BCE), but only celestial globes survive from Antiquity, and were used in Chinese and Islamic science too. No terrestrial globes pre-date the European Renaissance, although it is a nineteenth-century myth that before Columbus the Earth was believed to be flat.

Construction of terrestrial globes is described in Ptolemy’s second-century AD book Geography, known in the West from the late fourteenth century. The earliest existing terrestrial globe dates from 1492, made by a Nuremburg merchant knowledgeable about Portuguese oceanic navigations. Circumnavigation of the globe in 1522 produced a scientific and diplomatic demand for model globes, although their bulkiness and the size required for detailed representation of seas and coasts severely limited their practical navigational use on board ship (Brotton, 1997). Globe sets of terrestrial, celestial and armillary spheres (see cosmography) were objects of beauty, status and display as much as scientific instruments (cf. scientific instrumentation) in the early modern world, and the largest globes were made for monarchs such as Louis XIV of France, or as public spectacles; for example; in the great (‘world’) exhibitions of the nineteenth and twentieth centuries. The globe remains an icon of power as much as an educational object today, signifying control over the space that it represents. Model globes or globe images are thus common in advertising and entertainment as an indicator of international reach and significance, and are used by airlines, communications corporations and at self-consciously international events such as exhibitions, fairs and sports spectacles (Pickles, 2004).

The discourse of globalization draws on the idea and image of the globe as a symbol of connectedness and unity, drawing on an association of the globe image with cosmopolitanism. Since the appearance of satellite images of Earth, ‘thinking globally’ has become a mantra of environmentalist discourse, while the globe has become in some respects a banal object, appearing on balloons, key fobs and other playthings (Cosgrove, 2001).

Cosgrove (2001); Woodward (2006).

**glocalization** This awkward adversary of spell-check programs globally has been used in three quite different ways in debates over GLOBALIZATION. First, it has proved useful for critics of what Gillian Hart calls the ‘impact model’ of global economic integration (Hart, 2003). Challenging the idea of global CAPITALISM simply entering and transforming local REGIONS, geographers such as Erik Swyngedouw have thus invoked glocalization to describe the dialectical LOCAL–GLOBAL RELATIONS through which local regions mediate and change global processes even as they are remade and rescaled themselves (Swyngedouw, 2001, 2004a, 2006). Second, social theorists who are interested in the development of contemporary cultural hybrids refer to glocalization as a way of examining syncretic mixes and other forms of so-called heterogenization that are obscured by visions of global cultural homogenization (Featherstone, 1995; see Hybridity). And third, the most banal appeals to glocalization are from business strategists who talk about the need to ‘glocalize’ big brands so that they can be better targeted at particular local markets (e.g. vegetarian Big Macs in India). MS

**governable space** Geographical space shaped and organized in ways that make it amenable to technologies of government. The term was used by Rose (1999c) in his development and extension of Foucault’s ideas about government and GOVERNMENTALITY. Rose argues that ‘governing does not just act on a pre-existing thought world with its natural divisions’; rather, ‘to govern is to cut experience in certain ways, to bring new facets and forces, new intensities and relations into being’ (1999, p. 31). This involves ‘the making up of governable spaces: populations, nations, societies, economies, classes, families, schools, factories, individuals’ (1991, p. 31). Governable spaces are not, however, ‘fabricated counter to experience’. On the contrary, they ‘make new kinds of experience possible, produce new modes of perception, invest percepts with affects, with dangers and opportunities, with saliences and attractions’ (1999, p. 32; cf. AFFECT). Rose distinguishes three dimensions to the analysis of governable space (1999, pp. 34–40). These are:

1. **Territorializing governmental thought** through, for example, the formation of national ‘societies’ and ‘TERRITORIES’. Smaller-scale territorializations such as the CITY and the REGION can also be traced (cf. TERRITORIALITY).

2. **Spatializing the gaze of governors** through technologies of VISION AND VISUALITY, and particularly CARTOGRAPHY and the use of CARTOGRAPHIC REASON (Pickles, 2004).

3. **Modelling the space of government**. This typically takes two forms: isotropic models and depth MODELS. Isotropic models conceptualize space as ‘the same everywhere’. This might involve the use of plans, grids and surveys to tame space and make it comprehensible to rationalities of government. Isotropic models are particularly important in the BIOPOLITICS of COLONIALISM, where they enabled the extension of Western forms of governmental rationality and judicial SOVEREIGNTY into the spaces of racialized ‘Others’ (Olund, 2002). The model of POLITICAL ECONOMY, on the other hand, involves a depth model with ‘hidden’ determinants, such as the ‘law’ of supply and demand, that can be distinguished from the surface appearance of things.

Space is thus made governable through the application of specific technologies and practices, including population monitoring, statistics, SURVEYING and CADAstral MAPPING. On the other hand, despite the prevalence of such abstract and calculative techniques, bodily VIOLENCE remains a widespread mechanism for the production of governable space, as shown by Watts’ (2006) study of the Niger Delta. JPa

**governance** A term that is sometimes used loosely to mean simply government, but more precisely refers to the process of social and economic coordination, management and ‘steering’. Under this umbrella definition may be found a number of sometimes contradictory usages. At its broadest, governance can mean any kind of coordination between organizations, parts of organizations, groups and individuals, ranging from hierarchical ‘command and control’ systems to decentralized forms of interaction (such as MARKET forms of EXCHANGE). Most commonly, however, governance refers to forms of inter-organizational
coordination modelled neither on hierarchies nor on markets but on networks, especially where these are ‘self-organizing’. For Jessop, governance is ‘the “self-organization of inter-organizational relations” ’ (1997, p. 59), while Rhodes defines it as ‘self-organizing, interorganizational networks’ (Rhodes, 1997, p. 53). Rhodes expands this definition as follows:

(1) Interdependence between organizations. Governance is broader than government, covering non-state actors. Changing the boundaries of the state meant the boundaries between public, private and voluntary sectors became more shifting and opaque.

(2) Continuing interactions between network members, caused by the need to exchange resources and negotiate shared purposes.

(3) Game-like interactions, rooted in trust and regulated by rules of the game negotiated and agreed by network participants.

(4) A significant degree of autonomy from the state. Networks are not accountable to the state; they are self-organizing. Although the state does not occupy a sovereign position, it can indirectly and imperfectly steer networks.

Such definitions make it possible to speak of a shift from government (coordination through hierarchy) to governance (coordination through networks). Like Rhodes, most writers on governance take the view that networks may include a wide variety of organizations and are not limited only to state institutions. Indeed, one of the central propositions of governance research is that those involved in the generation and implementation of public policy are not only the formal agencies of government, but may include private firms, NGOs, voluntary organizations, faith- and community-based groups and grassroots campaigns. In part, this merely recognizes the complexity of social systems and the steering of societal development have never been the responsibilities of the state alone. Most writers, though, go further and argue that the state has become less prominent and that non-state organizations have become relatively more important within the coordination process.

Reducing the role of the state has also been an important goal of efforts by international development organizations to promote what they term ‘good governance’. The World Bank and the INTERNATIONAL MONETARY FUND in particular have often made development assistance to poorer countries conditional on programmes of public-sector reform. In this context, ‘good governance’ involves transparency and accountability in public administration, the efficient use of public resources, participation in decision-making and respect for the rule of law. Critics (e.g. Evans, 2004) object that these reforms require governments in developing countries to adopt inappropriate Western models of public administration, to reduce public expenditure and to privatize the provision of goods and services, leading to detrimental impacts on the lives of poorer people (cf. PRIVATIZATION). In both developing and developed countries the shift from government to governance and the increased public role of non-state actors has raised concerns about the lack of democratic control over decision-making and policy implementation.

Research on the geographies of governance has focused on two main overlapping themes:

(1) The role of networks. Rhodes’ own work on ‘policy networks’ has been adapted and supplemented by other approaches to examine, for example, processes of urban development (McGuirk, 2000). Research has also focused on the growing use of inter-agency partnerships as an institutionalized expression of networked governance (Geddes, 2006) and on inter-urban networks (Leitner, Pavlik and Sheppard, 2002).

(2) The ‘re-scaling’ of governance. Early accounts of the shift from government to governance linked it to the ‘hollowing-out’ of the state, which was said to involve the loss of central state functions to both supra-national scales (e.g. the European Union) and sub-national scales (e.g. autonomous regions, local bodies). The nature of governance processes at sub-national spatial scales has been examined in detail in URBAN AND REGIONAL GEOGRAPHY (Painter and Goodwin, 2000; Jones, 2001; Brenner, 2004). One strand of this work focuses explicitly on ‘multi-level governance’, highlighting relations between local or regional, national and supranational scales (e.g. Bulkeley and Betsill, 2005).

governmentality A concept devised by the French thinker Michel Foucault (1926–84) to describe the practices of government of a population as they emerged in Europe in the modern period. Foucault used the term to describe the particular practices of the state under the organizational regime that he termed ‘security’. Government is thus not a property of the space, but the performance of its power in a historically and geographically specific way. Foucault’s notion of disciplinary power required the enclosure, circumscription, partition and control of space, while security was concerned with opening up spaces to allow circulation and passage. This requires regulation, but of a minimal kind. In Foucault’s terms, discipline is isolating, working on measures of segmentation, while security seeks to incorporate and to distribute more widely (see also security). The practices particular to this model of governmental organization are what Foucault means by governmentality.

Foucault’s researches on governmentality emerged in the late 1970s as part of his project of understanding the birth of the modern human subject. He was therefore interested in the way in which humans – both as individual bodies and as the collective body of population – were governed. This government was both government of the self by the self, to which his last works on technologies of the self and ethics speak, and government by others. His works on governmentality itself, in lecture courses from 1978 and 1979 (Foucault, 2007 [2004], 2008 [2004]), from which the lecture ‘Governmentality’ (1991) is extracted, concentrate on government as it is exercised in political sovereignty, political rule.

Foucault traces the emergence of governmentality historically, suggesting three main sources: the Christian pastoral, diplomatic–military techniques in early modern Europe and the police. The first provides a model for codes of conduct and the concern for the population as a flock; the second looks at the techniques of external governmental relations; and the third at internal mechanisms of the policing or ordering of a society. Foucault understands the ‘police’ as something much more than a uniformed force for the prevention and detection of crime but, rather, as what allows the functioning of a society or polity as a whole (cf. policing). In this sense it is closer to the analyses of Hegel, Adam Smith or Adam Ferguson, with a concern for things including public infrastructure such as roads and bridges, pricing mechanisms, and public health and property. In each, he is concerned with how government is interested in ‘each and all’ – individual bodies subject to governmental procedures, and the population measured and calculated through larger scale campaigns (Foucault, 1988). In both, the practices are tied to the development of knowledge, which in turn conditions the practices themselves.

In order to understand the transition from earlier sovereign models of political power to discipline and security or government, Foucault does not propose a linear narrative. Rather, he suggests that we understand this model as a triangle of sovereignty–discipline–government (governmental management), whose primary target is population, whose principal form of knowledge is political economy, and whose essential mechanism or technical means of operating are apparatuses of security. Conceiving of these three ‘societies’ not on a linear model but, rather, as a space of political action allows us to inject historical and geographical specificity into Foucault’s narrative. Different places and different times might be closer to one node or another, while recognizing that this is a generally useful and transferable model of analysis. Although Foucault’s work is largely tied to France and Germany, and dependent on better known historical transitions such as that between feudalism and capitalism, the birth of modern philosophy and schisms in the church, some writers have used his ideas to look at places that did not follow such chronologies.

Foucault’s work on governmentality has been widely taken up across the human sciences, including human geography. Key works by his colleagues in France have been collected in The Foucault effect (Burchell, Gordon and Miller, 1991) and collections of writings developing and augmenting his researches have continued to appear (see, e.g., Barry, Osborne and Rose, 1996; Dean, 1999; Walters and Larner, 2004). Geographers have looked at a range of spaces through a governmentality perspective, including those that exceed Foucault’s largely eurocentric perspective (Braun, 2000; Hannah, 2000, Corbridge, Williams, Srivastava and Veron, 2005). These have largely been developments of the original lecture on the topic, and related writings (i.e. Foucault, 1988), so it is likely that the publication of the full lecture courses (Foucault, 2007 [2004], 2008 [2004]), with their rich analyses, will
There have been two critical responses to this search, fastening on (i) its theoretical ambitions and (ii) its totalizing ambitions:

(1) There has been a continuing debate about the scope of theory in human geography. Few would advocate a return to the supposedly theory-less world of empiricism, but Ley (1989), in the spirit of Mills’ original objections, nonetheless complained of a fixation upon theory (or rather Theory): of the privilege accorded to the ‘theorization of theories’, second-order abstractions ‘doubly removed from the empirical world’, whose proliferation threatened to produce a disturbing fragmentation of geographical enquiry. Yet in the same year Harvey and Scott (1989) were exercised by what they saw as a withdrawal from ‘the theoretical imperative’ and, in consequence, the dissolution of intellectual enquiry into a host of empirical particulars. The fragmentation that dismayed both these responses (in different ways) was often the product of theoretical work conducted outside the confines of (and in large measure working against) Grand Theory: see, for example, historicism, postmodernism and post-structuralism. Hence Dear’s (1988) exuberant insistence that ‘there can be no grand theory for human geography!’ was coupled with an equally exuberant demand for human geography to engage with social theory. His intention was to fashion a human geography that was at once theoretically engaged and sensitive to empirical particularity – to ‘difference’. Similarly – but differently – Thrift (1996, p. 30; see also 2006) argued that a yet more ‘modest’ form of theorizing was needed to avoid a ‘theory-centred’ style of research ‘which continually avoids the taint of particularity’, though to his chagrin several critics plainly regard his own project of non-representational theory as yet another exorbitation of Theory with a capital T. Whether Thrift has successfully clipped the wings of Grand Theory remains an open question, but in any event Katz (1996) urged human geographers to find other ways of letting theory take flight. She recommended an openness to minor theory: subverting the claims to mastery registered by Grand Theory by working in the heterogeneous ‘spaces-in-between’ different traditions, by

Grand Theory A term devised by American sociologist C. Wright Mills (1959) to attack what he took to be the obsessive concern of post-Second World War social science with empty conceptual elaboration (‘the associating and dissociating of concepts’) at high levels of abstraction. In his view, Grand Theory was more or less severed from the concrete concerns of everyday life and largely indifferent to its immense variety in time and space. His main target was Talcott Parsons, another American sociologist and the architect of structural functionalism, against whom he insisted ‘there is no “grand theory”, no one universal scheme in terms of which we can understand the unity of social structure, no one answer to the tired old problem of social order’.

In geography, the postwar development of spatial science made similar promises to Parsons’, but about spatial rather than social order: indeed, Chorley and Haggett (1967) anticipated the construction of a ‘general theory of locational relativity’ and a unified spatial systems theory (see system). The critiques of structural functionalism (in the social sciences) and spatial science (in geography) did not lead to the demise of Grand Theory, however, so much as its reformulation. By the 1980s, so many other candidates had emerged that Skinner (1985) could write of ‘the return of Grand Theory’. These included critical theory, structuralism, structural Marxism and structuration theory, all of which left their marks on human geography. Indeed, Barnes and Gregory (1997a, p. 64) claimed that much of the late-twentieth-century history of Anglo-American human geography had involved ‘the search for a single or tightly bounded set of methodological and theoretical principles that, once found, would provide unity and intelligibility to the disparate material studied. When located, such principles would function as a kind of philosopher’s stone, transmuting the scattered base facts of the world into the pure gold of coherent explanation. No matter the kind of phenomenon investigated, it could always be slotted into a wider theoretical scheme. Nothing would be left out; everything would be explained.’

reinvigorate this sub-field (see Lemke, 2001; Elden, 2007b; Legg, 2007b).
activating the disjunctures and displacements between different voices and vocabularies, and so ensuring that theoretical work is ‘relentlessly transformative’ and elaborates ‘lines of escape’.

(2) There has been a parallel debate about the capacity of any single theoretical system to account for the world (cf. ESSENTIALISM; FOUNDATIONALISM). Many, perhaps most, human geographers seem to accept: (a) that no single theoretical system can possibly ask all the interesting questions or provide all the satisfying answers; and (b) that most scholars necessarily work in the spaces between overlapping, often contending theoretical systems, which redoubles the importance of theoretical critique to clarify dissonances, reveal erasures and evaluate consequences (Gregory, 1994, pp. 100–6). But these nostrums have neither soothed geographers’ anxieties nor dispelled their ambitions. Much of the controversy attached to Harvey’s historico-geographical materialism, for example, centres on his attempt to develop a totalizing critique through what his critics see as the annexation, incorporation and marginalization of other politico-intellectual traditions (Castree and Gregory, 2006). And while few geographers have pursued the Ariadne’s thread linking Humboldt’s grand eighteenth-century vision of the Cosmos to Chorley and Haggett’s twentieth-century vision of a unified field theory for Geography, there has been considerable interest in theoretical systems that trouble the divide between the human sciences and the natural sciences: for example, CHAOS THEORY and COMPLEXITY THEORY. If Manson and Sullivan (2006, p. 678) are right to describe complexity as ‘the grand theory to end all grand theories’, perhaps Grand Theory always rings twice. DG

**graph theory** A branch of mathematics that studies topological phenomena that can be represented by NETWORK diagrams comprising nodes and the links between them: the classic pioneering work was that of Leonhard Euler (1707–83) on the Königsberg bridge problem (see http://www.contracosta.cc.ca.us/math/konig.htm). TOPOLOGY refers to spatial connections and relationships that are unchanged after distortion: for example, Canada has a border with the USA regardless of which datum and MAP PROJECTION system is used to map the Earth. Graph theory was first deployed by geographers in the study of a range of network types – such as river systems and road networks (Haggett and Chorley, 1969) – but is widely deployed through the social sciences to study the structure and functioning of a range of social networks and how information flows through them (a field known as socio-metrics). (See also OPTIMIZATION.) RJ

**gravity model** A mathematical and statistical MODEL used to represent many types of SPATIAL INTERACTION and flow patterns in HUMAN GEOGRAPHY and REGIONAL SCIENCE (such as MIGRATION and commodity flows), and subsequently extended for use as a planning tool. The original formulation, as devised by members of the SOCIAL PHYSICS school, was based on an analogy with Newton’s equation of gravitational force:

\[ G_{ij} = \frac{gM_iM_j}{d_{ij}^2} \]

This can be interpreted as follows: the gravitational force \( G_{ij} \) between two masses \( M_i \) and \( M_j \) is proportional to a gravitational constant \( g \) and to the product of their masses \( M_iM_j \) and inversely proportional to the square of the distance between them \( d_{ij}^2 \). The analogy for migration was therefore given as

\[ F_{ij} = \frac{gP_iP_j}{d_{ij}^2} \]

where the migrant flow \( F \) from \( i \) to \( j \) was modelled as being proportional to the product of their populations and inversely proportional to the distance between them. In such an application, the constant \( g \) was empirically determined from the data set by simple arithmetic methods. At a later stage the model was fitted by REGRESSION methods in logarithmic form, and both \( g \) and the exponent for distance were empirically determined by calibration. This basic form of the model is unconstrained, and empirical studies demonstrated that the model fitted much better if origin and destination constraints (e.g. the total numbers of people starting or ending in each region) were incorporated. This was most effectively developed by Alan Wilson in his ENTROPY-MAXIMIZING formulation of the model, based on an analogy with statistical physics rather

**Suggested reading**
than Newtonian equations, and in this form it is widely used today. It may be used for the assessment of likely policy impacts by projecting changes to origin and destination totals, introducing different travel mode and pricing, and making the model dynamic. The gravity model approach has come under heavy criticism because of its mimicking of equations and models from physics, rather than being rooted in social science, but much recent work has shown how the various assumptions of the models (such as DISTANCE DECAY) may be derived from concepts of ACCESSIBILITY, UTILITY THEORY and INTERVENING OPPORTUNITY. The physical analogy is just that, an analogy and no more. LWH

green belt A designated area of land surrounding a built-up area, into which urban expansion is strictly limited by planning policies. Initially proposed as part of the GARDEN CITY movement, delimitation of green belts around all major urban areas was part of the innovatory procedures made mandatory under the UK’s 1947 TOWN AND COUNTRY PLANNING ACT, both to contain urban SPRAWL and to protect high-quality agricultural land plus that used for recreational and other amenity purposes. The proportion of the land surface designated as green belts has been substantially increased since, despite opposition from interest groups – such as development companies that want to build there in response to growing pressure for new housing, which governments instead wish to focus on ‘brownfield’ (i.e. redevelopment) sites within existing urban areas. The policy’s success has stimulated urban development beyond the green belts, leading to increased COMMUTING costs for many workers and casting doubt on the overall economic and environmental justification for the continued constraints (cf. COUNTER-URBANIZATION). Comparable policies have been instituted in many other countries. Rj

Green Revolution A term coined in the late 1960s to refer to the so-called miracle seeds – the high-yielding varieties (HYVs), and especially wheat and rice – that held out the prospect for spectacular increases in cereal production in the THIRD WORLD. Associated with 1970 Nobel Prize winner and crop geneticist Norman Borlaug, the term ‘Green Revolution’ continues to have wide currency 30 years after it was minted. Nonetheless, it remains somewhat controversial and indeed there is often little consensus on what the Green Revolution actually denotes. The adjective ‘Green’ implies, at least in our epoch, a sensitivity to SUSTAINABILITY (but ironically the ecological costs of the HYVs have been a purported major failing) and implicitly is opposed to ‘Red’ in a way which technical achievements – a technical fix – could banish not simply hunger but political unrest. In order to understand the origins and genesis of the ‘heroic age’ (Jirstrom, 1996, p. 15) of the Green Revolution between 1963 and 1970, the miracle seeds must be located on the earlier landscape of the COLD WAR, which embraces American IMPERIALISM in Vietnam, a Malthusian view of food shortages in the post-1945 period, and the recognition that the Green Revolution was wrapped up with US foreign policy and the perceived threat posed by poor peasants inclined towards SOCIALISM (cf. MALTHUSIAN MODEL).

The meaning of ‘Green Revolution’ remains a contested issue. The heart of the revolutionary thrust was quite simple: seeds plus nitrogen plus water would produce increased yields
per unit area. As a consequence, there is a narrow and broad interpretation of the technologies themselves. In the narrow sense, it consists primarily of the adoption of the new high-yielding varieties of wheat and rice and associated technologies. In the broad sense it includes not only this, but all other economic changes, as well as the social and cultural changes that either contributed to the technological and ecological changes or were derived from them (Leaf, 1984, p. 23).

The Green Revolution as a set of new production practices for the tropical or subtropical peasant or smallholder rested on the development of Mendelian genetics, applied plant breeding (led by the UK and the USA), fertilizer (the petrochemical industry) and the water development/irrigation technologies. The coordination between the biochemical, technological and social components embraced US philanthropic organizations, the US State Department and Third World governments. What began in the 1940s in Mexico under the auspices of the US government and the Rockefeller Foundation, focused on improving wheat, has grown in half a century to a massive multi-billion dollar network of international agricultural research centres (the Consultative Group of International Agricultural Research, CGIAR), administered by the World Bank and dealing with virtually all the major food complexes. HYVs are now grown worldwide – for example, 100 per cent of rice in China and Korea, and 70 per cent in India and the Philippines is miracle rice – and there is no question that the ability of food output to exceed population growth in the Third World since 1950 has been a function of the productivity gains of the Green Revolution (Lipton, 1989). But the Green Revolution, insofar as it is an example of applied plant breeding, has of course a long history – human history is synonymous with successive Green Revolutions, associated with the domestication of plants, with the European agricultural revolutions in the eighteenth century, the Chinese improved rice varieties of AD 1000 and so on – and is a process (still ongoing) rather than an event (Rigg, 1989).

If the Green Revolution was facilitated by new practices associated with plant breeding, soil fertility science and hydrological development, the genesis was stimulated by the activities of the Rockefeller Foundation in conjunction with the Office of Special Operations of the US Government in Mexico during the Second World War (Perkins, 1997). Whatever the intentions of the early plant breeders in Mexico, the combination of Malthusians thinking about food crises and the Cold War atmosphere favouring national security and the threat of peasant insurgency contributed mightily to the Green Revolution project, and to its subsequent backing and support by the Ford Foundation, USAID and the major Western donors. In the first phase of the Green Revolution, rice and wheat were the primary crops and Mexico and India its crucibles. The International Rice Research Institute (IRRI) was founded near Manila in 1960 and the Center for Maize and Wheat Improvement (CIMMYT) in Mexico in 1963. Today, there are 16 international agriculture research centres, focusing on potatoes, germ plasm collection, agro-forestry and tropical agriculture.

The research programme for HYVs brought together in university-type settings transnational conglomeres of scientists, which constituted sophisticated breeding programs. The IRRI, for example, built upon rice-breeding expertise and dwarf varieties from Taiwan and Japan to produce, through hybridization, new dwarf HYVs that were resistant to lodging, were sensitive to nitrogen fertilizers and that could be double or triple cropped through a reduction in the growing period. Its first success – IR-8 – was released in 1966 and spread rapidly through South and South East Asia. The diffusion of the seeds and mechanical packages (pump sets, small tractors) involved strong state intervention, typically involving new subsidies, credit, extension services, irrigation development and national breeding programmes. By the mid-1980s, more than half of the total rice in the area of the Third World was planted in HYVs (Lipton, 1989).

There has been considerable disagreement over the productivity increases attributable to HYVs. In one of the best-known and earliest reviews by UNRISD/UNDP, Griffin (1974) painted a bleak picture of the effects of HYVs between 1970 and 1974, arguing that there had been no Green Revolution in rice. A subsequent assessment by Michael Lipton (1989) in the mid-1980s showed that the output increases in wheat and maize were indeed dramatic (at least 4 per cent per year) and that those in rice were slower but no less substantial overall. Lipton pointed, however, to regional dilemmas – Africa was neglected on balance – and to the problems of equity within countries, which reflected disparities in irrigation development and water control investment. In the first phase of the Green
Revolution, a number of important problems emerged: first, increasing pest and weed problems; second, problems of storage and processing; and, third, ecological deterioration (especially loss of germ plasm, water depletion and toxicity). All of these direct and indirect consequences initiated a still ongoing debate over the consequences of HYVs (see Shiva, 1991, 1996).

At the heart of the impact question are equity, POVERTY and SOCIAL JUSTICE. In the early years, the adoption of HYV packages (and the recognition that the packages were not SCALE neutral) prompted much speculation about new forms of social differentiation among peasants, of class conflict between adopters and non-adopters, of deteriorating labour conditions, as HYVs were labour-displacing rather than labour-saving – of the ‘green revolution turning red’. As the Indian case shows, there was in fact no simple polarization of landholding, though there has been the consolidation of a class of increasingly commercialized and organized rich peasants who have benefited from the Green Revolution (these are the heart of the New Farmers Movement in India, which has changed the face of local and national politics: see SOCIAL MOVEMENTS). The impact on LABOUR MARKETS (new forms of MIGRATION, changing forms of labour permanancy and tenancy), on landholding (cf. LAND TENURE) and on social inequality is enormously complex, in part because of the linkages and off-farm employment (Hazell, 1987). On balance, the mechanization that has followed the HYV adoption has been labour displacing and has favoured those with concentrated capital displacement. New forms of inequality have emerged, but this is often attributed by the proponents of the HYVs to population growth and state rent-seeking rather than technology per se. The debate continues.

The Green Revolution has unquestionably increased food output per capita, but this has not necessarily increased food availability for the poor (Dreze and Sen, 1989), and nor has it improved the lot of the poor (Lipton, 1989). The first issue turns less on output than on availability and entitlements – in short, the social component of the Green Revolution (including land reform). The second speaks to the problems of both the uneven adoption of HYVs and the biases built into the breeding programmes themselves. The miracle seeds are often not pro-poor and do not speak to the circumstances of the land-poor and landless.

There is a debate over whether the Green Revolution has ‘ended’ in the sense that there are no new seed breakthroughs likely in the world STAPLE crops. The pessimists foresee a Malthusian nightmare of FAMINE and pestilence, compounded by the growth of Chinese staple food imports. Nonetheless, the Green Revolution has entered a second phase associated with the breakthroughs of molecular science and recombinant DNA. Here, the issue is increasingly the power of large transnational seed and pharmaceutical companies, who develop new crops with built-in requirements for particular inputs, and the intellectual property rights that attend to the concentration of power in AGROBUSINESS companies (Shiva, 1996). Genetically modified HYVs (whether soy or corn) have become part of an embattled agricultural landscape in which environmental questions have been tied to corporate power and the pressures exerted through the WORLD TRADE ORGANIZATION by First World states to liberalize protected agricultural sectors in the global SOUTH. Many of the most vociferous of the ANTI-GLOBALIZATION movements have often expressed concerns over the ways in which the second phase of the Green Revolution is now refiguring the international food order, now dominated by corporate power and a new round of privatized agricultural and seed technologies (Rosset, 2006). The current debates over farmer breeding rights, genetically modified crops and INTELLECTUAL PROPERTY RIGHTS suggests that the next Green Revolution will be as fraught as the first.

**greenhouse effect** See GLOBAL WARMING

**gross domestic product (GDP)** A monetary estimate of the value (at current market prices) of final goods and services produced within an ECONOMY (usually national) during a given period. Capital expenditure, indirect taxes and subsidies are excluded, as is the value of intermediate products (such as raw materials) which is included in the value of final goods. GDP is often favoured over GROSS NATIONAL PRODUCT (GNP) as a measure of economic activity because it excludes net income from abroad. International comparisons of GDP, either in aggregate or per capita, are difficult because of fluctuations in currency values through floating exchange rates, and some attempt to standardize for this using
purchasing power parities, derived from data on the costs of a 'standard basket' of goods and services. In addition, as a recent OECD (2006) report indicated, comparison of GDP levels internationally is difficult because: it takes no account of leisure time and the quality of the environment; it is not standardized for income inequality (an extra $1,000 per annum means much more to a poor than to a rich person); it does not factor in negative contributors to the QUALITY of LIFE (such as POLLUTION); and it takes no account of the depreciation of capital stock. Unfortunately, though measures have been devised to capture these, they are not readily available for many countries.

**gross national product (GNP)** A measure of economic activity in a given period of time, usually applied to national economies. It comprises GROSS DOMESTIC PRODUCT (GDP) plus the net return from profits, dividends and income earned abroad. GNP estimates are used to compare the volume of economic activity over time and space – either in aggregate or per capita – but to avoid complications introduced by inflation and exchange rate fluctuations they have to be converted to a common base. This involves the use of purchasing power parities (the costs of a ‘standard basket’ of goods and services at a given period) – as in the calculated rate of inflation within a country, which is taken into account when calculating a ‘real terms’ rate of GNP growth. GNP is not necessarily a valid measure of ‘economic health’ since harmful consequences (e.g. on the environment) are not taken into account, whereas the later costs of their amelioration are: increased expenditure on POLICING could stimulate GNP growth, for example, even if it was merely a response to an increased CRIME rate.

**growth coalitions** Alliances of urban elites, with shared interests in local ECONOMIC GROWTH, partnered in pursuit of business-friendly and market-oriented forms of city GOVERNANCE and RESOURCE allocation (Logan and Molotch, 1987). Typically centring on the rentier CLASS (including developers, financiers and realtors), the business interests of whom are ‘place-based’, growth coalitions also comprise a range of auxiliary players such as universities, media and utility owners, representatives of business and civic organizations, cultural leaders and labour unions. What are sometimes called ‘growth machines’ or ‘urban regimes’ have assumed increased significance in the context of the entrepreneurial turn in urban politics since the 1970s. JPe

**growth pole** A dynamic and highly integrated set of industries, often induced by the state, organized around a propulsive leading sector or industry. Growth poles are intended to generate rapid growth, and to disseminate this through spillover and MULTIPLIER effects in the rest of the ECONOMY. The concept was devised by French economist François Perroux (1903–87), who, in 1955, located the **pole de croissance** in abstract economic space. It was translated into more concrete geographical terms by J.R. Boudeville (1966). On the bases of EXTERNAL ECONOMIES and economies of AGGLOMERATION – and hence of UNEVEN DEVELOPMENT – Boudeville argued that the set of industries forming the growth pole might be clustered spatially and linked to an existing urban area. He also pointed to the regionally differentiated growth that such a spatial strategy might generate. The precise meaning of the term ‘growth pole’ is difficult to pin down, however, because it is frequently used in a far looser fashion to denote any (planned) spatial clustering of economic activity.

The apparent simplicity of the notion, its suggestion of dynamism and its ability to connect problems of sectoral growth and planning with those of intra- and inter-regional growth and planning, led to its ready acceptance and widespread use in the 1970s and 1980s. Although some commentators have seen Perroux’s ideas resurfacing in the NEW ECONOMIC GEOGRAPHY (Meadon, 2001), there were several persistent difficulties associated with growth poles in both theory and practice that led to its fall from grace. These included the following:

1) **Technical problems**, notably: (a) the interdependent decisions to be made on the location, size and sectoral composition of a growth pole – this was not a serious problem for Perroux, who defined growth poles around a single propulsive industry, but more recent research on the related ideas of CLUSTERS and INDUSTRIAL DISTRICTS identifies NETWORKS of industries as central to urban and regional development; (b) the distinction between spontaneous and planned poles, with the latter requiring integrated social and physical

growth theory In the wake of the Second World War, and after the experience of the Marshall Plan in assisting the recovery of war-torn Europe, several economists with direct experience in multinational institutions and the Marshall Plan turned their attention to the question of economic development in the third world. Among these pioneers of development thinking were Finnish economist Ragnar Nurkse (1953), Austrian economist Paul Rodenstein-Rodan (1976), German-born and American-nationalized economist Albert Hirschmann (1958), West Indian Nobel Laureate Sir Arthur Lewis (1984), and American economic historian Walt Rostow (1960). Their ideas were far from identical, but they formed a loose school of thought — growth theorists — emphasizing a historically informed and practical approach to economic development, and stood at an angle to the neo-classical models of Solow and others. Rostow was something of an odd man out insofar as his simple stage theory of European industrial replication was both less analytical and less historically sophisticated than the others (cf. Rostow model).

The growth theorists were framed by three historical dynamics: the legacy of the Keynesian revolution and the experience of international Keynesianism through the European recovery programme; the political agenda of the USA in the wake of 1945 and increasingly during the cold war, which turned on the use of Bretton Woods institutions to foster development and fair dealing, as President Truman put it in 1949; and the nationalist developmentalism (cf. Nationalism) associated with the last wave of decolonization, which also emerged during and after the Second World War. Growth theory in its emphasis on aggregate phenomena and on industrialization bred a predilection for authoritative intervention — in which the state was a necessary actor — which involved planning systems, the application of economic growth models and aid mechanisms.

All of the growth theorists shared some sort of affinity for Keynes. They emphasized aggregate economic processes such as rates of saving and rates of investment (cf. neoclassical economics). Poor economic performance and lack of aggregate demand were related. They also revealed a preference for industrialization as a driving force — indeed, they were advocates of what in the 1930s had become import-substituting industrialization — and for short-term state interventions. Markets were means not ends, and like Alexander Gerschenkron (1968 — one of their contemporaries), they realized that late developers required a dirigiste state. However, as growth theorists they presumed that an economy would achieve its best results within a competitive market structure.

Each of the growth theorists is a major intellectual figure in the history of economics, but there were important commonalities and points of confluence (if not necessarily agreement), which animated their policy and theory during the 1950s.

There was the concept of hidden development potential in the less developed nations. As Gerschenkron had argued, there were ‘advantages to backwardness’, and in these advantages lay hidden comparative advantages:

- A recognition of market failures and the role of positive externalities in creating virtuous circle effects. Rodenstein-Rodan’s (1976) emphasis on social overhead capital and the role of government was a case in point.
• The *differences and merits of balanced and unbalanced growth*, and how each was related to the necessity for a ‘big push’ to trigger economic growth. Nurkse (1953), like Rodenstein-Rodan, emphasized the need for coordinated increase in the amount of capital utilized in a wide range of industries if industrialization was to be achieved. Hirschmann (1958), while agreeing with Nurske and others, also argued that unbalanced growth could, through linkage effects, generate innovations created by market responses to shortage and surpluses.

• The potential, as Lewis (1984) indicated, for *surplus labour as a stimulant to growth* in so-called dual economies.

• The *significance of saving* at particular historical moments in order to enter what Rostow (Rostow) called the ‘take-off stage’ of industrialization.

Growth theory, from the vantage point of the neo-liberal revolution of the 1980s, appears as an instance of Keynesian internationalism in which market failures, planning, social capital and some aspects of political economy are put to the service of ‘developing’ the poorer nations of the world. All of these growth theorists identified key developmental issues – equilibrium, social overhead capital, planning – which have continued to be objects of debate, and each (perhaps with the exception of Rostow) contributed to both the building of postwar multilateral development institutions and to the idea, which in a way was crushed by the weight of the Cold War, of a sort of liberal developmental internationalism (see liberalism). In the 1980s, a ‘new growth theory’ emerged in which endogenous growth can occur especially through human capital and new technologies (rather than being assumed, as in neo-classical approaches, by an exogenous savings rate or rate of progress of technical change).

Cypher and Dietz (1997); Preston (1996).
**habitus** A term coined by French anthropologist/sociologist Pierre Bourdieu to convey the routinized, yet indeterminate, nature of social practice. It mediates between objectivist accounts, such as from **structuralism**, and individualistic accounts, such as from **phenomenology**. The former would see individual practice as determined by social factors, while the latter would emphasize the individual’s intentions. In essence, then, it speaks to the oxymoronic nature of always improvised yet repetitively predictable practices of everyday life. Bourdieu himself defined habitus as the system of:

durable, transposable dispositions, structured structures predisposed to function as structuring structures, that is as principles which generate and organize practices and representations that can be objectively adapted to their outcomes without presupposing a conscious aiming at ends or an express mastery of the operations necessary in order to attain them. Objectively ‘regular’ and ‘regulated’ without being in any way the product of obedience to rules, they can be collectively orchestrated without being the product of the organizing action of a conductor. (Bourdieu, 1990b, p. 53)

This definition, then, emphasizes that practices are not (generally) subject to the anarchy of individual intentions. He plays down the role of intention, rejecting conscious planning as a principle, in favour of routinization. He also stresses that there are collective patterns without implying there is a conscious plan or conformity.

Rather, there is adaptation to a constricted set of opportunities presented to each actor in a ‘social field’. These have been variously interpreted, but usually represent a social domain in which there are shared rules of operation. These can be defined by institutions but can be more open, and are defined by the circulation of specific forms and practices. Bourdieu himself worked with the ‘artistic field’, or what he more broadly defined as the field of cultural production, the field of consumption and the ‘educational field’. Clearly, a critique is that the edges of these can be vague and that applied mechanically they merely render a institutional sociology. However, the virtue of his approach is that these fields are relatively autonomous from each other – thus advantage in one field does not automatically mean advantage in another. Most famously, he thus developed a notion of the accumulation of **cultural capital** as separate from **economic capital**. The plurality of fields provides for multiple dimensions of **power** and status in society. Each field has its own tacit rules and continual adaptation produces ingrained dispositions. For example, in Bourdieu’s study of amateur photography – a voluntary activity, in which few people have any training – he found people’s pictures remarkably similar, so ‘there are few activities which are so stereotyped and less abandoned to the anarchy of individual intentions’ (Bourdieu, 1990a, p. 19). Bourdieu has been criticized for being reductive and emphasizing the structural side of practices, and his work has an unfashionable belief in the ability to objectify the conditions of the emergence of practices.

Within **geography**, his work was first taken up as a way of mediating in debates between structuralism’s focus on determinations of action and accounts focusing on human agency (e.g. Thrift, 1983). Along with **structuration theory**, it offered a middle way in debates of the 1980s. In the 1990s, his work on cultural capital was heavily invoked in studies of consumption, connecting habitus to the lifestyles of different class fractions (e.g. Bridge, 2001). Finally, from the 1990s interest in his notion of habitus has focused around how tacit knowledge might connect with work on the body and routinized habit, and embodied memory (e.g. Alsmark, 1996).

**hazard** An event or phenomenon that does harm to human lives. Today, most researchers view hazards as the joint product of risk (the potentiality or probability of harmful events) and vulnerability (the degree to which risk-affected populations are likely to suffer from the event occurring) (Mitchell, 2003b, p. 17). The field of hazard research opened up in...
HAZARD

response to so-called ‘natural disasters’ – the suffering visited upon human populations by such extreme geophysical phenomena as floods, earthquakes and hurricanes (see also ENVIRONMENTAL HAZARD). These events remain core concerns. The prominence of physical forces as causes or triggers of human suffering points to the need for input from both the human and natural sciences, which would seem to present special opportunities for the discipline of GEOGRAPHY, with its constitutive concern with both social and physical processes. However, the various twists and turns in the development of hazard research thus far should caution against any sense that the field offers a straightforward or self-evident bridge between the study of the social and the natural, within geography or more generally. This is all the more so considering that the study of hazards increasingly concerns itself with more obviously human-induced harms, such as technological accidents, WAR, TERRORISM and social VIOLENCE.

Within HUMAN GEOGRAPHY, the crystallizing of a concern with hazards is usually traced to the mid-twentieth century work on floods in the USA by Gilbert White. In what became known as the HUMAN ECOLOGY tradition, White and his collaborators sought to provide an alternative to the ENVIRONMENTAL DETERMINISM of the late nineteenth and early twentieth centuries, by exploring the range of ways in which individuals or COMMUNITIES could construe and respond to hazards in their environment. However, later critics found the human ecology approach overly managerialist or technocratic – too concerned with adjustment or ADAPTATION of human populations to hazards, and not concerned enough with the social processes that rendered people vulnerable to hazards (Pelling, 2001; Mustafa, 2005).

The late 1970s and 1980s saw the rise of a perspective on hazards that viewed vulnerability as having at least as much to do with the conditions of everyday social life as with the specific physical events on which the human ecologists focused. This turn was signalled by the work of Amartya Sen (1981) and Kenneth Hewitt (1983), and further developed by input from the tradition of POLITICAL ECONOMY. Addressing issues at both local and global scales, the political–economic perspective draws attention to the ways in which socio-economic marginalization and powerlessness leaves some people living and working in conditions of vulnerability to hazard that the more privil-
to lose our bearings, it disturbs and destabilizes, he argued, precisely because it exceeds our experience or comprehension of the world.

Viewed in this way, accounting for the disastrous dimensions of hazards calls for something more than simply the extension of our rational understanding of causes and consequences. It invites us to contemplate the limits of our knowledge and how we might respond intellectually, politically and ethically, to such limits. The terrorist attacks of 11 September 2001 prompted Judith Butler to reconsider the precariously human life, and to muse on ‘the emergence and vanishing of the human at the limits of what we can know’ (2004, p. 151). For her, such a disaster impels us to reassess the way we address others who have suffered, and to think deeply about the role of loss and mourning in modern life (see ETHICS). This is not to make light of the achievements of apprehending hazard as socially constructed, but it is a reminder to think also about the capacity of hazards to shape and define our human condition, and to raise questions about the limits of knowing, writing about and ordering the volatile worlds that we inhabit.

Health and health care ‘The concept of “health” is open to differing interpretations’ (Curtis, 2004, p. 2). It can mean ‘the presence or absence of diagnosed diseases’, but also many different dimensions potentially contributing to the corporeal, emotional and social well-being of people in their everyday lives. Gesler and Kearns (2002, pp. 30–2) discuss ‘cultures of health’, identifying the explanatory models deployed by different people (e.g. experts contra lay people) and drawing inspiration from ‘ethnomedicine’ as the study of how such MODELS (and their deeper cultural, religious, cosmological moorings) vary from place to place. Additionally, assumptions about health clearly vary within places according to CLASS, ETHNICITY, GENDER and other markers of social difference (Lewis, Dyck and McLafferty, 2001).

Acknowledging such variability in health beliefs suggests an approach to a GEOGRAPHY of health that squares with recent shifts in the sub-discipline of MEDICAL GEOGRAPHY. Indeed, some argue that medical geography should be widened to include not just health defined through the lenses of Western biomedicine, casting health in the negative sense of not being physically or mentally ‘ill’, but rather in the broader sense indicated above, of health as well-being. This orientation demands a holistic focus on the great variability of the human condition, commonly at the scale of populations within territories, but in principle also at that of individual people interacting with quite specific sites. One upshot is then the enlarging of what is meant by RISK, with geographers addressing the many risks to health that people face from infectious illnesses but also from the likes of ENVIRONMENTAL HAZARDS, interpersonal VIOLENCE and occupational stress, all of which constitute multiple ‘spaces of risk’ figuring in domains of human DECISION-MAKING from the STATE to the HOUSEHOLD (Curtis, 2004, pp. 5–9).

A link exists here to a long-standing geographical concern for human well-being, sometimes configured as QUALITY OF LIFE, in which a political commitment to uncovering spatial injustice is never far below the surface. This concern awakened in the 1970s with the contribution of WELFARE GEOGRAPHY, and has continued into more recent work on the socio-spatial constitution of ‘health inequalities’. A key development has been Gesler’s (1992) notion of ‘therapeutic LANDSCAPES’, highlighting how places in all of their complexity can foster people’s senses of healthful well-being, and Curtis (2004, ch. 2) mobilizes this notion when fashioning new perspectives on the meeting-grounds of ‘health and inequality’.

Another link exists to the various currents now coalescing under the heading of EMOTIONAL GEOGRAPHIES, wherein varying human mind–body ASSEMBLAGES (see also Butler and Parr, 1999) are examined for how they are constituted, enacted, experienced, re-presented and perhaps politicized in relation to diverse SPACES, PLACES, environments and landscapes. Work in this vein asks about what might comprise places conducive to, or alternatively destructive of, ‘emotional health’.

These new trajectories complicate what is meant by health care, since such care can no longer be envisaged solely as providing medical facilities of varying kinds (hospitals, clinics, GP surgeries or even conventional medical outreach and educational services). Geographers have long studied these medical facilities (see MEDICAL GEOGRAPHY), but they have now begun to consider less overtly medicalized versions of care (Parr, 2003) – elder, hospice and terminal care (Brown, 2003); complementary and alternative medicines

HEARTLAND

Many core regions are referred to as heartlands. For example, the Midwest of the USA is often termed ‘the Heartland’, with the implication that it is not only central in a geographical sense but also foundational in a normative sense, the place where the core American values that come from the FRONTIER process are to be found (cf. HOMELAND).

The most important use of the term, however, was by British geographer Halford Mackinder (1861–1947). Mackinder argued against the late-nineteenth-century belief that sea-power was the basis for global supremacy. Mackinder (1904) suggested that the RESOURCES of a secure land-power could now be moved around more easily with the development of transcontinental railways. Further, he proposed that the largest basket of resources of what he termed the ‘World Island’ (EUROPE, ASIA, AFRICA) lay in Eastern Europe and western Russia. The core of this region was inaccessible by ocean-going navies. Gunboat diplomacy was ineffective against it. Were Russia, Germany or an alliance of the two to prevail in this region, they could mobilize resources that would make them invincible rulers of the World Island and almost certainly ultimate rulers of a World EMPIRE. Thus, Mackinder’s advice to the leaders drawing up a political map of Europe after the First World War was: ‘Who rules East Europe commands the Heartland: Who rules the Heartland commands the World-Island: Who commands the World-Island commands the World’ (1919, p. 194). From this followed two main strategic priorities: first, to separate the Soviet Union and Germany with a viable network of buffer STATES and, second, to prevent the Soviet - Union acquiring the string of warm-water ports that would enable it to extend its land-power on to the ocean-ways of the world. The first of these was close to the state-building that was attempted from the ruins of the empires of Eastern Europe after the First World War. The second of these was close to the policies of Soviet containment that animated the COLD WAR after the Second World War.

There have been many evaluations of Mackinder’s ideas. A favourable review that emphasizes Mackinder’s prescience is provided by Parker (1982), while more critical reviews of the central concepts of RACE, SPACE and history used in Mackinder’s GEOPOLITICS are provided by Agnew (2003a) and Kearns (2006a; see also Kearns, 2009). Advocates of the heartland thesis believe that it expresses more or less timeless relations between resources, space and military strategy. Critics argue: that in modern WAR, land- and sea-power have ceased to be distinct modalities; that far from being impregnable, the heartland has actually been occupied by hostile forces more than once in recent history (by the French under Napoleon, and the Germans under Hitler); that forceful relations between states do not exhaust the forms of INTERNATIONAL RELATIONS and that ignoring peaceful co-operation and multilateral institutions in fact makes the resort to force more likely by presenting it as inevitable; and, finally, that as technology changes, new resources will be valued and the geography of the competition for resources will shift. Despite these criticisms, our present hydrocarbon economy seems destined to focus attention for some time to come on parts of Mackinder’s heartland, with the Caspian Basin still vital in the RESOURCE WARS between the world’s Great Powers.

It is clear, then, that Mackinder’s heartland thesis has been very heavily cited and must

rank as one of the most significant geographical theories of the twentieth century. It has been claimed as central by various nationalists and imperialists, from Nazi Germany to modern Russia and the United States.

**Suggested readings**
Kearns (1993); Mackinder (1919).

**hegemony** The capacity to exercise control by means other than coercive force; namely, through constructing a willing mass acquiescence towards, and participation in, social projects that are beneficial only to an elite. Hegemony is the dissemination of the values and cultural practices of the elite in such a way that they become unquestioned. Thus, in everyday life the beliefs and values of the elite are reinforced, and a hierarchical social order is reinforced by the everyday actions (see EVERYDAY LIFE) of those who benefit less, if at all, from its existence.

Contemporary usage of the term is derived from the writings of Italian Marxist Antonio Gramsci (Gramsci, 1971 [1929–35]) who, while imprisoned by the Italian fascist regime between 1928 and 1935, reflected upon how the majority of citizens gave support to a repressive social order. The Frankfurt School of Marxism described how the post-1945 consumer culture was a form of hegemony, entrapping the working class in the pursuit of material possessions rather than social change. Cultural geographers have used these Marxist foundations to explore the role of landscape and place in perpetuating particular hegemonic ideals (Martin, 2000a: see CULTURAL GEOGRAPHY). Such works have extended the Marxists’ original concentration upon class relations to questions of race and patriarchy.

Particular attention has been paid to the practice of hegemony in colonial settings, especially how the landscape was used to inculcate ideals of racial hierarchy (McKinnon, 2005).

The term ‘hegemony’ has been utilized in a complementary fashion in the analysis of inter-state politics in POLITICAL GEOGRAPHY, though with the same roots and general meaning. A hegemonic power is the single most powerful state in the inter-state system. Though originally conceived in terms of material power (productive capacity and military might), scholars increasingly looked to the integrative power of the hegemonic state, or its ability to set a global agenda that, on the whole, other states followed. Post-1945, the USA was identified as the contemporary hegemonic state. Its material power is complemented by its dissemination of a ‘prime MODERNITY’ (Taylor, 1999), or the definition of the ultimate modern way of life. Connecting back to the Frankfurt School, the US ‘prime modernity’ is the consumer culture epitomized in its suburban lifestyle. Hegemony is maintained by other states’ desire to emulate this lifestyle and perceiving the adoption of particular economic and political practices as the means.

Hegemony, in both senses, is a process. Hence, discussion has arisen of the way hegemony is resisted. In the first meaning of the term, working-class and subaltern groups have adopted cultural practices that run counter to hegemonic demands. In the second meaning, discussion of the decline of US power, the challenge of other states and terrorist groups, and the meaning of ‘EMPIRE’ question whether hegemonic rule is being replaced by more coercive practices. A counter-argument is found in the notion of ‘imperial overstretch’ in which hegemonic states are eventually bankrupted by their overseas commitments and lose their primacy (Kennedy, 1988).

**heritage** Although ‘heritage’ includes and derives from a highly individualized notion of personal inheritance or bequest (e.g. through family wills and legacies), HUMAN GEOGRAPHY is concerned with collective notions of heritage that link a group to a shared inheritance. In this context, heritage usually denotes two related sets of meanings. On the one hand, it refers to iconic CULTURAL LANDSCAPES or, usually and more specifically, to TOURISM sites with an historical theme that have often been protected or preserved in some way for the nation-state and become part of the ‘heritage industry’; for example, a museum or an archaeological site (Urry, 2002 [1990]). On the other hand, heritage refers to a suite of shared cultural VALUES and MEMORIES inherited over time and expressed through a variety of cultural PERFORMANCES – for example, song or parade (Peckham, 2003). The basis of this group identification varies across time and space and can hinge on allegiance derived from, for instance, a communal religious tradition, a class formation, geographical propriety, and a national or imperial identity (Moore and Whelan, 2007).

Traditionally, historians and geographers have viewed heritage sites as spaces for inscribing nationalist narratives of the past on to the
Hermeneutics The study of interpretation and meaning. Hermeneutics derives from the Greek word meaning to announce, to clarify or to reveal. In this sense, hermeneutics has always been an integral part of the use of language. The first stirrings of hermeneutics as a formal discipline began with the elucidation of biblical texts: both clarifying God’s word, and adjudicating among competing interpretations. By the end of the eighteenth century, with the work of F. Schleiermacher (1768–1834), hermeneutics broadened to include the interpretation of historical texts more generally. In claiming that to understand a text required scrutiny of the intentions of its author, Schleiermacher’s hermeneutics implicitly challenged the relevance of the emerging scientific method for the human sciences.

Wilhelm Dilthey’s (1833–1911) writings both generalized hermeneutics and made its critique of natural science explicit. He argued that the human sciences (Geisteswissenschaften) required a special methodology, hermeneutics, in order to understand the meanings of its objects of study. Those certainly included texts, but under Dilthey’s view they could include any entity in which human meaning was invested. In contrast, the natural sciences (Naturwissenschaften) were not concerned with human meaning, and consequently applied an abstract universal vocabulary: the laws of physics, chemical formulae and geometrical relations.

For Dilthey, meaning is recovered through practicing the hermeneutic circle. By tacking back and forth both between our presuppositions and the text itself, as well as between individual parts of the text and its whole, meaning and understanding are attained. This same procedure can be used to clarify meaning in the non-textual, such as works of art, the artefacts of material culture or cultural landscapes. More generally, the hermeneutic method is intrinsically circular, indeterminate and perspectival. It is circular because it involves a constant movement from us, the interpreter(s), to the interpreted and back again, thereby implying that every interpretation is itself reinterpreted. It is indeterminate because that loop of interpretation has no end. And it is perspectival because interpreters are embedded in their situations, making their knowledge partial and incomplete (cf. situated knowledge). None of this means that interpretation is merely personal whim and fancy. Interpretations are always made against a set of socially agreed upon canons and texts (albeit interpreted ones) that are publicly accessible.
In the twentieth century, the German philosopher Martin Heidegger (1889–1976) took Dilthey’s epistemological rendering of hermeneutics and transformed it into an ontological one, making its focus ‘being’ rather than ‘knowledge’ (cf. EPistemology; onTology). The details are complex, but the gist is that problems of understanding unfold from our ‘being in the world’. Just as the hermeneutic circle for Dilthey involved tacking between parts of a text and its whole, for Heidegger it involves a movement between an anticipatory pre-understanding, which comes from our ‘being-ness’, and our role as knowing subjects. Hans-Georg Gadamer (1900–2002) subsequently took Heidegger’s notion of pre-understanding and showed its relation to notions of prejudice, authority and tradition. Since the ENLIGHTENMENT, Gadamer argued, there has been prejudice against prejudice. For him, however, ‘pre-judgement’, or pre-judice, is what makes understanding possible. In particular, the prejudices of historical ‘traditions’ are vital; without immersion in traditions, there is no understanding. It is not that traditions are frozen and immutable: Gadamer’s point is that we can never escape traditions and the historical perspective that they bring. Historical understanding proceeds by a movement from our prejudices (traditions) to the historical totality and back, making understanding ‘an open and continuously renewed “fusion” of “historical horizons”’ (Thompson, 1996, p. 381).

Gadamer’s work, in turn, provoked two other formulations. First, the German critical theorist Jürgen Habermas (b. 1929) thought that Gadamer made humans too much the dupes of historical tradition. Consequently, he developed a CRITICAL THEORY OF SOCIETY by setting hermeneutics against quasi-transcendental forms of ‘communicative reason’ that in conjunction produce the possibility of emancipation and liberation. Second, American philosophers Richard Rorty (1931–2007) and Richard Bernstein, writing under the sign of neo-PRAGMATISM, were sceptical of Gadamer’s claim that hermeneutics was the method of the human sciences, but acknowledged its importance for the critique of GRAND THEORY and other forms of FOUNDATIONALISM (thus connecting hermeneutics to POST-STRUCTURALISM). Both Rorty and Bernstein upheld the pragmatist ideal of ‘conversation’, which they believed was another version of the hermeneutic circle, in this case, juxtaposing new evidence and ideas with existing and possibly incommensurate ones.

Hermeneutics was introduced to HUMAN GEOGRAPHY to contest the EMPIRICISM and POSITIVISM found in SPATIAL SCIENCE. Buttimer’s (1974) ‘dialogical approach’, which involved bringing together inside and outside views, was an important early contribution, as were Tuan’s (1971) reflexive approach to TOPOPHILIA (‘to know the world is to know oneself’) and Harrison and Livingstone’s (1980) ‘presuppositional approach’. These early forays were codified under HUMANISTIC GEOGRAPHY, which made human meaning and intentionality the very core of its concern. Since then, the explicit working out of the hermeneutical approach has become less important, although there have been some exceptions, such as Barnes’ (2001) invocation in his work on the CULTURAL TURN within ECONOMIC GEOGRAPHY and Livingstone’s (2002c) writings on a distinctly ‘tropical hermeneutics’ (see TROPICALITY). In addition, hermeneutics has been implicitly present in the burgeoning discussions about ONTOLOGY, especially those drawing upon Heidegger, and which in turn have seeped into debates around SPATIALITY. More generally, the spirit of hermeneutical enquiry – that is, the recognition of the importance of interpretation, open-mindedness and a judicious, reflexive sensibility – is as great as it has ever been, and is certainly evident in CRITICAL HUMAN GEOGRAPHY, including those versions informed by POST-STRUCTURALISM.

heteronormativity
A social regulatory framework that produces binary sex division, normalizes desire between men and women, and marginalizes other sexualities as different and deviant. Much like WHITENESS, heteronormativity is naturalized so as to be invisible to the heterosexual population, but is a compulsory norm that itself produces NATURE; namely, BODIES sexed as male or female. Reversing the assumed relations between sex and GENDER, Butler (1990) has argued that heteronormativity is the foundation on which sexual difference is built. Predicated on the paternal law of kinship, heteronormativity ‘requires conformity to its own notions of “nature” and gains its legitimacy through the binary and asymmetrical naturalization of bodies’ (Butler, 1990, p. 106: see PERFORMATIVITY). Bodies outside this binary are unintelligible or monstrous. Berlant has argued that in the USA in the past 20 years, the
HETEROTOPIA

political has collapsed into the intimate sphere of the heterosexual family, such that ‘the family sphere [is] considered the moral, ethical, and the political horizon of national and political interest’ (1997, p. 262); this has led to the intensified regulation of heteronormativity. Honig (1998) cites the role of IMMIGRATION in reinforcing heteronormativity. Geographers have drawn attention to the many ways in which SPACE is bound up with the processes through which sexual identities are constructed, naturalized and contested, and to the need to study the particularity of heterosexualities in specific contexts (Hubbard, 2000). ‘Homonormativity’ has been identified as a new strand of heteronormativity. It is a politics that emerged in the 1990s, associated with state-sanctioned same-sex marriages and other rights for gays and lesbians, and it has been criticized for upholding, rather than contesting, dominant heteronormative assumptions and institutions. The GLOBALIZATION of this trend has led to criticisms of Western cultural IMPERIALISM; Oswin (2007) questions the geographical assumption that lies behind this critique – that of the DIFFUSION of ideas from Western to other societies – and argues for the need to assess the specificity of homonormativity in context. heterotopia Literally ‘another place’ or ‘place of otherness’, a term introduced into the HUMANITIES and social sciences by French thinker Michel Foucault (1926–84). Foucault borrowed the term from medicine, and uses it in opposition to utopia. While UTOPIAS – idealized happy places – do not really exist, but function as fantasies or spaces of hope, heterotopias for Foucault are places that do exist. But in their existing they radically undermine or challenge existing spatial orderings, they disturb, they are PLACES OF TRANSGRESSION OR OTHERNESS.

Foucault initially uses the term to describe linguistic or visual challenges, such as the writings of José Luis Borges or the paintings of René Magritte (Foucault, 1970 [1966], 1983). For Foucault these examples destroy ‘syntax’ – not just the syntax we use to make sentences, but also the syntax that constructs relations between words and things and allows classification and order. Borges’ fictional Chinese Encyclopaedia, with its outlandish categories, and Magritte’s shoes with toes, paintings that are part of the landscape that they portray and mirrors that reflect what they conceal, all disrupt and upset the commonplace. In a 1967 lecture, only published in French in 1984, shortly before his death (in English, see Foucault, 1986), Foucault broadened the analysis to include places he described as ‘counter-sites, kinds of effectively enacted utopias’. Although Foucault suggests that in the modern period space is characterized by the relation between sites generally, he concentrates on those sites that link with and contradict other sites. His examples include the boarding school or the honeymoon hotel, where transitions between stages of life are managed; care homes, hospitals and PRISONS, where deviation is placed; and a wealth of other examples, such as travelling fairgrounds, hammams, saunas, brothels, boats and colonies.

The term has been developed in a number of English-language writings in human geography and related fields (e.g. Marks, 1995; Soja 1996b). One of the most important and original analyses is found in the work of Hetherington (1997b), who understands heterotopias as ‘spaces of an alternative ordering’ that must be seen in relation to the sites they differ from. He uses this understanding, together with a number of historical readings of the Palais Royal, Masonic lodges and factories, to illustrate how MODERNITY is constituted through RESISTANCE and DIFFERENCE as much as through the process of ordering.

‘Heterotopia’ was also used by the French Marxist Henri Lefebvre (1901–91), but the meanings are not entirely congruent with Foucault (see, e.g., Lefebvre, 2003 [1970]). Lefebvre understood the city through the three terms of utopia, isotopia (the same place) and heterotopia (places that are other, other places, or places of the other). He uses these terms to understand the uniformity, difference, contradictions and dialectical relations of urban space. Indeed, Lefebvre thinks that urban space in the singular is restrictive, and needs to be understood as urban spaces, as the differentiated spaces and the spaces of difference found in the city (see also PRODUCTION OF SPACE).

heuristic A problem-solving procedure, which may be a set of formal rules (such as an algorithm) but more likely a pragmatic or ‘short-cut’ approach, such as drawing a diagram or reducing the set of all possible solutions to those that seem most probable. Many
heuristics involve ‘intelligent guesswork’ based on experience (as in games of chess) and can involve trial-and-error procedures, moving towards a ‘better’ solution (as with neural networks). Heuristics are often deployed in optimization studies – as with the travelling-salesman problem – and in various forms of classification (as in remote sensing). RJ

Hindutva This concept encapsulates the cultural justification for Hindu nationalism, a ‘Hinduness’ allegedly shared by all Hindus. Its first full articulation as a Hindu nationalist manifesto was made by Vinayak Damodar Savarkar in his 1923 work *Hindutva: Who is a Hindu?* For Savarkar, *Hindutva* was the life of a great race; it signified the religious, cultural and racial (‘blood’) identity of Hindus. He claimed that the membership of the Hindu nation depended upon an acceptance of India as both fatherland and holy land. The spatial strategies of *Hindutva*, aimed at rearticulating the link between the imagined community of Hindus and the sacred geography of its territorial domain (the nation-space), have had a significant impact on contemporary Indian society and politics.

hinterland The tributary (or catchment) area of a port, from which materials for export are collected and across which imports are distributed: its complementary area – the destination for the exports and source of the imports – is the foreland. In more general usage, hinterland is deployed to describe a settlement’s catchment area (or that of an establishment within the settlement): it is the area for which the settlement acts as a trading nexus (as in the hexagonal hinterlands of central place theory).

historical demography The application of demographic methods (see demography) to data sets from the past that are sufficiently accurate for formal analysis. Such data sets may take the form of vital records and censuses, but most frequently, and particularly if produced before the nineteenth century, would not have been created for the purposes of demographic enquiry. Parish registers, militia and tax lists, testamentary records and genealogies have been the most prominent among the great variety of documentary sources used by historical demographers (see Hollingworth, 1969). *Demographic history* may subsume historical demography as a field of enquiry, but it is more wide-ranging in its subject matter, being just as concerned with charting the impact of demographic change on society and economy as with the measurement and explanation of demographic change (see Wrigley, 1969).

Historical demography first secured a formal status in France at the Institut National d’Études Démographique (INED), where Louis Henry had begun research after the Second World War on contemporary fertility and fecundity. His investigations were handicapped because those states that produced the most accurate demographic statistics were by then all controlling their fertility by family limitation, and so he was drawn to the historical study of European populations to unravel ‘natural fertility’. Henry (1956) devised the technique of family reconstitution for exploiting genealogies of the Genevan bourgeoisie, and then developed detailed rules of family reconstitution using parish registers. The first published study concerned the Normandy parish of Crulai (Gautier and Henry, 1958), but the method was quickly adapted and modified for work on English parish registers by historical geographer and economic historian E.A. Wrigley (1966a). Wrigley (1966b) undertook a reconstitution of the East Devon parish of Colyton, where the population appeared to have been limiting its fertility in the late seventeenth century.

In the past thirty years, a large number of reconstitution studies have been completed and they have shown little, if any, evidence of parity-dependent fertility control, although the levels of fertility within marriage have varied enormously by region. For instance, marital fertility in Belgian Flanders was 40 per cent higher than that of eighteenth-century England, although the two regions were separated by only a few miles across the English Channel. Likewise, marital fertility was almost 50 per cent higher in Bavaria than in East Friesland. By measuring birth intervals and relating infant deaths to the time elapsed to new conceptions, family reconstitution has enabled historical demographers to show that breastfeeding practices varied greatly and thereby influenced the tempo of conceptions (see Wilson, 1982). Breastfeeding also correlated closely with infant mortality rates, which were also revealed by family reconstitutions to be very frequently in excess of 300 per 1,000 in non-breastfeeding areas and as modest, by pre-industrial standards, as 150 per 1,000 or lower in areas...
where women breast-fed well into the second year of the child’s life (see Knodel, 1988). Such techniques have also made it possible to cast light on the geography of marriage and to test an important thesis about the distinctiveness of marriage patterns in north-west Europe proposed by Hajnal (1965), who argued that females married uniquely late in life and that a large proportion remained entirely out of marriage. Hajnal discovered this pattern from census data of the nineteenth century, and family reconstitutions of France and England, southern Scandinavia and much of the German-speaking areas of Western and Central Europe showed this marital geography to have been firmly embedded before 1600 and hence not derived from URBANIZATION or INDUSTRIALIZATION, and common to both Protestant and Catholic areas (Smith, 1990).

The Cambridge Group for the History of Population was the first centre of research exclusively devoted to historical demography, and it developed techniques for the study of early censuses and aggregative counts of baptisms, burials and marriages to recreate demographic processes without employing the time-consuming method of family reconstitution. One such technique—generalized inverse projection—is a technique that projects back from a census providing accurate data on age structures and so making it possible to obtain age structures, population sizes, EMIGRATION rates, and measurements of fertility and life expectancy. This technique was first applied to English data and showed that fertility changes were considerably more important in determining demographic growth rates from c.1600, and to some extent endorsed the more optimistic view of Malthus as presented in the second edition of his Essay (Wrigley and Schofield, 1989 [1981]; see MALTHUSIAN MODEL). As research by historical demographers accumulated, it became apparent that eighteenth- and nineteenth-century European demographic patterns, even in the area of the so-called north-west European marriage and household formation systems, varied greatly (see Wrigley, 1981). Furthermore the extension of formal historical demographic enquiry to ASIA, utilizing early listings of inhabitants and population registers, has cast doubt on the assumed uniqueness of certain features frequently supposed to be peculiar to historic EUROPE (Lee and Feng, 1999).

**HISTORICAL GEOGRAPHY**

A sub-discipline of HUMAN GEOGRAPHY concerned with the geographies of the past and with the influence of the past in shaping the geographies of the present and the future. Before the twentieth century, the term 'historical geography' was used to describe at least three distinct intellectual endeavours: the recreation of the geographies described in the Bible and in ‘classical’ Greek and Roman narratives; the ‘geography behind history’ as revealed by the changing FRONTIERS and BORDERS of STATES and EMPIRES; and the history of EXPLORATION and discovery (Butlin, 1993, pp. 1–23). Fragmented and incoherent, these early writings had little impact on contemporary historical geography, whose intellectual roots can be traced to the late-nineteenth-century writings on regional landscape formation by French geographers such as Paul Vidal de la Blache (whose influence spread into Britain through the work of H.J. Fleure and A.J. Herbertson) and by the German school of ANTHROPOGEOGRAPHY led by Friedrich Ratzel (a perspective successfully promoted in the USA by Ellen Semple).

Historical research on LANDSCAPE change received a powerful stimulus after the First World War, when the reorganization of national boundaries in EUROPE and the creation of new ones in the MIDDLE EAST re-focused attention on regional landscapes as products of long-term economic, social and political evolution that could be analysed by the scientific interrogation of archaeological and historical evidence. The study of landscape change varied in different national contexts and was by no means always described by the term ‘historical geography’. Continental European research on regional, especially rural, landscape change continued without embracing a new disciplinary terminology. In inter-war France, the ANNALES SCHOOL produced a body of interdisciplinary research that might reasonably be described as historical geography, but that is more usually regarded as a distinctively French style of History. Likewise, in Germany, historical research on rural settlement change was generally seen as continuing an existing tradition of research on the CULTURAL LANDSCAPE rather than blazing a new trail in historical geography.

The situation was different in the UK, where the term ‘historical geography’ was deployed more frequently under the charismatic influence of H.C. Darby. Darby’s vision of historical geography exhibited many similarities with research carried out simultaneously on the history of the English
landscape by social and economic historians W.G. Hoskins and Maurice Beresford, but it was distinguished by its emphasis on cartography as a means to both interrogate and display the archive: by the use of historical sources to construct visually impressive and typically thematic maps. According to Darby, historical geography was a fundamentally geographical endeavour, one of the ‘twin pillars’ of the larger discipline, alongside geomorphology (Darby, 2002). Geomorphology and historical geography were both concerned with landscape formation and evolution, Darby argued, the former based primarily on field evidence derived directly from the natural environment and the latter on historical evidence gleaned indirectly from archival sources. Darby placed a special emphasis on the reconstruction of geographical patterns as cartographic cross-sections, exemplified by his seven-volume reconstruction of the human geography of medieval England, published with a series of collaborators and based on tabulations in the Domesday Book (Darby, 1977). He sought to link such cross-sections into larger sequences of landscape change (vertical themes), encapsulated in his work on the changing fenland landscapes of eastern England (Darby, 1940).

Darby’s version of historical geography spread to other parts of the English-speaking world, but the study of regional landscape change in the USA developed along distinctive lines under the influence of Carl Ortwin Sauer, doyen of the Berkeley School of Cultural Geography. Sauer wrote enthusiastically about historical geography, but his own work is more commonly described as cultural or cultural–historical geography, in accordance with his interest in anthropological and archaeological evidence, following in some part the German tradition of Landschaft research. In Sauer’s view, this was a more appropriate model for the study of long-term landscape change in the New World, where the scale of analysis was necessarily larger (so he claimed) and where written evidence was non-existent before European colonization. It is important to note, however, that some of the most successful ‘big-picture’ accounts of US history since Columbus have been written by American historical geographers working outside the Sauerian tradition (notably Earle, 2003; Meinig, 1986–2004), and that a number of historical geographers studying the interrelations between European conquest and native peoples have excavated archaeological and palaeo-environmental records and attended to oral traditions in ways that could not have been anticipated by Sauer.

The diffusion of spatial science in the 1960s and 1970s challenged many of the assumptions and practices of traditional historical geography, particularly the source-determined, cross-sectional studies that, through their disregard of social theory and their inattention to social process, seemed to have little purchase on the analysis of subsequent geographical structures. A lively debate ensued, some of it conducted in the pages of the *Journal of Historical Geography*, which was established in 1975. Several different kinds of historical enquiry emerged within human geography as a consequence of this period of rethinking and reformulation.

The first was advocated by those historical geographers who had become critical of their field’s source-bound empiricism, and who now welcomed a methodology that allowed historical data to be incorporated into more complex models of geographical change (Baker, 2003, pp. 37–71). The result was a more quantitative historical geography that had been anticipated by Torsten Hägerstrand’s early studies of diffusion and of ‘population archaeology’ that issued in his time-geography; both left enduring legacies (Pred, 1973; Dodgshon, 1998). Statistically minded historical geographers also became centrally involved in the field of historical demography, particularly in Britain, where E.A. Wrigley was a dominant influence (Wrigley and Schofield, 1989 [1981]). In Wrigley’s case, this involved an institutional move from geography to economic and social history, a well-trodden and often two-way career path. These interdisciplinary exchanges explain why some of the most important research on Britain’s agricultural history has been published by scholars trained as historical geographers (Campbell and Bartley, 2006; Overton, 1996: see also agricultural revolution; field systems). The significance of quantitative historical research within human geography is also attested by highly sophisticated studies of historical epidemiology and disease diffusion, consistently identified by their authors as historical geography (e.g. Smallman-Raynor and Cliff, 2004). The emerging field of historical geographical information science confirms the continuing strength of the enumerative tendency within historical geography (Gregory and Ell, 2007).

Other historical geographers, particularly those who had familiarized themselves with previously unexplored literatures in critical
HISTORICAL GEOGRAPHY

Theory and social theory, were less convinced by the claims made by spatial science. Some of the original advocates of a quantitative approach also shifted their position and ultimately rejected the philosophical assumptions derived from positivism that underwrote spatial science. From their perspective, statistical explanation lacked the capacity for ethical or political critique and failed to acknowledge human agency, intentionality and emotion (Harris, 1971; Gregory, 1981). Traditional forms of historical geography could scarcely claim a better track record, of course, so the solution was not to defend existing methods but, rather, to create a critical, theoretically informed historical geography within a new, historically sensitive human geography.

For some, this demanded a more direct engagement with historical materialism and a sustained analysis of the deeper economic, social and political forces determining geographical change, an approach that was strongly influenced by developments in social and economic history in general and the work of E.P. Thompson in particular (e.g. Gregory, 1982). The same concerns can be detected in other work on urbanization and the Industrial Revolution in Britain (Langton, 1979, 1984; Gregory, 1982; Dennis, 1984) and in more synoptic works such as Harvey’s extended (1985) essay on nineteenth-century Paris (see also Harvey, 2003a). Since the mid-1980s, new historical geographies of space, power and the social order have extended this style of historical research, inspired by other developments in social theory more critical of historical materialism, notably structuration theory, and a series of formulations that are conventionally identified as post-structuralism, notably the work of Michel Foucault (Driver, 1993; Ogborn, 1998; Hannah, 2000; Philo, 2004). Perhaps the most ambitious attempt to connect these diverse post-positivist thematics into an agenda for historical geography was Harris’ programmatic essay on modernity (Harris, 1991).

A somewhat different style of historical investigation arose from a second attack on spatial science. This sought to reconnect geography with a wider range of disciplines in the arts and humanities, based in part on hermeneutics. While sympathetic to historical forms of geographical enquiry, the leading advocates of a broadly humanistic geography refused to privilege the past as arena of investigation and therefore tended to define their work as (new) cultural geography allied to (comparative) literature, cultural studies and the visual arts rather than history. The cultural landscape has been the central preoccupation of this form of historical enquiry, which has generated a rich geographical literature, including several theoretically ambitious attempts to uncover the origins and development of landscape as social and political construction and as a way of envisioning and representing space, a project far removed from the way in which landscape was apprehended in traditional historical geography (Cosgrove, 1993; Cosgrove and Daniels, 1988; Duncan, 1990; Daniels, 1999). Investigations into the relationship between landscape, heritage and tourism generate continuing interest (Graham, Ashworth and Tunbridge, 2000), as does the relationship between landscape and memory (Johnson, 2003b), while research on twentieth-century debates about landscape, identity and social practice has been especially influential (Matless, 1998). There have also been important historical studies of cultures of travel and travel writing that pay close attention to the texts and the images that accompanied them (Schwartz and Ryan, 2003) and, moving historical geography still further from the seemingly obdurate physicality of landscapes, studies of ways in which the very technologies of writing were caught up in the transmission of power (Ogborn, 2007).

These distinct forms of historical research in geography, always closely related, have effectively merged in the past two decades (Graham and Nash, 1999; Withers and Ogborn, 2004). The single, hybrid term ‘cultural–historical geography’, originating in North America and in some measure a legacy of the Berkeley School, is now widely deployed to describe a different style of research in which three closely related themes have animated recent discussions. The study of imperialism and colonialism has grown steadily more important. This has shifted the focus of historical research in geography away from the global North, although the constellations of Euro-American Empire, hegemony and power continue to cast long shadows over many of these studies, in both their theoretical form and historical substance. This work has revealed how landscapes, identities and values in the core regions and in the colonized territories of Africa, the Americas and Asia were fashioned by a process of imperial interaction and transculturation involving the circulation of people and practices, objects and ideas on a global scale (Harris, 1997; Driver and Gilbert, 1999a; Clayton, 2000; Lester, 2001; Lambert,
2005; Legg, 2007b; Ogborn, 2007). These studies have involved a close and critical engagement with various forms of POST-COLONIALISM.

The colonial project was largely concerned with the acquisition and exploitation of NATURAL RESOURCES, and much of the new work on historical geographies of colonialism has focused on its environmental consequences. This is scarcely an unheralded development (Clark, 1949; Powell, 1988; Williams, 1989; Donkin, 1999), since the relationship between ENVIRONMENTAL HISTORY and historical geography has always been extremely close, particularly in the USA (Williams, 1994a). However, recent ENVIRONMENTALISM has generated a more politically charged historical geography that has explored the impact of natural resource exploitation on regional and urban development (Cronon, 1991), and which includes explicitly Marxist historical geographies on the interactions of CLASS, RACE and the physical environment in industrializing regions (Mitchell, 1996; Walker, 2001).

Western SCIENCE, including the science of geography, was directly implicated in the processes of agricultural and industrial transformation, urbanization and imperial expansion that historical geographers have increasingly investigated. This has prompted a renewed interest in the critical history of post-ENLIGHTENMENT geographical and environmental thought (Livingstone, 1992; Grove, 1995). Inspired in part by the writings of the literary critic Edward Said, this work has emphasized the constitutive significance of geographical knowledge in the creation of national and imperial IDENTITIES (Smith and Godlewska, 1994; Bell, Butlin and Heffernan, 1995; Driver, 2001a; Withers, 2001: see also ORIENTALISM). It has also reconnected historical geography with the history of cartography (see CARTOGRAPHY, HISTORY OF), particularly through the seminal work of historical geographer J. Brian Harley (Harley, 2001b).

No single methodological or philosophical orthodoxy has prevailed since the 1970s, and historical geography has become increasingly eclectic. This demonstrates the growing influence of perspectives from allied disciplines but is also evidence of a wider ‘historicization’ of human geography that has partially compromised historical geography’s status as a distinctive sub-discipline (Driver, 1988). This has generated some unease about sub-disciplinary identity, notably in the debate about the legitimacy of the terms ‘historical geography’ and ‘geographical history’ (Baker, 2007). But for all its thematic diversity, twenty-first-century historical geography has become increasingly focused on the (relatively) recent past, a trend partly determined by the need for reliable, spatially extensive data, but also influenced by the INSTRUMENTALIST assumption that historical research should have immediate relevance to contemporary issues (Jones, 2004b).

That said, its continued vigour is demonstrated in the pages of the Journal of Historical Geography and in the steady stream of innovative work in historical geography that also appears in the pages of mainstream journals inside and, crucially, outside geography. MH

Historical materialism The materialist conception of history, formulated by Karl Marx (1818–83) with Friedrich Engels (1820–95), and the ‘guiding thread’ of their joint work (see also MARXISM). Historical materialism is a theory of history incorporating a series of bold theses about the dynamics of historical change, most succinctly summarized in the 1859 ‘Preface’ to ‘A Contribution to the Critique of Political Economy’.

Social development is driven by progress in meeting social needs through the development of productive forces (means of production and labour power). In the process of production, men and women necessarily enter into certain social relations of production. These include both work relations (technical relations and forms of co-operation) and forms of ownership and control of the means of production, which are at the root of class formation. The totality of the relations of production constitutes the economic structure of society, ‘the real foundation, on which arises a legal and political superstructure and to which correspond definite forms of social consciousness’. The economic base and superstructure together constitute the mode of production of a society. (See also BASE AND SUPERSTRUCTURE.)

Each mode of production is subject to internal tensions and contradictions (see DIALECTIC). Thus, at a certain stage of their development, the material productive forces of society come into conflict with the dominant relations of production, which reflect entrenched forms of PROPERTY ownership and CLASS relations. The relations of production increasingly become fetters on the further development of the productive forces. ‘Then begins an era of social revolution’, transforming the economic structure, and with it the whole
immense superstructure, its institutions and forms of consciousness. In illustrating this theory of contradiction and change, Marx refers variably to the ancient, Asiatic, feudal and capitalist modes of production.

The theory outlined in the 1859 Preface appears disarmingly simple, and has tended to be downplayed by Marxists who find it too close to a form of economic, or even technological, determinism. Nevertheless, Cohen (1978) has shown how it can be given a rigorous and sophisticated modern defence if one is prepared to accept the validity of functionalist forms of explanation (see functionalism). Wright, Levine and Sober (1992) have also shown how the basic argument for economic primacy can be disaggregated into at least six linked sub-theses, not all of which are asserted with equal force in Marx’s many writings, and some of which are more defensible than others. It is thus possible to extract both ‘strong’ and ‘weak’ versions of historical materialism from Marx’s writings, with the latter placing more emphasis on the role of class conflict in social change, the role of the superstructure in shaping and reacting back on the economic base, and the role of contingent factors in opening up different historical trajectories.

Adding a spatial dimension to historical materialism brings further complexities. Giddens, for example, attempted to purge historical materialism of any evolutionary, functionalist, or reductionist tendencies, and his structuration theory incorporated spatial concepts such as ‘time-space edges’ and time-space distanciation into what he described as a weaker ‘anti-evolutionary, episodic model of social change’ (Giddens, 1981). However, the work of geographer David Harvey represents the most sustained and systematic attempt to incorporate space into a more general ‘historical–geographical materialism’ (see, centrally, Harvey, 1999 [1982]; also Castree and Gregory, 2006), and his study of nineteenth-century Paris demonstrates what can be achieved if such a framework is used subtly and flexibly as a guiding thread for research (Harvey, 2003a).

Historicism Historicism has two meanings: (i) intellectual traditions that assume human history to have an inner logic, overall design or direction (a ‘telos’); and (ii) critical traditions that insist on the importance of specific historical contexts to the interpretation of cultural texts and practices.

Historicism in the first sense invokes transhistorical forces to structure its explanations of human ‘progress’ (most visibly in the movement of the world-spirit, or Geist, in G.W.F. Hegel’s philosophical history). The appeal of teleology – of ‘unfolding’ models of social change – is now much diminished, and few scholars would see human history as predictable and susceptible to the formulation of universal scientific laws. When Karl Popper famously railed against the ‘poverty of historicism’ in this sense, he had a reading of Marxism as economic determinism in his sights, but subsequent versions of historical materialism have offered a much more open-ended view of human history and the spaces for political action (Popper, 1960 [1945]). The second sense of historicism is much more important to contemporary social enquiry. Historical context and historical specificity are articles of faith in historical geography, and while they were undermined by spatial science in the 1960s and 1970s, the emergence of a cultural–historical geography with a critical edge brought a closer, if largely tacit, engagement with a so-called ‘New Historicism’ – an approach to literary and cultural studies that originated in the USA in the 1980s (Gallagher and Greenblatt, 2001). Among the sources on which it draws, three are particularly important for human geography:

1. the thick description of anthropologist Clifford Geertz, which underwrites the importance of a close reading of minor events in such a way that they reveal the larger situations of which they are a part and to which they can be made to speak;
2. the genealogy of philosopher–historian Michel Foucault, which resists ‘power’s descriptions of itself’ by looking to the margins and the peripheries of situations; and
3. the cultural materialism of cultural critic Raymond Williams, which emphasizes the materiality of cultural formations and their contradictory constitution.

New Historicism has influenced studies of colonial discourse in post-colonialism and has much in common with work in cultural geography and the ‘contextual approach’ to the history of geography (see geography, history of). It should be noted that when Soja (1989, 1996b) objects to ‘historicism’, he has in mind an over-valuation of historical
holocaust  Most generally, the systematic deaths of large numbers of people, but most specifically the campaign of GENOCIDE pursued by Hitler’s Third Reich during the Second World War (1939–45) and identified by its initial capital: the Holocaust. Both usages depend on political and cultural processes of distinction and exclusion (see RACISM) and a studied indifference to the suffering of those construed as radically ‘Other’ (see BARE LIFE). Thus Thornton (1990) and Stannard (1992) connect EUROPEAN COLONIALISM to the mass destruction of indigenous societies in the AMERICAS, Davis (2002) identifies a series of late-nineteenth-century famines across the global South as a ‘cultural genocide’ brought about by the logics of imperial power and free trade, and all historians of the Nazi genocide acknowledge its roots in a racial fantasy of ‘Aryan’ supremacy and a profound anti-Semitism (see also FASCISM).

The Nazis did not confine their predations to Jews. They also systematically murdered millions of non-Jewish Soviet and Polish citizens, hundreds of thousands of Roma and Sinti (Gypsies), mentally and physically disabled people, gay men, religious dissidents and political opponents, including trades unionists, communists and socialists; the first concentration camp that the Nazis established at Dachau in 1933 was for political prisoners. But the (capitalized) Holocaust is increasingly and usually reserved for their concerted murder of approximately 6 million European Jews who died through malnutrition, medical experimentation and slave labour in concentration camps, who were shot or gassed by mobile killing units, or who were killed in gas chambers. This particular usage is problematic, however: in its original Greek form, ‘holocaust’ denoted sacrifice by fire, and while these spiritual connotations may resonate with the role Christianity played in legitimizing the deaths visited on indigenous peoples by European colonialism, their inappropriateness to describe the mass murder of European Jews has prompted many scholars to prefer the Hebrew Shoah (‘catastrophe’) (though this in turn may evoke the biblical sense of retribution found in the book of Isaiah).

Whichever term is preferred, Cole and Smith (1995, p. 30) identified the Nazi Holocaust as ‘the most remarkable blank-spot in geographical research’. It is strange that it should have attracted so little analytical attention, even by Israeli historical geographers, not merely because the Holocaust ‘had’ a geography – it was distributed over space and varied from place to place (Gilbert, 2009) – but more fundamentally because GEOGRAPHY as both discipline and knowledge was central to the project (Charlesworth, 1992):

(1) Particular conceptions of SPACE and spacing were indispensable to the conception of the Nazi Holocaust. Clark, Doel and McDonough (1996) identify two crucial spatial templates. The first was developed through a racist version of GEOPOLITIK that asserted the right to an expanded Lebensraum for the master-race, but such a project for ‘mastery of concrete, de-populated, physical space’ was inseparable from a second spacing, Entfernung: ‘an effective removal of the Jews from the life-world of the German race’ (Bauman, 1991, p. 120). To these three writers, Bauman’s cardinal contribution was ‘his recognition of the rupturing of the imaginary social space of the Reich by the diasporic space of the Jews’. The non-national space of the DIASPORA was ‘a wholly Other conception of social space’, they argue, a fundamental contradiction to the project of National Socialism and its territorial inscription of the ‘Aryan’ Same: in short, ‘a void’ (Clarke, Doel and McDonough, 1996, pp. 474–5; see also Doel and Clarke, 1998).

(2) The realization of Lebensraum and Entfernung entailed at once a de-territorialization of physical space and its re-territorialization as social space. This involved the conjoint production of a series of physical and social spaces (a) from which Jews were excluded, (b) within which they were gathered and sequestered, and (c) through which they were subsequently transported to the camps. These spatial strategies – which might be thought of as ‘a series of concentric circles that, like waves, incessantly wash up against a central non-place’ (Agamben, 1999, pp. 51–2) – produced a
vast genocidal archipelago (figure 1, page 339) and can in some measure be mapped on to Hilberg’s (2003 [1961]) four-stage model of the Holocaust: deprivation; expulsion; segregation; annihilation. Friedlander (1997, 2007) reworked these stages as follows (the examples given are illustrative, not exhaustive):

- **Persecution (1933–9):** the rights of German Jews were increasingly restricted, and in 1935 they were stripped of their citizenship; they were also subject to physical attacks and, from March 1938, many were imprisoned in concentration camps at Dachau, Sachsenhausen and Buchenwald.

- **Terror (autumn 1939 to summer 1941):** Polish Jews were confined to ghettos and subjected to extraordinary deprivation, and as the Reich expanded, the number of concentration camps multiplied and the use of forced labour intensified.

- **Mass murder (summer 1941 to summer 1942):** from October 1941, German Jews were deported to the occupied eastern territories; 33,700 Kiev Jews were shot in the Babi Yar ravine outside the city, and around 27,000 Jews were taken from the Riga ghetto and shot.

- **Shoah (summer 1942 to spring 1945):** in 1942, six concentration camps in occupied Poland – Auschwitz/Birkenau, Belzec, Chelmno, Majdanek, Sobibor and Treblinka – were designated as extermination camps, dedicated to the so-called ‘Final Solution’ of the ‘Jewish Question’, and gas chambers were used for mass killing: Jews throughout occupied Europe were arrested, deported to transit camps, and then sent to the extermination camps.

It is crucial to understand that these phases, and their correlative spaces, cannot be contained by a narrative of German policies and actions: as Friedlander (2007, p. xv) insists, ‘at each step in occupied Europe the execution of German measures depended on the submissiveness of political authorities, the assistance of local police forces or other auxiliaries, and the passivity or support of the population and mainly of the political and spiritual elites’.

(3) The planning and execution of the Holocaust thus relied on extensive geographical knowledge. The Reich Foundation for Geographical Studies was instrumental in the ethnic profiling and mapping of occupied territories, particularly in eastern Europe, while Walter Christaller, the architect of CENTRAL PLACE THEORY, was closely involved in developing the Generalplan Ost for the east of Poland. This vast region was under direct SS administration and was to be a laboratory for a new territorial order (figure 2, page 340): Germans were to ‘resettle’ the area, Poles reduced to slave labour, and Jews deported to the ghetto in Lodz and ultimately to the death camps (Rössler, 1989, 2001).

As the previous citations indicate, in recent years several geographers have concerned themselves with philosophical and historiographical issues surrounding the Nazi Holocaust, but there have also been substantive studies of the enforced production of Jewish ghettos (Cole and Smith, 1995; Cole, 2000) and of the role of landscape in the work of memory and memorialization (Charlesworth, 1994, 2004). All of these enquiries raise profound questions about representation and the capacity of language to render the experience of such extreme trauma (Friedlander, 1992; Agamben, 1999; LaCapra, 2000; Waxman, 2006). These have engaged the attention of geographers too, but the analysis of the Holocaust is necessarily both an interdisciplinary and a comparative project, and the United States Holocaust Memorial Museum publishes a journal dedicated to these issues: Holocaust and Genocide Studies.

The Nazi genocide continues to cast long shadows over the present. It has prompted politico-intellectual campaigns against both those who deny it and those who exploit it: to fight ‘for the integrity of the historical record’, as Finkelstein (2000, p. 8) puts it. The Holocaust materially affects political debates, policies and practices in Germany, Israel and the MIDDLE EAST. And it still troubles continental European PHILOSOPHY and SOCIAL THEORY, not least in their understandings of MODERNITY and the very possibility of critical enquiry. Indeed, Agamben (1998, 1999) sees the Nazi concentration camp as paradigmatic of political modernity:

Auschwitz is precisely the place in which the state of exception coincides perfectly with the rule and the extreme situation becomes the very paradigm of daily life … As long as the state of EXCEPTION and the normal situation
are kept separate in space and time, as is usually the case, both remain opaque, though they secretly instigate each other. But as soon as they show their complicity, as happens more and more often today, they illuminate each other . . . (Agamben, 1999, pp. 49–50)

Given the spatial foundations of this state of exception, the Nazi Holocaust should surely trouble geography too.

home An emotive place and spatial imaginary that encompasses lived experiences of everyday, domestic life alongside a wider
sense of being and belonging in the world. As a space of belonging and alienation, intimacy and violence, desire and fear, the home is invested with emotions, experiences, practices and relationships that lie at the heart of human life (see emotional geographies). Geographies of home span memory and nostalgia for the past, everyday life in the present, and future dreams and fears, and are imagined and materialized on scales from the domestic to the global (Blunt and Dowling, 2006). Through its internal intimacies and connections with the wider world, the home is ‘perhaps the most emotive of geographical
concepts, inextricable from that of self, family, nation, sense of place, and sense of responsibility toward those who share one’s place in the world’ (Duncan and Lambert, 2004, p. 395). Although home might take the material form of a house or other shelter, it extends far beyond a material dwelling, the household and the domestic. Rather than viewing the home as a private sphere that is separate from the public world of work, CITIZENSHIP and politics, a wide range of research in historical and contemporary contexts has explored the importance of paid and unpaid work within the home, the ways in which home-making practices are tied to ideas about citizenship, and the political significance of the home and DOMESTICITY (see DOMESTIC LABOUR; PRIVATE AND PUBLIC SPHERES).

The home has long been part of a GEOGRAPHICAL IMAGINATION, as shown by early research on CULTURAL HEARTS and the DIFFUSION of different house styles. More recently, humanistic, feminist and post-colonial geographers have been particularly influential in studying the home. Humanistic geographers have written eloquently about the home as a site of authentic meaning, value and experience, imbued with nostalgic memories and the love of place. In the 1970s and 1980s, humanistic geographers, in contrast to the abstractions of spatial science and inspired by the phenomenological work of Gaston Bachelard (1994 [1958]), described the home as a personal, intimate and poetical place. For Bachelard, ‘a home, even though its physical properties can be described to an extent, is not a physical entity but an orientation to the fundamental values ... with which a home, as an intimate space in the universe, is linked to human nature’ (Bunkšė, 2004, pp. 101–2; original emphasis). Humanistic geographers (including Bunkšė, 2004) continue to write evocative accounts of home that bind individual dwelling to the wider cosmos (see HUMANISTIC GEOGRAPHY). Other geographers have begun to study the home as a ‘more-than-human’ place, reflecting the entangled geographies and complex co-habitations of NATURE and CULTURE (including Kaika, 2004).

Feminist geographers have also been concerned with the relationships between the intimate relationships of home and the wider world, but in very different ways. Across a wide range of areas and contexts, feminist geographers have analysed the home as a gendered place, shaped by different and unequal relations of POWER, and as a place that might be dangerous, violent and unhappy rather than loving and secure (on home and feminist politics, see Young, 1997a). FEMINIST GEOGRAPHIES challenge the MASULINISM that either ignores the home or overlooks the power relations that exist within it. Inspired by the work of many black feminists who have rewritten home as a site of creativity, subjectivity and resistance (including hooks, 1991), such studies also challenge a white, liberal feminism that has understood the home primarily as a site of oppression for women. For socialist feminists, the home is a site of SOCIAL REPRODUCTION – for housing, feeding and nurturing workers – and is crucial for analysing the wider interdependence of CAPITALISM and PATRIARCHY. For those geographers drawn to POST-STRUCTURALISM and POST-COLONIALISM, the home is part of a wider spatial lexicon that has become important in theorizing IDENTITY, often closely tied to ideas about the politics of location and an attempt to situate both knowledge and identity (Pratt, 1997).

Post-colonial geographers have also explored the relationships between home, NATION and EMPIRE; the material and symbolic geographies of home and homeland; and the spatialities of home, dwelling and belonging in relation to indigeneity, settlement and DIASPORA (including Blunt, 2005). A central theme within this research is the home as a site of power and RESISTANCE, as shown by studies of imperial home-making, the importance of the home in anti-imperial nationalist politics, SOCIAL JUSTICE, belonging and the politics of home for indigenous people, and the contemporary politics of homeland (in)security. Rather than viewing the home as singular and static, a wide range of research on MIGRATION and diaspora unsettles notions of fixed roots and origins (including Ahmed, Castañeda, Fortier and Sheller, 2003), revealing multiple attachments and belongings that are materially manifested in home-making practices and MATERIAL CULTURES at home (Tolia-Kelly, 2004).

Reflecting the current vibrancy of geographical interest in the home, Blunt and Dowling (2006) have developed a critical geography of home, arguing that:

- Material and imaginative geographies of home are closely intertwined. “[H]ome is a relation between material and imaginative realms and processes, whereby physical location and materiality, feelings and ideas, are bound together and influence each other . . . Moreover, home is a process of creating and understanding forms of dwelling and
belonging. Home is lived as well as imagined. What home means and how it is materially manifest are continually created and re-created through everyday home-making practices, which are themselves tied to spatial imaginaries of home’ (p. 254). The materialities of home – including domestic architecture, interior design, material cultures and home-making practices – are themselves shaped by, and interpreted through, a wide range of ideas about home.

- **Home, power and identity are intimately linked.** ‘Home as a place and as a spatial imaginary helps to constitute identity, whereby people’s senses of themselves are related to and produced through lived and metaphorical experiences of home. These identities and homes are, in turn, produced and articulated through relations of power’ (p. 256). Rather than view the home as a fixed and bounded site, grounding and containing identity, geographers have unsettled both home and identity to reflect their mutual locatedness and porosity, rootedness and mobility. The home has become an important site for studying inclusions, exclusions and inequalities in terms of gender, class, age, sexuality and ‘race’.

- **Geographies of home are multi-scalar.** ‘Home is a socially constructed scale that extends beyond the house and household. . . . [T]he relations of domesticity, intimacy and belonging that construct home not only extend beyond, but also help to produce scales far beyond the household’ (p. 257; also see Marston, 2004a). Ideas and lived experiences of home are located within, travel across and help to produce scales from the body to the globe, as shown by the political significance of embodied domesticity in reproducing and resisting nations and empires; the bungalow and the high-rise as transnational domestic forms; migratory transformations of home; and the employment of domestic workers in the global economy (including Pratt, 2004).

A wide range of research across the humanities and social sciences interrogates normative ideas of home as a private, bounded, autonomous, safe and comfortable place. The emotive power of home is not only evident in feelings of attachment, belonging and familiarity and their material manifestations, but also in feelings and experiences of loss, alienation and exclusion, as shown by research on domestic violence, homelessness and displacement. The term domicile, for example, has been coined by Douglas Porteous and Sandra Smith (2001) to refer to ‘the deliberate destruction of home by human agency in pursuit of specified goals, which causes suffering to the victims’ (p. 12). Distinguishing between its ‘everyday’ forms – through, for example, urban redevelopment and economic restructuring – and its ‘extreme’ forms – including war and the forced resettlement of indigenous people – Porteous and Smith estimate that at least 30 million people across the world are victims of domicile (cf. urbicide). AB

**homeland** An area to which a people or a political community is closely attached. ‘Attachment’ has a profoundly cultural and political meaning in all major uses of the term. In much of European geography, ‘homeland’ carries resonances of the German *Heimat*, a spiritual, even mystical and often romanticized attachment to a native land, the place to which a person is tied by blood that is also the space of the Nation. In the first half of the twentieth century, ‘homeland’ in this sense became infused with ideologies of racial purity and patriotism in the veneration of the Fatherland that was central to the rise of fascism in general and the Third Reich in particular. For others, and particularly for the peoples of the diaspora, ‘homeland’ became an object of nostalgia, desire and identification, most viscerally so for those displaced and without a home of their own: hence, for example, the project of a ‘Jewish Homeland’ that gained momentum after the First World War and culminated in the formation of the State of Israel in 1948. In the 1960s and 1970s, the term was cynically invoked to secure the system of apartheid in South Africa through the creation of ‘black homelands’ (Transkei was the first). These were purely instrumental attempts to confine black Africans to scattered rural areas whose delimitation bore little relation to their own cultural geographies (Butler, Rotberg and Adams, 1977).

In American cultural geography, ‘homeland’ became a term of art in the second half of the twentieth century. It too implied an historically sedimented sense of identity that
derived from an intimate interaction between people and land (cf. CULTURAL LANDSCAPE), but it was invariably tied to the REGION rather than the national scale. Thus Nostrand (1992, p. 214) emphasized how inhabitants come to have 'emotional feelings of attachment, desires to possess, even compulsions to defend' their homeland. He was describing an Hispanic homeland, and cultural-historical geographers have identified other ethnically based homelands within the USA (Nostrand and Estaville, 2001). In the early twenty-first century, however, in the wake of 9/11, the USA revived the concept of homeland on a national (and nationalist) scale. The political-cultural affiliations of the term were intensified with the creation of a federal Department of Homeland Security in 2002. Its actions are directed towards BORDER SECURITY and the prevention of TERRORISM against the USA through advanced systems of SURVEILLANCE, profiling and the like, but it is also deeply invested in what Kaplan (2003) perceptively identifies as 'the cultural work of securing national borders'.

Kaplan (2003); Nostrand and Estaville (2001).

homelessness A complex social problem that, in the most basic terms, is defined by a lack of shelter in which to sleep and to perform basic activities such as bathing. The characteristics of homeless populations vary geographically. There are distinctions between the identities and experiences of homeless people in developed versus less developed countries, where service-dependent substance abusers sleeping rough would be an example of the former, while the latter would be exemplified by rural–urban migrants occupying squatter settlements (see SQUATTING). There are also variations in homelessness among countries, stemming from differences in national economies, welfare policies and so forth.

In developed countries, the diversity of the homeless people has increased markedly since the 1970s. For instance, middle-aged white males, who traditionally dominated homeless populations in North America, are now eclipsed numerically by ethnically diverse women, CHILDREN, and youth, including people with mental disabilities, substance abusers, victims of domestic VIOLENCE, and the elderly (Takahashi, 1996). While often regarded as largely an urban issue, homelessness among these groups is also increasing in rural areas (Cloke, Milbourne and Widdowfield, 2001). Finally, the break between being housed and being homeless is neither sharp nor definitive. Rather, homeless people may find themselves in a cycle, moving back and forth between the streets and shelters, after a prolonged decline from cheap rental housing, through living with friends or family, to shelters and the street. This sequence also hides many homeless people, contributing to difficulties in counting the population.

The causes of homelessness are a longstanding topic of debate. Takahashi (1996) suggests that geographers largely adhere to structural explanations, which focus on interconnections between increased levels of POVERTY and decreased availability of affordable shelter (Wolch and Dear, 1993). Specifically, this perspective identifies a combination of the following factors as crucial to the rise of homelessness in developed countries: economic change, leading to the expansion of low-paid, no-benefit, insecure service-sector jobs; the decline in WELFARE STATE benefits exacerbating economic problems, coupled with other policy shifts such as the deinstitutionalization of mental health services; demographic changes, including changing family structures, the feminization of poverty, and increases in the elderly population; and the reduced availability of affordable housing, in cities experiencing upward pressures on rents as a result of a BACK-TO-THE-CITY MOVEMENT and GENTRIFICATION, in suburban and rural areas where prices are also rising, and in the wider context of declining STATE provision of social housing. The structural perspective contradicts other explanations that suggest that individual failings and vulnerabilities (e.g. drug addiction, family instability) are the primary causes of homelessness.

Solutions and responses to homelessness and their implications for social life have been another focus for geographers. The PRIVATIZATION and reorganization of PUBLIC SERVICES has had a complex impact on the geographies of homeless people's lives, as some cycle through institutional settings (DeVerteuil, 2003). Also, public stigmatization of homeless people and increasingly harsh policy responses to their presence in PUBLIC SPACES (represented by anti-panhandling ordinances and 'bum-proof' benches) have spurred ongoing investigations and interventions into questions of homeless people's RIGHTS TO SPACE (Mitchell, 2003a).

homo sacer Literally both 'sacred man' and 'accursed man', homo sacer was a
subject-position conferred by archaic Roman law on those whose lives and deaths were deemed to be of no consequence. This dismal figure has come to be of considerable significance in contemporary political philosophy and human geography. People placed in this position could not be sacrificed (because they were outside divine law – their deaths were of no value to the gods) and they could be killed with impunity (because they were outside juridical law – their lives were of no value to their contemporaries). Agamben (1998) argues that homo sacer emerges at the point at which sovereign power suspends the law, whose absence falls over a zone of abandonment. The production of this space – the space of exception (see exception, space of) – is central to his account of modern biopolitics. Critics have dismissed Agamben’s retrieval of homo sacer as extravagant (Fitzpatrick, 2005) and even mythical – certainly Agamben does nothing to recover the wider cultural constructions of death in early Roman society, and the ways in which (for example) figures such as the gladiator were also exposed to death – but his purpose is not primarily historical or exegetical: it is, rather, to project homo sacer into the present as a cipher for bare life. Agamben does so in order to claim that sovereign power has so aggressively reasserted itself that the state of exception is increasingly becoming the rule and that, in consequence, we are all potentially homines sacri. These arguments have been important for debates around human rights and the very definition of ‘the human’, where geographers have insisted on the uneven and differential distribution of vulnerability: homo sacer is marked by class, gender, sexuality and ‘race’ (Gregory, 2004b; Sanchez, 2004; Pratt, 2005). These analyses also reveal the importance of the body: homo sacer is thus transformed from a metaphysical sign into a corporeal materialization of political violence.

Homophobia and heterosexism Though interrelated, these terms refer precisely to different exercises of oppression. Homophobia refers to the fear of lesbians and gays, the existence of ‘homosexuality’, and sometimes other dissident or non-normative sexualities, bodily performances or political struggles. The term is used diffusely around queer theory, however, to describe sentiments ranging from the disciplining, distancing, unease, disgust or hatred towards a queer other (who may be an embodied other or a dimension of the self: see abjection; psychoanalytic theory). By contrast, heterosexism (also called heteronormativity) refers to structures or agencies in society that privilege and normalize male–female sexual relations over same-sex (or queered) ones, as well as the gendered performances that accompany them (see performativity). The terms may refer to structural barriers, or to human agency, consciousness or subjectivity. Most if not all recent work across queer geography and sexuality-and-space studies explore, document or critique the panoply of forms that either homophobia or heterosexism can take.

There are at least two ways that geography is implicated in these terms. The first is that the topical interests of geographers, especially spatiality and nature–culture relations, are dimensions through which critical geographers are exposing and critiquing homophobia and heterosexism. For example, the popular spatial metaphor of ‘the closet’ to describe the concealment, denial, or erasure of gays and lesbians has been spatialized to show how homophobia and heterosexism work through spatial arrangements and practices (Brown, 2000). Scales of analyses have ranged from the body (how sexuality functions as a performatative, and its spatial situatedness affects performance), to the global (as in questions of international tourism, migration and refugees, and post-colonial legacies; e.g. Puur, 2002). Both place and movement can be assessed as heteronormative or homophobic.

The second way of conceiving the links between geography and homophobia involves the discipline’s long and under-exposed history of internal homophobia and heterosexism, which has certainly been associated with its masculinism. Yet the discipline has long been populated by lesbians, gays, bi- and omnisexuals, even transgendered and transsexual people, some in quite prominent positions, with stellar reputations. These geographers have often experienced damaging and painful repercussions because of their sexual identities or practices (e.g. homophobia was implicated in the closure of the Harvard geography department; see also Valentine, 2000). The widest array of charges of homophobia and heterosexism have been brought by Binnie (1997), who has detected strains, not simply in conventional positivist branches of the discipline, but also in allied critical areas such as Marxist geography and feminist geography.

**hot money** Portfolio capital investment that is both short-term and volatile in nature (Froot, O’Connell and Seasholes, 2001). Hot money accumulates rapidly in periods of economic boom, but dissipates quickly in times of crisis, which tends to exacerbate and intensify such crises. Portfolio capital investment is risk averse, and is directed mainly towards property and financial commodities, for which there are well developed secondary markets. These secondary markets expedite both the rapid entry and exit of money from an economy. The inflow and outflow of hot money has been associated with numerous financial crises since the beginning of the twentieth century, and recently with financial crises in South East Asia, Russia and Argentina.

**Hotelling model** A classic model of the location strategy deployed by firms seeking to maximize their market share through the size of their hinterlands. The original model produced by Harold Hotelling (1895–1973: see Hotelling, 1929) identified the strategies of two firms competing in a linear market, where customers were evenly distributed, and was generalized with the example of ice-cream sellers competing on a beach (Alonso, 1964b). As formulated, the model showed that, whatever their starting locations (e.g. figure 1), the two firms would converge at the centre of the beach (figure 2), from where each would serve the half of the customers closer to them than to their competitor: those furthest from the centre would pay more for the product because of the greater transport costs/time involved in making a purchase. The most efficient equilibrium distribution for two firms sharing the market equally would be that shown in figure 3, with each serving half of the beach and the total transport costs less than in figure 2. Each firm would realize, however, that if it moved closer to the centre it could capture customers from its competitor, hence the two providers congregate there.

Hotelling’s model has been used to account for patterns of agglomeration under certain circumstances, and has also been applied to other competitive situations, exemplified by the large literature on the ‘spatial theory of voting’ developed from Downs’ (1957) classic work (cf. Public Choice Theory).

**household** A socio-economic formation comprised of one or more individuals who share living quarters, often framed as those who ‘eat from the same bowl and live under one roof’. While this notion provides some latitude against the common assumption that the household is coterminous with family, whether nuclear or extended, it lacks the spatial robustness to encompass more expansive notions, including the increasingly common formation of transnational households. Wright and Ellis (2006) frame the household ‘simultaneously as a spatial scale and a set of practices; not situated in one place, but involving heterogeneous lives interacting with others all over town’, or further afield, as recent migration research suggests.

Considering the household as a spatial scale can illuminate its structural relations with other scales, and bring to the fore the interconnections
between production and social reproduction at its heart. This understanding provides a corrective for the common assumption that the household is a ‘natural’ unit; a perspective that allows it to be disregarded in economic analyses, its substantial contributions to local and national economies ignored or taken for granted. But without the domestic labour provided in and through the household, ‘there would be no labour force and no society’ (Townsend and Momsen 1987). Not only is the household at the nexus of social reproduction, which encompasses biological reproduction – if not generational, then that associated with daily sustenance – cultural reproduction, and consumption, but it is also the site of economic production, including both paid and unremunerated work. The balance between these activities – as much as who carries them out and for whom – is a social question. While household members manage, maintain, perpetuate, contest and sometimes change these arrangements and the social relations that hold them in place, they do so in a particular historical and geographical context.

Prior to the interventions of feminist theorists beginning in the late 1970s (see feminism), the household was assumed to include affectively related individuals with largely homogenous interests, and altruistic and co-operative intentions towards each other (e.g. Folbre, 1986), but as Townsend and Momsen (1987) long ago cautioned, the household can be an ‘arena of subordination’. It is a realm of differentiated and unequal social relations, structured by age, class, ethnicity, gender, life course, nationality, race and sexuality (e.g. Brydon and Chant, 1989). These internal divisions, which are associated with particular and shifting divisions of labour and allocations of resources, are constituted by – as they are constitutive of – broader social relations of production and reproduction. Household composition; location (whether matrilocal, patrilocal or neither); power dynamics, such as who heads the household and under what terms implicit or explicit; and the allocation of work and consumption practices among members are effects of this interrelationship. These differences are historically and geographically contingent. If capitalist industrialization has been associated with the separation of home and work, and households of individuals or nuclear families tend to predominate in the global north, while extended family households are more common in the global south, it is important to remember that these differences themselves vary according to class, race, ethnicity, sexuality and location, among other things.

**housing class** A social group defined by its housing tenure (Rex and Moore, 1967). It suggests that tenure status shapes the material conditions of life. Rex developed a categorization of housing classes – including owners, tenants in publicly or privately owned housing, and lodgers in another household’s dwelling, among others – which permitted analysis of the experiences of immigrant groups in the UK and emphasized the role of urban managers and gatekeepers in constraining housing market choice (see housing studies). Those interested in urban politics have also debated the concept, since it suggests that housing class interests might be the basis for collective political action (Purcell, 2001).

Rex and Moore (1967).

**housing studies** An interdisciplinary field with a wide array of research foci, dealing with aspects of housing from property market dynamics, through the provision and management of special needs accommodation, to questions of design and sustainability, among others. Geographical approaches to housing have frequently addressed the uneven geographies of housing production, consumption, meaning and policy. These uneven geographies reflect and produce differences in housing within cities, across countries, and between more- and less-developed countries.

One focus is the provision of housing via various mechanisms (Ball, Harloe and Martens, 1988). The production process leads to the spatial segregation of certain types of housing and therefore, certain people in specific neighbourhoods – a process that is frequently inflected with racism. The nature of provision, tenure type, the cost of housing, and its quality and maintenance all vary in ways that impact its character not only as a shelter but also as a symbolic element of the landscape (e.g. Bunnell, 2002), as an investment and as a resource that shapes residents’ life chances.

For those with high incomes who can buy into neighbourhoods where the housing stock is appreciating, home ownership presents opportunities for capital gain. These
opportunities are, in many countries (e.g. the USA), supported by state policies that provide subsidies and tax benefits for homeowners or that, more generally, mitigate the negative impacts of other land uses on higher-income residential neighbourhoods (cf. URBAN AND REGIONAL PLANNING; ZONING). Low-income owners, on the other hand, frequently face discrimination based on income, race and other factors (cf. REDLINING; URBAN MANAGERS AND GATEKEEPERS) and are often penalized financially as risky investments. Furthermore, they frequently face instability in their neighbourhoods as a result, for instance, of GENTRIFICATION and URBAN RENEWAL. These conditions enforce and deepen existing patterns of social polarization.

Similarly, while housing – no matter what the tenure type – is a resource that aids in access to jobs and various types of services from shops to recreational facilities, it is a socially and spatially uneven resource. For example, high-quality food at reasonable prices is often difficult to find near low-income housing, as are high-quality, safe recreational facilities for children. These factors, among others, both reflect and reinforce inequalities relating to nutrition and health and are, in turn, directly related to housing (Smith and Mallinson, 1997).

The social, economic and geographical characteristics of housing production and CONSUMPTION are closely related to PUBLIC POLICY. In different countries and at different times, policy-makers see housing as a tool for and/or an object of policy intervention. Housing construction has been used to kick-start economies (cf. SUBURBANIZATION) and to re-shape INNER CITIES (cf. URBAN RENEWAL). It has also been central to attempts by states, charities and other organizations to improve social conditions such as health. The state’s decreasing role in public housing provision raises new challenges in this regard, but has been paralleled by growth in alternative forms of housing tenure associated with community development (DeFilippis, 2004) and in attempts to reduce the impact of housing development on the environment. human agency The ability of people to act, usually regarded as emerging from consciously held intentions, and as resulting in observable effects in the human world. Questions about whether individuals have the freedom to act or whether their actions are constrained, or even determined, by structural forces have been at the heart of many debates in contemporary HUMAN GEOGRAPHY.

At the turn of the twentieth century, individuals’ actions were viewed by geographers as being the result of a higher logic or force, whether the imperatives of ENVIRONMENTAL DETERMINISM or the conditioning of Sauer’s (1925) ‘superorganic’ notion of CULTURE. There were exceptions such as Vidal de la Blache’s (1926) POSSIBILISM, which allowed a range of possible actions to emerge from any situation, but for most the role of the individual was secondary to process.

In the 1950s and 1960s, the introduction of SPATIAL SCIENCE allowed a DECISION-MAKING agent, but only in as far as it followed the logic of NEO-CLASSICAL ECONOMIC modelling. The adoption in geography of structural versions of MARXISM also regarded individual motivations and interpretations as necessarily secondary to the determinants of the structures of HISTORICAL MATERIALISM. HUMANISTIC GEOGRAPHY emerged in the 1970s with the stated goal of reanimating geography, to put people and their thoughts, emotions and beliefs at the heart of the discipline. It offered a challenge to structural Marxism, which humanistic geographers felt offered ‘a passive model of man [sic] that is conservative and results in an obfuscation of the process by which human beings can and do change the world’ (Duncan and Ley, 1982, p. 54). Focusing on issues such as dwelling, LIFEWORLD and rhythms, humanistic geographers believed that social life was constructed through human actions. For them, structure appeared due to reification, and seemed ‘autonomous only because it is anonymous’ (Duncan, 1980). While there were attempts by some humanistic geographers to recognize the limitations of human agency – such as Ley’s (1983) focus on inter-subjectivity – most tended towards epistemological IDEALISM. This led to the criticism that humanistic geography was naïve about the limitations put on individual ability to act.

STRUCTURATION THEORY and REALISM sought to explain how social structures were both outcome and medium of the agency that constitutes them. Giddens’ (1984) structuration theory avoids the extremes of arguing that society is comprised of individual acts or is determined by social forces by holding these two extremes in tension with one another. It is through repetition that the acts of individual agents reproduce social structures such as institutions, moral codes, norms and conventions.
HUMAN ECOLOGY

Post-structuralists (see POST-STRUCTURALISM), following Foucault (1980a [1976]), argued that the coherent, independent subjectivity required for conscious agency is an epiphenomenon of discourse: there is no prior ontological self but, rather, a sense of selfhood is an effect of discourse. The ‘self-contained, authentic subject conceived by humanism to be discoverable below a veneer of cultural and IDEOLOGICAL overlay is in reality a construct of that very humanist discourse’ (Alcoff, 1988, p. 415). Others have critiqued the intentionality of HUMANISM and structuration theory where agency is equated with action, thus assuming intentionality and capacity to act. As a result, some have investigated PSYCHOANALYTIC THEORY to expose the motivations behind actions, to reveal that SUBJECTS are not entirely self-aware and self-fashioning agents. Feminists have reacted more powerfully to POSTMODERN and post-structural pronouncements of the ‘death of the subject’, wondering whether this had occurred just when the male, white, subject might have had to share its status with those formerly excluded from agency (see Fox-Genovese, 1986; Mascia-Lees, Sharp and Cohen, 1989: see also GLOBAL WARMING).

The structure-agency debate continued through the discipline’s CULTURAL TURN, with some fearful that the favoured discursive approach represented a new determinism that denied individual agency – see the debate between Duncan and Duncan (1996) and Mitchell (1995). For others, the privileging of discourse was an over-interpretation of agency, which regarded people as overly theoretical beings in their own decision-making. As a result, some have turned to ETHNO-METHODOLOGY and NON-REPRESENTATIONAL THEORY approaches in an attempt to record human agency without imposing the intentionality of discourse (Thrift, 1997c).

Another dimension of the debate over agency concerns the extent to which humans are the only active or creative agents. Traditional cultural geographers challenged the anthropocentric accounts of early agriculture by suggesting that certain plants and ANIMALS may ‘elect’ to live near humans rather than human subjects knowledgeably selecting species for domestication. Others have offered theoretically more sophisticated accounts of the effects of non-human actors. Haraway (1992, p. 331) suggests broadening our understanding of the place of agency, arguing that non-humans ‘are not actants in the human sense, but they are part of the functional collective that makes up an actant’, and has developed this in terms of the ‘CYBORG’ subject. Whatmore’s (2002a) ‘more-than-human’ geography similarly highlights the agency of a variety of objects (see ACTOR-NETWORK THEORY), and has offered an image of a NETWORK of capable, but not necessarily conscious, agents.

human ecology This term is in some ways as suggestive as it is substantive, at least from the standpoint of contemporary sensibilities in the geographical tradition of studying human-environment relations. Specifically, the term carries an almost seductive appeal in promising transcendence of the pervasive NATURE-SOCIETY dualisms that are widely noted and of considerable contemporary preoccupation in explorations of the geographies of socio-natures, techno-natures and the like (see, e.g., Haraway, 1997; Swyngedouw, 1999). And indeed, to the extent that the term is actually invoked by contemporary geographers, it is typically in the context of research on the human origins and implications of environmental change, and on the complex interrelations between societies and the biophysical RESOURCES and SYSTEMS on which these societies rely. For example, in their discussion of factors shaping social vulnerability to global CLIMATE change, Bohle, Downing and Watts (1994) invoke ‘human ecology’ to refer to highly specific relations between society and nature, but with emphasis on the ways in which ‘… social organizations and [social] reproduction (encompassing, for example, population growth) have direct implications for sustainability and how the environment is experienced in terms of RISK and threats …’ (p. 40). Notably, they reject the mere application of ecological concepts and methods to the study of human populations. Similarly, Bassett (1988) refers to human ecology [specifically human ecologists] in much the same way; that is, a concern with the articulations between human populations and key biophysical resources (somewhat consistent with the term ‘POLITICAL ECOLOGY’).

References to ‘human ecology’ should, however, be accompanied by knowledge of its polyvalence, not least as a product of the term’s history of usage by geographers and non-geographers. This history can be traced at least to the early twentieth century, when
human ecology was used to describe the object of geographical enquiry as well as in reference to the adaptation of concepts from the science of ecology for sociological analysis. Thus, in his 1922 presidential address to the Association of American Geographers, Harlan H. Barrows defined geography simply as ‘the science of human ecology’, a science concerned with ‘...the relationships existing between natural environments and the distribution and activities of man [sic]’ (Barrows, 1923, p. 3). And yet at virtually the same time, the Chicago School of Sociology was placing its influential stamp on human ecology, defined by Robert E. Park (1936, p. 1) as ‘...an attempt to apply to the interrelations of human beings a type of analysis previously applied to the interrelations of plants and animals’. The Chicago School, of course, featured not only Park’s work on the influence of racial difference in shaping the experience of newcomers and immigrants to the city of Chicago, but also Ernest Burgess and his development of a zonal model (Park, Burgess and McKenzie, 1925).

What is perhaps critical to note here (particularly in light of the profound influence of that the Chicago School would have on the emergence of urban geography) is that ‘environment’ for the likes of Park and Burgess primarily meant the built physical as well as the more general social and cultural environment of the city, including spatial configurations. This is somewhat at odds with contemporary connotations of human ecology, which tend to emphasize relations between human and non-human nature (cf. cultural ecology; political ecology). And while the Chicago School’s influence on urban geography is recognized (Harvey, 1973), Park understood at the time that his version of human ecology overlapped with geography. Yet, he attempted to relegate geography to a particularistic, descriptive enterprise, leaving to sociologists the development of a more nomothetic human ecology complete with generalizations and formal theory (Entrikin, 1980).

All of this seemingly arcane intellectual history matters, because contemporary use of the term ‘human ecology’ can carry a fuzzy imprecision. Moreover, the term has ‘baggage’, associated as it is with mechanistic, positivist conceptions of social and cultural relationships to the environment (however conceived) based on organicist metaphors of social formations borrowed from ecology. These are critiques (warranted or otherwise) long directed at the Chicago School(s) (for an early example of this critique, see, e.g., Gettys, 1940). The term is still somewhat widely invoked (particularly in environmental sociology) as a synthetic, holistic approach to understanding the interrelationships of different social formations and their biophysical environments, including the specific and often highly complex and interactive relations governing the mobilization of key material and energy resources on the one hand, and cultural (material and symbolic), institutional and technological trajectories of social development on the other. Considerable contemporary impetus is given to this line of work by attempts to understand the origins and implications of modern anthropogenic environmental problems by looking at how past societies (or non-industrial, non-Western ones) have precipitated, managed, responded to and been affected by environmental changes (Diamond, 1999; Harper, 2004). Yet fears of mechanistic, if not deterministic, renderings of the role of physical geographies in shaping social outcomes are this line of scholarship, particularly when it comes to formulate causal inferences and historical generalizations (Mazlish, 1999).

It also bears noting that human ecology is recognized as something of a contemporary field of holistic scholarly enquiry (complete with eponymous journal and a handful of academic departments). In this context, it is defined by Lawrence (2003, p. 31) as no less than ‘...the study of the dynamic interrelationships between human populations and the physical, biotic, cultural, and social characteristics of their environment and the biosphere’ (emphasis added). All this points to the need for geographers and others to consider carefully the polyvalence of this term, and to invoke it reflexively, and with some degree of caution. SP

human genome The complete set of genes that make up the DNA of a human being. It is one of a number of species genomes that constitute a form of bio-information in which biological material is translated from corporeal formats, such as an organic bank, to informational formats, such as a database. Creating genomes relies on the DNA-sequencing technologies developed in the life sciences since the 1970s that make it possible to extract DNA from whole organisms and to elucidate and annotate its structure in the form of coded information. This is a laborious process, involving various methods for separating out nucleotides (the building blocks for the polymer molecules
DNA and RNA, which act as the repositories of genetic information in the cell), usually by rendering them visible as a pattern of bands in an acrylamide gel that can then be ‘read’ manually (with the naked eye) or scanned photographically, to translate the banding sequence into a digital code made up of four genetic digits – A, C, G, T – which can be stored in large computer databases such as the Human Genome Project Database.

The sequencing of the human genome was achieved almost simultaneously by a team at the University of Cambridge led by Peter Sanger, in competition with a team led by Craig Ventner in the USA in 2001. Not only did the methods of these two teams differ but so, crucially, did their research ethos. Whereas the Sanger team advocated that genomic databases should be a public resource, the Ventner team advocated the commercialization of such databases through the ascription of intellectual property rights. (See also genetic geographies.)

human geography A major field of geography that is centrally concerned with the ways in which place, space and environment are both the condition and in part the consequence of human activities. The history of geography (see Geography, History of) as a systematic and ordered body of knowledge was long dominated by the physical and natural sciences. This did not preclude studies focusing on the variation of human activities on the surface of the Earth (on the contrary: see AREAL DIFFERENTIATION), but the modern sense of geography as a disciplined mode of intellectual enquiry emerged through those scientific formations and their constitutive interest in ‘making sense of nature’ (Stoddart, 1986, p. ix). The templates of the physical and natural sciences shaped the human sciences and the social sciences as a whole, but geography’s concern with the relations between peoples and their physical environments ensured that they marked human geography more than most. Those formations were not purely ‘scientific’: they were also philosophical, theological and irredeemably political and social. All of them were caught up in (and constituted through) relations of power.

A separate and distinctive human geography emerged alongside Physical geography soon after the admission of geography to the modern academy towards the end of the nineteenth century, and it gained considerable momentum in the 1920s from the reaction against ENVIRONMENTAL DETERMINISM. This ‘new’ human geography took two main systematic forms on both sides of the Atlantic: a COMMERCIAL GEOGRAPHY that laid many of the foundations for modern ECONOMIC GEOGRAPHY (epitomized by the handbooks produced by G.G. Chisholm from 1889 through to 1928) and a POLITICAL GEOGRAPHY (dominated by F. Ratzel, H.J. Mackinder and later I. Bowman) that was primarily concerned with the STATE, TERRITORY and GEOPOLITICS. Like many other disciplines of the period, both under-laboured for CAPITALISM and EMPIRE: for the extension of European and American power abroad through NETWORKS of COMMODITY circulation and military (especially naval) might (see Smith, N., 2005a). In doing so, the two sub-disciplines also underwrote what eventually came to be recognized as CULTURAL GEOGRAPHY, which at that time was charged with inculcating a sense of national IDENTITY and NATIONALISM at home, while exhibiting the non-white world in a series of overseas tableaux.

These systematic geographies intersected in several ways, most visibly in studies of REGIONAL GEOGRAPHY, and the political, economic and cultural interests that animated them were articulated with a special force in a distinctive ‘tropical geography’ (cf. TROPICALITY). Regional geographies all treated the physical environment as a foundation for human activity, but none of the systematic geographies was divorced from the study of NATURE either. Much of commercial geography focused on RESOURCE inventories; securing access to those same resources was a strategic concern of political geography; and cultural geography emphasized the varying relations between peoples and environments in different parts of the world. Ratzel’s ANTHROPOGEOGRAPHY had made this a touchstone of human geography, and subsequently Paul Vidal de la Blache (in France) and Carl Ortwin Sauer (in the USA) made equally cogent cases for the incorporation of the physical environment. For Vidal, this was a matter of disciplinary identity, even survival. He was no narrow disciplinarian, and geography was always closely allied to history in his vision of la géographie humaine. But he was taken aback by Emile Durkheim’s new science of sociology, which was laying claim to much of human geography as ‘social MORPHOLOGY’, and Vidal insisted that this would leave society
‘suspended in the air’. In his contrary view, drawing on advances in the physical sciences, it was essential to conceive of ‘Nature’ as providing a portfolio of opportunities within which societies and cultures made variable selections (see POSSIBILISM: Andrews, 1984). Sauer worked on the marchlands between geography and history too, and the studies produced by the first BERKELEY SCHOOL are often described as ‘cultural–historical geography’. He was also keenly interested in anthropology, however, and this led him to formulate an approach in which a collective (and quasi-Durkheimian) CULTURE worked on the raw materials of the so-called ‘natural landscape’ to produce a climactic CULTURAL LANDSCAPE that not only evolved over time but also differed from place to place.

Human geography’s interest in NATURE has continued to provide important axes of debate. The rise of SPATIAL SCIENCE after the Second World War briefly threatened to erase the physicality of human life from human geography, with many of its MODELS relying on the physical sciences for stimuli (either through physical analogies about the friction of distance or through NEO-CLASSICAL ECONOMICS, which was rooted in statistical mechanics). Many practitioners of spatial science in human geography soon returned to a consideration of environmental issues, however, through a BEHAVIOURAL GEOGRAPHY that urged the importance of ENVIRONMENTAL PERCEPTION and through a systems approach that dissected, or at any rate diagrammed, the intersections of nominally ‘human’ and ‘physical’ SYSTEMS. At that time, URBAN GEOGRAPHY was markedly less interested in these questions, and it took much longer for urban geographers to recognize that modern cities were not triumphant memorials to a human victory over ‘Nature’ and that the physico-ecological vertebræ of cities were crucial objects of enquiry. But it is now widely acknowledged that studies of POLLUTION, waste and WATER in cities address more than questions of public HEALTH and policy located at the crossroads of MEDICAL GEOGRAPHY and URBAN PLANNING: they also intersect with concerns about ENVIRONMENTAL JUSTICE, GOVERNMENTALITY and SOCIAL EXCLUSION that have become central to human geography more generally (see, e.g., Gandy, 2006a,c). This new agenda was advanced in part through a critique of spatial science that emphasized the material bases of CAPITALISM as a MODE OF PRODUCTION – the PRODUCTION OF SPACE was thus intimately related to the PRODUCTION OF NATURE, most viscerally in studies of POLITICAL ECOLOGY (Watts, 1983a; Peet and Watts, 2003 [1996]; Robbins, 2004) – and in part through an engagement with other forms of SOCIAL THEORY that brought the biopolitical foundations of modern life into view (see BIOPOLITICS). The convergences between these streams of work have suggested a series of intrinsically ‘hybrid geographies’ (Whatmore, 2002a).

These developments reactivated and reformulated long-standing questions about the relations between human geography and PHYSICAL GEOGRAPHY, but it is only recently that the relations between the sub-disciplines of human geography have provoked equal discussion. The relative importance of the sub-disciplines has changed over time. Many of the core models of spatial science were the main-springs for an ECONOMIC GEOGRAPHY dominated by LOCATION THEORY and driven by the search for systematic structures within a modern SPACE-ECONOMY. The subsequent critique of spatial science had many sources (Gregory, 1978a), but much of its vitality derived from a POLITICAL ECONOMY based on a close reading of Marx’s analysis of CAPITALISM. This not only reshaped economic geography, where it set the space-economy in motion and allowed for more incisive analyses of (for example) the crisis-ridden dynamics of capital ACCUMULATION, spatial DIVISIONS OF LABOUR, industrial RESTRUCTURING, COMMODITY CHAINS and the circulation of CAPITAL in multiple forms. It also opened the doors to a revitalized POLITICAL GEOGRAPHY that more closely and critically engaged with the powers and practices of the STATE, and a SOCIAL GEOGRAPHY that became centrally concerned with spatial formations of CLASS and ETHNICITY. These two sub-disciplines drew on contributions to SOCIAL THEORY that spiralled far from Marx’s original writings – though a diffuse Western MARXISM remained a significant source of inspiration to both of them – and these interactions issued in the rise of CRITICAL GEOPOLITICS and the emergence of vigorous FEMINIST GEOGRAPHIES that widened their horizons still further. These interdisciplinary exchanges also projected a central question for the HUMANITIES and the social sciences into the centre of human geography. Just as there were (for example) ‘two anthropologies’ and ‘two sociologies’, one emphasizing HUMAN AGENCY and the other emphasizing systems and structures, so there were two human geographies: one an avowedly HUMANISTIC GEOGRAPHY (in which IDEALISM vied with MATERIALISM) and the other much more invested in structural logics and
constraints (but not reducible to a STRUCTURALISM). STRUCTURATION THEORY proposed to replace this persistent duality with a duality, but this promised to do much more than integrate ‘agency’ and ‘structure’ in explications of the conduct of social life: it also made PLACE and SPACE the pivots around which agency and structure turned. This further troubled the boundaries between contemporary and HISTORICAL GEOGRAPHY, already assailed by HISTORICAL MATERIALISM, because TIME as well as space was seen as focal to the production and reproduction of social life. In a sense, this vindicated older claims that ‘all geography is historical geography’ and socialized the formalism of classical DIFFUSION models, though in terms that their original protagonists would scarcely have recognized. These developments were reinforced by the ‘CULTURAL TURN’, which inaugurated a ‘new’ CULTURAL GEOGRAPHY whose development was marked by a series of theoretical ‘posts’ – POSTMODERNISM, POST-STRUCTURALISM and POST-COLONIALISM – though here too Marxisms in various forms continued to provide baselines for many geographers (Soja, 1989; Gregory, 1994).

This simple sequence is necessarily a caricature – human geography is not a single project and its history cannot be reduced to a linear narrative – but it does capture some of the major shifts in intellectual fashion in human geography in much of the English-speaking world since the Second World War. To describe them as fashion is not misleading; the links between CULTURAL CAPITAL, the commodification of knowledge and academic prestige ought not to be discounted. Yet they were also more than fads. While it would be misleading to plot these changes in an ascending arc of ‘progress’ in human geography, they have derived from intellectual debates inside and outside the discipline, and they were responses to issues of substance that required public address. This is clear from the theoretical sensibility that distinguished postwar human geography from its predecessors. Although few would welcome a return of the grand theory that preoccupied many areas of human geography as recently as the late twentieth century, critique as a rigorous interrogation of the ways in which concepts are freighted with relations of POWER is now firmly established as a central moment in geographical enquiry (cf. GENEALOGY). It is also clear from the success of both CRITICAL HUMAN GEOGRAPHY and RADICAL GEOGRAPHY in establishing the crucial importance of POLITICS alongside the narrower and usually more instrumental focus on policy in APPLIED GEOGRAPHY, although Martin (2001b) complained that what he saw as ‘faddishness’ (in philosophy and theory) has limited the practical purchase of much of this contemporary work.

These developments have contributed to a considered blurring of the boundaries between the sub-disciplines of human geography; economic geography and political geography were brought into conversation through POLITICAL ECONOMY, for example, and both have been markedly affected by a CULTURAL TURN (see also CULTURAL ECONOMY) that requires recognition of the commodification of cultural forms and practices and their enrolment in economic and political figurations (cf. Harvey, 1989b). This ‘blurring’ has several sources. ‘Theory’ has itself become interdisciplinary, even postdisciplinary, and the same authors and texts, motifs and themes recur across the spectrum of the humanities and social sciences, while any CRITICAL THEORY worthy of the name cannot draw back when it encounters disciplinary boundaries. More than this, however, compositional approaches that separate ‘economy’, ‘polity’, ‘society’ and ‘culture’ – all of them at once as real and as constructed as the disciplines that have come to be identified with them: they are all fabricated rather than found objects – are confounded by geography’s constitutive interest in the contextual: in the coexistence of objects, institutions and practices in time and space (cf. Hägerstrand, 1984, pp. 374–5: see also CONTEXTUALITY).

It is thus not surprising that the interactions between human geography and the other humanities and social sciences should have been a two-way street. It is perfectly true that many of the early encounters were largely derivative. Methods and theories were borrowed from other fields and put to work on the research frontier in order to stake a series of supposedly distinctive geographical claims (and, not coincidentally, to identify the adventurousness of the intellectual avant-garde). Gradually, however, a return flow was established and cross-disciplinary exchange increased:

1. Human geographers have made substantial METHODOLOGICAL contributions. Among the most significant have been those to mathematical and statistical analysis, particularly through advances in the study of SPATIAL AUTOCORRELATION that address the problem of applying techniques associated with the GENERAL LINEAR MODEL to spatially referenced data, and the development of GEOGRAPHICAL INFORMATION SYSTEMS that have
made it possible to display and interrogate vast, spatially distributed data arrays; and to modes of visual analysis through critical readings of the spatialities of ART, CARTOGRAPHY, FILM and photography (see VISUAL METHODS). Yet these methods have been unevenly developed and deployed: QUANTITATIVE METHODS have always been most important in economic geography, where they are presently undergoing a considerable resurgence; studies in ELECTORAL GEOGRAPHY have been the principal locus of quantitative work in political geography, which has otherwise preferred qualitative methods, especially in CRITICAL GEOPOLITICS; and cultural geography has been almost entirely produced through QUALITATIVE METHODS.

(2) Human geographers have also made significant theoretical contributions. An explicit interest in theorization was a lasting achievement of spatial science: the so-called QUANTITATIVE REVOLUTION was often hailed as a local ‘scientific revolution’, but it was fundamentally a theoretical revolution, and it was the commitment to theorization that did much to constitute human geography as a research discipline (and en route to facilitate conversations with other disciplines). In the 1960s there were several calls for the development of a distinctively geographical body of THEORY: a theoretical corpus that would be the exclusive preserve of geography and thus serve to guarantee its intellectual and institutional legitimacy. At the end of that decade, Harvey concluded his prospectus for Explanation in geography (1969) with an injunction: ‘By our theories you shall know us’. This was always an unlikely prospect at best (and a dangerous one at worst), and most human geographers – including Harvey himself (see Castree and Gregory, 2006) – became much more interested in establishing the interdisciplinary significance of place and space for social analysis. This has itself been an interdisciplinary project, not least because, as Harvey has constantly emphasized, the incorporation of such spatial concepts (the contextual) into conventional social theory (the compositional) is radically unsettling. What is sometimes called ‘the spatial turn’ has thus been described by more than human geographers: so much so, in fact, that accounts of LANDSCAPE, PLACE, REGION and SPACE have become commonplace in many areas of the humanities and social sciences (Crang and Thrift, 2000; Hubbard, Kitchin and Valentine, 2004; Warf and Arias, 2008).

The developments summarized in the previous two paragraphs resulted in what Kwan (2004) identifies as a divide – even a ‘rift’ – between ‘spatial–analytical geographies’ invested in the development and use of quantitative techniques and geospatial technologies on one side and ‘socio-cultural geographies’ involved in the development and use of critical social theory and more qualitative methods on the other. Kwan insists that this is unproductive: there is no direct and immediate relation between EPistemology and method, she insists, so that ‘the choice between critical social theory and spatial analysis is false.’ She urges the development of ‘hybrid geographies’ that ‘challenge the boundary and forge creative connections between socio-cultural and spatial–analytical geographies’ (p. 758). Kwan’s hybrid geographies are not (quite) Whatmore’s (2002a) hybrid geographies, but they both speak of transcending the divisions between the cultural, social or ‘human’ sciences and the biological, physical or ‘natural’ sciences, and they both emphasize the role of feminist theories and FEMINIST GEOPHraphies in ‘talking across the divide’ (cf. Kwan, 2007).

In disciplinary terms, however, what matters most is the substantive work carried out under the sign of human geography. Although they are unlikely soul mates, Martin (2001b) and Harvey (2006c) have both criticized what they characterize as the deflection of human geography from rigorous, substantive inquiry through a fixation on, even an obsession with, abstract philosophical and theoretical issues. Although they were writing from opposite sides of the Atlantic, their complaints were largely addressed to a British audience and arise, in part, from recent differences in intellectual history and institutional context. It has become increasingly difficult to identify a common ‘Anglo-American’ human geography (cf. Johnston and Sidaway, 2004a,b), a development that has coincided with an emerging critique of Anglo-American Hegemony within the international discipline(s). If the coincidence seems ironic, this last critique is about more than LANGUAGE: it is about language used to privilege particular conceptual formations. And the criticisms made by Martin and Harvey also arise from opposition to equally particular philosophies and modes of theory. PHILOSOPHY was once given extraordinary
legislative authority in human geography, particularly the philosophy of science, and standard textbooks have commonly distinguished different philosophical traditions and mapped them more or less directly onto human geography (Johnston, 1986b [1983]; Cloke, Philo and Sadler, 1991; Peet, 1998) (see phenomenology; positivism; realism; structuralism). But as human geographers were drawn away from foundational philosophies like these and, coincidentally, into considerations of political and moral philosophy, so they became less impressed by exclusively scientific credentials and the power of Philosophy-with-a-capital-P to provide them (see hermeneutics; pragmatism; post-structuralism). Many of the philosophical writings that have attracted human geographers in recent years have engaged most directly with (and transformed) the core concerns of the humanities and the human sciences – see, for example, deconstruction, discourse and performativity – and in doing so they have opened up wholly new areas of geographical reflection: affect, desire, memory and the like. This has produced a complex terrain in which different philosophical concerns have been brought into relation and juxtaposition with one another, and where philosophy has come to be treated more as a resource and less as a tribunal. Similarly, it was once possible to map human geography as a series of positions on an intellectual landscape that was, in effect, an absolute space: theoretical coordinates established the singularity of different systems of concepts. But here too there has been a sea-change, and most human geographers now accept that no one theoretical system can ask all the important questions, still less provide all the cogent answers. They thus find themselves working in (and producing) the tense space between contending and colliding systems of concepts. The result of these philosophical and theoretical innovations has been to shake the very foundations of enquiry in human geography, as they have in the other humanities and social sciences, and the oppositions that once skewed the field (such as ‘agency’ and ‘structure’, but the list is now much longer) have been called into radical question (Cloke and Johnston, 2005). A second response, then, might be that critics such as Martin and Harvey lament these tectonic shifts and yearn for solid ground (though they undoubtedly stand in different places on it).

Whatever one makes of this, however, their point remains a sharp one. It is not difficult to see why the demands of navigating this new terrain should have prompted some human geographers to become so preoccupied with philosophical and theoretical issues that these become not so much moments in as substitutes for substantive inquiry: a refuge from the capriciousness and, indeed, riskiness of the empirical. On this reading, it is symptomatic that of the 26 ‘key texts in human geography’ identified by Hubbard, Kitchin and Valentine (2008), barely a handful focus on the results of empirical analysis. But there are many other key texts, and many writers have reactivated and reformulated sites that have long been focal to human geography – borders, cities, industries, regions and territory, for example – and opened up new ones, such as the body, the home, the shopping mall, the prison and the zoo. They have reworked traditional themes in both the past and the present, including colonialism, development, imperialism, industrialization, modernization, urbanization and war, and explored new ones such as film, law, money, music, performance, sexuality, terrorism and tourism. And there has been a continuing stream of principled work on different places and their interconnections that collectively gives the lie to the monstrous assertion that ‘the world is flat’ (cf. Smith, 2005a: see globalization). It would take a brave or foolhardy person to issue a programmatic statement in the face of such diversity, but this has not prevented attempts to chart the future of human geography. The spirited reactions to Harvey’s (1984) ‘historical materialist manifesto’, or Amin and Thrift’s (2005a: cf. Thrift, 2002) revisionist prospectus twenty-odd years later, testify not only to the diversity of human geography, but also to a continued vitality that depends on an irreplaceable intimacy between theory and practice.

human rights  A RIGHT is an entitlement that is usually encoded in a legal context (see law). One can distinguish between human rights and citizenship rights. Citizenship rights are guaranteed by governments for nationals of a particular territory, whereas human rights are thought to be geographically and politically universal. Hannah Arendt (1973) warned that human rights are the least desirable rights because they imply the absence of protection by a nation-state; the rights of citizens are superior to human rights because they are...
both applicable and enforceable. Matters are not that simple, however, because rights may be, and in fact often are, legally suspended during a ‘state of emergency’ (see exception, space of).

The liberal model of rights is derived from seventeenth-century political thought that focuses on the rights accorded to individuals as well as the obligations that individuals owe society and the state (Kofman, 2003). Critics of liberalism question the scale at which rights are borne – in other words, that of the individual – and highlight group or communal rights (Isin and Wood, 1999), or deconstruct political community as pre-given (Mouffe, 1992). Despite the limits of liberalism and rights-based political change, Blomley (1994, p. 410) argues that ‘[r]ights have not gone away. As such, the dismissal of rights-based struggles as incoherent or counter-progressive seems condescending.’ Blomley and Pratt (2001) contend that rights are open to a variety of readings, their meaning indeterminate. Rights can be mobilized effectively at different scales to constructive ends.

Pratt (2004, p. 85) explores the limits and possibilities of human rights discourse, noting that any form of the universal is ‘necessarily exclusionary but paradoxically holds within it the means to be challenged by those who are excluded by it’. This paradox is evident in the struggles of the Filipino caregivers who live in their employers’ homes and trade their freedom and mobility for paid work. Pratt maps the ways in which rights are mobilized in different spaces: at the scale of the body, between the [private] home and [public] Canadian society, in the context of the Canadian state and on the global commons. Similarly, Bosco (2006, 2007) charts the ways in which human rights have been fought for by the Madres de Plaza de Mayo in Argentina through the mobilization of a series of territorially dispersed social networks.

Practically speaking, human rights have been encoded in United Nations documents and institutions, and in international law, since the Second World War. In 1948, the Universal Declaration of Human Rights was adopted, though it was not legally binding (it was a declaration, not a treaty). In 1966, two legally binding human rights instruments were created to protect civil and political rights, on the one hand, and economic, social and cultural rights on the other. These covenants depend upon the ratification of a sufficient number of states, which they received in 1976.

The provisions of the International Covenant on Civil and Political Rights have been privileged over those of the Covenant on Economic, Social and Cultural Rights. The first ensures respect for citizens regardless of language, religion, sex, political opinion and so on, as well as the right to liberty of movement and freedom. The latter includes provisions that are more applicable to developing countries than to highly industrialized ones, such as the right to food, shelter, work, and basic medical and educational services. While the first covenant applies to individuals, the second refers to particular groups of people.

Tensions exist between the sovereignty of states to govern and the human rights of their citizens. The slippage in scale between the state with its right to govern and individuals with human rights can be traced to the potentially contradictory terms enshrined in the 1945 UN Charter and the 1948 UN Declaration of Human Rights. While the ‘General Assembly shall . . . [assist] in the realization of human rights and fundamental freedoms for all without distinction as to race, sex, language, or religion’ (Article 13 (1b)), its constituent members are states whose sovereignty and security prevail. The UN Charter has mechanisms to ensure the protection and enforcement of peace and international security, but it outlines few obligations for the protection of human rights.

Since the early 1990s, the UN Security Council has extended the meaning of what constitutes a threat to international peace and security in the Charter, and increased the conditionality of sovereignty. Developing countries have expressed concern about this interpretation as potentially interfering in internal affairs. Sovereignty is seen as a last line of defence against the will of the (largely Western) ‘international community’. While the UN remains an organization comprised of member states within a framework of liberal rights and freedoms, it has challenged the abuse of sovereignty in places such as northern Iraq, Bosnia-Herzegovina, Somalia and East Timor. Sovereignty is qualified, and the abrogation of people’s human rights within a given state is no longer a domestic matter, at least with a UN context.

There are many human rights instruments that have been ratified, including the Convention on the Elimination of Discrimination against Women (CEDAW) and the Convention on the Rights of the Child (CRC). The USA has signed neither of these legal instruments, illustrating that unilateralism by the world’s superpower
humanism A philosophical tradition that places human faculties (reason, consciousness and the like) at the centre of human action in order to account for and inform conduct. Humanism has a long history in European PHILOSOPHY, where it is usually traced back to the Renaissance, but it played a pivotal role in much later reformulations of modern HUMAN GEOGRAPHY. The architects of an explicitly HUMANISTIC GEOGRAPHY used a broadly based humanism as a crucial foundation for their critique of SPATIAL SCIENCE. To Tuan (1976b, p. 266), humanism in its various forms provided ‘an expansive view of what the human person is and can do’. ‘More comprehensive than science’, he continued, humanism accords a central place to those uniquely human capacities that lie at the core of the humanities: consciousness, critical reflection and creativity that in turn inculcate a sense of historicity. While he did not see humanism as an alternative to ‘scientific geography’, Entrikin (1976, pp. 616, 632) argued that such an approach ‘helps to counter the objective and abstractive tendencies of some scientific geographers’ and reviewed the twin philosophies of EXISTENTIALISM and PHENOMENOLOGY to reaffirm ‘the importance of the study of meaning and value in human geography’. Others insisted on the political and ethical significance of humanism. A stream of work on HUMAN AGENCY and human geography challenged the narrowly conceived and often deterministic assumptions about human action that had been incorporated into both spatial science and BEHAVIOURAL GEOGRAPHY (Ley, 1981) and reworked one of Marx’s iconic statements thus: ‘People make geography, but not just as they please and not under conditions of their own choosing’ (Gregory, 1981). Others treated humanism as a well-spring for ethical reflection: ‘The recovery of the human subject’, Buttimer (1990, p. 28) concluded, allowed for what would now be called a COSMOPOLITANISM and a heightened sensitivity to what she identified as ‘the “barbarism” of our times’ (see also ETHICS).

Even as these claims were being registered, however, Cosgrove provided a series of compelling reconstructions of the historical trajectory of humanism that suggested a less celebratory interpretation. Focusing on the concept of LANDSCAPE, Cosgrove (1984) showed that Renaissance humanism was about certainty rather than individual subjectivity, and that it was deeply implicated not only in the geometric obsessions that the critics of spatial science sought so strenuously to repudiate, but also in a visual IDEOLOGY that underwrote a constellation of distinctively bourgeois POWER and privilege. Others took different routes to arrive at parallel conclusions. Approaches through FEMINIST GEOGRAPHY and POST-COLONIALISM revealed that the supposedly universal ‘human subject’ at the centre of conventional humanism was not only a SUBJECT whose class position was artfully unmarked, as Cosgrove had shown, but also a subject whose heterosexuality, masculinity and WHITENESS were concealed too. Seen thus, humanism was exposed as a normative political–ideological project. Many of these subsequent critiques were informed by POST-STRUCTURALISM, which licensed what came to be categorized as an ANTI-HUMANISM: an approach that, far from being uninterested in or dismissive of human subjects and human actions, seeks to analyse the multiple ways in which different human subjects are constituted. This project has been radicalized by a POSTHUMANISM that, critical of the anthropocentrism shared by humanism and anti-humanism, admits non-human actors to the production of nominally ‘human’ but in fact constitutively ‘hybrid’ geographies.

Similar critiques have been mobilized to question and contest the rise of what Douzinas (2003) calls a ‘military humanism’ that promotes military intervention and WAR in the name of supposedly universal HUMAN RIGHTS, or ‘Humanity’ more generally. These projects often promote, on their dark side, the co-production of spaces of exception (see EXCEPTION, SPACES OF), whose denizens are constructed as sub-human and hence unworthy of protection. Here, humanism functions as a sort of anthropological machine, conferring and withdrawing the status of ‘human’ from its objects (cf. BARE LIFE). DG

humanistic geography An approach that seeks to put humans at the centre of GEOGRAPHY. Accounts of disciplinary history have created for humanistic geography a sense of...
singularity of vision that overlooks the multiple, and sometimes conflicting, approaches that humanistic geographers have adopted. They have drawn upon a wide range of humanist philosophies, which has led to a generic humanistic geography in addition to versions based around ESSEntIALISM, IDEALISM, PHENOMENOLOGY and PRAGMATISM (see also HUMANISM). Despite this, there are key similarities in terms of the reasoning behind the emergence in the 1970s of humanistic geography; it was a response to what were seen as the dehumanizing effects of both POSITIVISM and structural MARXISM, in addition to promoting a positive model of a humanistic geography. Buttimer has argued that:

From whatever ideological stance it has emerged, the case for humanism has usually been made with the conviction that there must be more to human geography than the danse macabre of materialistically motivated robots which, in the opinion of many, was staged by the post-World War II ‘scientific’ reformation. (Buttimer, 1993, p. 47)

For many humanistic geographers, the world is primarily the sum of human experiences through their encounters with ‘external reality’, which cannot be accessed other than through the human mind (Cloke, Philo and Sadler, 1991). However, others were less reductionist, and recognized that the ‘external’ world was mediated through subjective layers of meaning in complex ways. Talking of ‘body–subject’ to transcend the separation of material life from thought, Seamon (1979) sought to capture the meaning of PLACE that was orchestrated through the ‘pre-reflective intentionality’ of ‘body ballets’ – the movement, often unthinking and unroutinized, of people through their environments, weaving the rich texture of place (a view echoed by recent returns to ETHNOMETHODOLOGICAL techniques and feminist theorizations of the BODY).

This is not simply an ONTOLOGICAL move in terms of focusing on individuals and their various activities, but also a philosophical one which puts human experience and understanding of the world at the centre of geography. It further insists that all human experience is articulated through geographical concepts such as SPACE, TIME and LANDSCAPE. Drawing on Husserl’s PHENOMENOLOGY, Buttimer (1976) talked of the concept of the LIFEWORLD to provide a sense of this intimacy between place and people (see also Seamon, 1979). Thus, appropriate QUALITATIVE METHODS are required, as ‘[n]o decimal notation of time, no geometric commandment, no camera or tape recorder could easily articulate the experience of this lifeworld’ (Mels, 2004, p. 3). Phenomenological strands of humanistic geography were concerned with essences – for example, of space or experience (Tuan, 1976b) – or with the nature of existence, elucidating previously taken-for-granted ways of being in the world.

In their attempts to articulate the human experience of place and landscape, some humanistic geographers turned to the humanities, particularly ART and literature, as forms of expression that were seen to provide insights that were unavailable to the more scientific gaze of the geographer (Meinig, 1983). However, the enthusiasm of some (e.g. Pocock, 1981) for the transcendental ability of the artist or author to capture the essence of human experience has been criticized for its ignorance of the common origins of European Renaissance artistic representation with geometric knowledges of possession and control (Cosgrove, 1984), and the nature of genres in literature (Sharp, 2000b).

In addition to drawing the human as the subject of geography, humanists also turned to examine the humanity of the geographer. The emphasis on interpretation and intersubjectivity that humanistic geography pronounced meant that the researcher could not be seen as ‘an individual whose humanity stands outside the research process: as an individual who is nothing but a vessel for taking in information, processing it and then arriving at conclusions’ (Cloke, Philo and Sadler, 1991, p. 71). Instead, the researcher had to acknowledge her or his role in the process of interpretation and the production of knowledge, and thus Buttimer (1974) stressed the importance of VALUES in geography. This necessitated the adoption of ETHNOGRAPHIC and participatory research METHODOLOGIES (e.g. Ley, 1983; Western, 1992) and experiments with writing styles to move away from sterile scientific LANGUAGE (e.g. Olsson, 1991).

Because humanistic geography emphasized experience and human SUBJECTIVITY, it tended towards idealism and voluntarism, and as a result has been criticized, particularly by MARXIST, REALIST and STRUCTURATIONIST theorists for overplaying the freedom that individuals have to act and for tending to focus on the micro-scale at the expense of important structural connections (although, in both cases, note E.P. Thompson’s socialist humanism). Despite superficial similarities, the CULTURAL TURN in human geography has offered a critical
challenge to humanism, and most ‘new cultural geography’ is characterized by post-humanisms of various sorts. Theorists of post-structuralism would further suggest that the perception of human agency so promoted in humanistic geography is a product of dominant discourse. Feminist geographers have shown how these dominant discourses create an image of normal subjecthood that is white, male, bourgeois, heterosexual and able-bodied, an image that can only be maintained as coherent through the exclusion of all that is ‘Other’ (see feminist geographies). Thus, a whole range of others are denied full subjectivity and agency (Alcoff, 1988). The exposure of the fiction of coherent subjectivity has also led some to turn to psychoanalytic theory to seek to understand unconscious motivations for actions, something overlooked by many humanistic geographers who regarded human agency as the result of conscious decisions (but again, there were exceptions, such as Seamon’s ‘body-ballets’). Recent developments of post-humanism, or what Whatmore (2004) has called ‘more-than-human’ geographies, have sought to populate the world with agents other than humans (see actor-network theory).

Although these critiques have meant that the influence of humanistic geography per se has waned since the 1980s, many of its arguments are still key to current debates in human geography. Recent critique of the cultural turn insists that geographers’ enthusiasm for discourse and representation have drawn them away from ‘the more “thingy”, bump-into-able, stubbornly there-in-the-world kinds of “matter” (the material)’ (Philo, 2000a, p. 33). New cultural geographers’ presentations of landscapes as already structured through discourse draw attention from the variety of corporeal practices as instances of how ‘senses of landscape and self are mutually configured’ (Wylie, 2005, p. 239). Wylie (2005) talks in terms of a ‘post-phenomenology’ in which human agency is reconnected with networks of non-human agents, through which place and experience emerge. jsh

humanities  Emerging in Europe during the Renaissance from medieval scholastic study of the seven liberal arts (i.e. the quadrivium of arithmetic, geometry, music and astronomy, and the trivium of rhetoric, logic and grammar), the humanities today denotes both an approach to knowledge and a specific set of disciplines (see also humanism).

As an approach to knowledge, the humanities are (still) characterized by broadly hermeneutic or interpretive methods and work through cycles of criticism rather than the establishment of theory and scientific law (see law, scientific), although concepts, the rule of evidence and logical argument are vital to their practice. Expressions of this include privileging the monograph or essay rather than the research paper as the preferred style of scholarly communication, individual authorship, and the use of the footnote or endnote rather than the ‘Harvard’ referencing system, suggesting ‘conversation’ rather than progressive and cumulative advance of knowledge (Smith, J., 1992a). The humanities thus foreground the active role of the author in the construction of knowledge and understanding (Cosgrove and Domosh, 1993).

The humanities disciplines concern the study of distinctively human actions and works; for example history, philology (language, literature, linguistics), philosophy, theology and studies of Antiquity. The principal goals of the humanities are both active and contemplative: they were long regarded as fundamental to the educational preparation of rulers, but their success was gauged in part by the degree of self-knowledge and self-reflection they produced in the student (Grafton and Jardine, 1986). Geography, sometimes characterized as the ‘eye’ of history, as history in turn was proclaimed ‘queen’ of the humanities, has a long record as a humanities discipline, initially because it based its knowledge of the world upon the authority of ancient texts and subsequently, as exploration, autopsy and empiricism displaced such authority, because it entailed the comparative study of places and peoples.

The evolution of modern geography as a university discipline has been strongly affected by both natural science and social science epistemologies and methods, although historical geography’s natural allegiance with history has continuously if contentiously sustained geography’s connection with a key humanities discipline. The rhetoric of ‘science’ within geography has long tended to subordinate a broader humanities tradition, although recent studies of science as a social, irredemably human practice have not only drawn in some measure from the humanities but also interrupted the authority of science understood as objectivism. The values and value of humanities scholarship have also been marginalized by geography’s postwar focus on
research, policy relevance and critique as opposed to pedagogy. A self-styled ‘humanistic’ geography in the 1970s and 1980s (Ley and Samuels, 1978) owed less to conventional humanities study than to then fashionable psychological theories and twentieth-century phenomenology, but it opened human geography to questions of perception and interpretation that had long been associated with the humanities (see *humanistic geography*). Probably the most productive and widely read contemporary practitioner of geography as a humanity is Yi-Fu Tuan, whose autobiography is explicit about his practice of geography as a vehicle for self-understanding through reflection on the true, the good and the beautiful in a world of places and landscapes (Tuan, 1999).

Many human geographers are profoundly sceptical of the universalistic claims of ‘humanity’ and the humanities’ focus on individual agency (both in subject matter and authorship), and indeed many contemporary scholars in the humanities have also sharply questioned such traditional orthodoxies (see *post-structuralism*). But recent critical and cultural study within human geography signals the discipline’s engagement in the convergence of social sciences and humanities that has emerged with the rejection of positivism and the embrace of interpretive methods on the part of the former, and acceptance of the value of social theory on the part of the latter (see also Gregory, 1994). The ‘cultural turn’ has thus seen human geographers working with both materials and methods conventionally associated with the humanities – for example, the interpretation of texts and images – although the ‘new’ cultural geography represents an uneasy alliance between those pursuing a traditionally social science agenda and those who cleave to the more conventionally individualistic, reflective and pedagogical concerns of the humanities. Still, that the Association of American Geographers could convene a major interdisciplinary conference on ‘Geography and the Humanities’ in June 2007 says much about the salience of contemporary conversations between the two, appropriately enough, and hence about the continuing importance of the humanities in geography and geography to the humanities.

Tuan (1996).

**hunger** The right to food – and relatedly the right to not starve – represents one of the foundations of international and national human and political rights. The Universal Declaration of Human Rights (1948), the International Covenant of Economic, Social and Cultural Rights (1964) and the UN Millennium Declaration (2000) all refer to freedom from hunger as a basic and inalienable human right. The reality is, of course, very different. According to the Food and Agriculture Organization (FAO), there are 854 million people undernourished worldwide (FAO, 2006): 820 million in the developing world, 25 million in the transition (former socialist) countries and 9 million in the industrialized states. Virtually no progress has been made towards the Rome World Food Summit (1996) target of halving the number of undernourished people by 2015. There has been little change in developing-world hunger since 1990–2. It is true that the proportion of undernourished people has fallen by three percentage points, but the FAO projects that it is unlikely that the UN Millennium Goal for hunger will be met. The Near East, South Asia and especially sub-Saharan Africa have seen sharp increases in the number of hungry people; currently, 33 per cent of sub-Saharan Africa is undernourished.

**Poverty and hunger** and hunger are very much part of the landscape of the twenty-first century. In the period since 1980, economic growth in 15 countries has brought rapidly rising incomes to 1.5 billion people, yet one person in three still lives in poverty and basic social services are unavailable to more than 1 billion people. Nowhere is this privation more vivid and pronounced than along gender lines. Of the 1.3 billion people in poverty, 70 per cent are women. Between 1965 and 1988, the number of rural women living below the poverty line increased by 47 per cent; the corresponding figure for men was less than 30 per cent (UNDP, 1996). A key measure of poverty is the extent to which individuals are able to secure sufficient food to conduct a healthy and active life. By the conventional measure of hunger, namely the FAO’s definition of household food security (HFS) ‘[physical and economic access to adequate food for all household members, without undue risk of losing such access’ (FAO, 1996, p. 50)], millions of people are not household food secure. The FAO provides a number of measures pertaining to food, hunger and undernutrition. Currently, over 800 million consumed so little food relative to requirements that they suffered caloric undernourishment (which often leads to anthropometric deficiency and the risk of damaged human development). Malnutrition (or undernutrition) refers to physical conditions that result from the interaction of inadequate diet, poor food consumption,
nourishment or food intake but are food insecure – however, their conditions may change very rapidly and throw them into abject hunger. These differing forms of security and vulnerability are intimately wrapped up with the sorts of entitlements and protections afforded to different classes, genders, ages and social groups.

Currently, global food consumption provided 2720 dietary calories per person, which would have been sufficient if distributed in proportion to requirements. In global terms, then, food consumption is so unequal that caloric undernourishment is serious. It is true that the proportion of malnourished people has fallen greatly (more in the past 50 years than in the previous 3000) but hunger and undernourishment remains endemic in some regions (notably sub-Saharan Africa and South Asia). Paradoxically, there is much evidence to suggest growing hunger in some of the North Atlantic economies and within a number of post-socialist societies. According to the International Food Policy Research Institute (see Von Braun, Serova, tho Seeth and Mely 1996), agricultural production fell by 30 per cent in Russia between 1989 and 1994 and hunger was widespread during the 1990s. In California (a place where the more affluent are seemingly obsessed by eating less and losing weight), the reform of ‘welfare as we know it’, has produced 8.4 million who were ‘food insecure’ by 2000.

A conventional way to think about hunger is in terms of output or gross availability. Food security decreases accordingly as food availability declines. Famine, an extreme case of food insecurity, is a function of a massive collapse of food availability, a sort of Malthusian event. In contrast to the Malthusian and demographic approach, in which food insecurity arises as food output is incapable of keeping up with population growth (see MALTHUSIAN MODEL), Amartya Sen (1981) approaches hunger, and most especially how hunger and food insecurity can degenerate into famine, from a micro-economic vantage point and entitlements. Sen is able to show how gross food insecurity may occur without a decline in food availability, and how entitlements attached to individuals through a generalization of the exchange economy – through MARKETS – may shift in complex ways among differing classes, occupational groups and sections of the population.

Sen begins with the individual endowment, which is mapped into a bundle of entitlements, the latter understood as ‘the set of alternative COMMODITY bundles that a person can command’ (1981, p. 46) through the use of various legal channels of acquirement open to someone of his or her position. Such entitlement bundles confer particular capabilities that ultimately underline well-being.

Central to Sen’s account of why hunger exists is the process of transforming endowments into entitlements, so-called E-mapping. The sorts of entitlements that Sen details are rewards to labour, production, inheritance or asset transfer, and state provisioning (transfers), typically through social security and food relief policies (i.e. anti-famine policies, of which the Indian Famine Codes are customarily seen as a model: Dreze and Sen, 1989). Insofar as an individual’s entitlement set is the consequence of E-mapping on the endowment set, entitlements can only change through transformations in the endowment or E-mapping. Hunger and shortage occurs through a collapse or adverse change in endowment or E-mapping, or both (Sen, 1981). Entitlement, in contrast to other theories, ‘draws our attention to such variables as ownership patterns, unemployment, relative prices, wage-price rations, and so on’ (1993, p. 30).

Sen situates hunger, then, on a landscape, irreducibly social of the capabilities that individuals, and potentially classes, may mobilize. By examining mapping as an active and transformative process – how the capacity to labour, or access to land, can generate an entitlement – it dislodges a concern with output per se and focuses on access to and control over food. It offers a proximate sort of causal analysis predicated on what immediate or conjunctural forces might shift such forms of access and control, and permits a social mapping of such shifts to understand who dies or starves (say, artisanal craftsmen versus PEASANTS) and why. Entitlements – the central mechanism in his intellectual architecture – are individually assigned in virtue of a largely unexamined endowment, and are legally derived from state law (ownership, PROPERTY rights, contract). Entitlements necessitate making legitimate claims; that is to say, rights resting on the foundations of POWER (opportunity or actual command) and LAW (legitimacy and protection). A concern with entitlement failure in market circumstances leads Sen to emphasize public action through entitlement protection.
(state-funded famine protection through food for work or public food distribution) and promotion (a public social security net).

Sen’s concern with entitlements, and relatedly the capabilities of individuals, can be extended to better grasp the conditions under which people become food secure. To begin with entitlements themselves, geographer Charles Gore has noted that ‘command over food depends upon something more than legal rights’ (1993, p. 433). Extended entitlements, for example, might include socially determined entitlements (a moral economy, indigenous security institutions), non-legal entitlements (food riots, demonstrations, theft) and non-entitlement transfers (charity). This highlights a rather different way of thinking about e-mapping. First, entitlements are socially constructed (not just individually conferred): they are forms of social process and a type of representation. Second, like all forms of representation, entitlements are complex congeries of cultural, institutional and political practice that are unstable: that is to say, they are both constituted and reproduced through conflict, negotiation and struggle. Entitlements are, then, political and social achievements that are customarily fought over in the course of modernization (in this sense, one can think about the means by which entitlements enter the political arena in the course of the differing routes to modernity). And, third, social entitlements confirm Sen’s unelaborated observation that the relations between people and food must be grasped as a ‘network of entitlement relations’ (1981, p. 159; emphasis added). Hunger or famine-proneness are the products of historically specific networks of social entitlements.

One of the great strengths of Sen’s approach to food and hunger is that entitlements are part of a larger architecture of thinking about development as a state of well-being and choice or freedom. In his language, the capability of a person reflects the ‘alternative combinations of functioning the person achieves and from which he or she can choose one collection’ (1993, p. 3). Functionings represent parts of the state of a person, and especially those things that a person can do or be in leading a life. In seeing poverty or hunger as a failure of capabilities – rather than insufficient income, or inadequate primary goods as in the Rawlsian sense of justice – Sen shows how the freedom to lead different types of life is reflected in the person’s capabilities (see Sen, 1999).

**hybridity** A condition describing those things and processes that transgress or disconcert binary terms that draw distinctions between like and unlike categories of object – such as self/other, culture/nature, animal/machine or mind/body. Hybridity has entered popular parlance through the commercial mobilization of techno-scientific innovations (e.g. the cultivation of hybrid seeds and plants or the proliferation of hybrid vehicles), or cultural innovations such as cyber-culture or fusion music (see Cyborg). As these examples suggest, the mixing of properties ascribed to opposing ontological categories established through academic and everyday use inspires both social anxiety and excitement.

In geography and the wider social sciences and humanities, hybridity has come to be used rather too loosely to mean any number of different kinds of mixing, such as the notion of ‘hybrid methods’ – which means little more than combining qualitative and quantitative methods in the conduct of research, or what used to be called multi-method approaches. Such usages tend to treat hybridity as an intrinsically desirable quality or strategy. More theoretically or philosophically rigorous explorations of hybridity are associated primarily with two bodies of work: (i) cultural studies (see cultural turn) and identity politics, particularly in the field of post-colonial studies (e.g. Bhabha, 1994; see post-colonialism) and (ii) science and technology studies and posthumanist politics (e.g. Latour, 1993).

In the case of post-colonial studies, hybridity is associated with the interrogation of those contact spaces in which cultural differences are contingently and conflictually negotiated (see Pratt, 1992; cf. transculturation). In the case of science and technology studies, it is enrolled as a device to negotiate the temptations of the ‘one plus one’ logic or ‘mixture of two pure forms’ that pervade binary and dialectical modes of analysis of nature–culture relations (see Whatmore, 2002a). The problem here, as Bruno Latour suggests, is that:

Critical explanation always began from the poles and headed toward the middle, which was first the separation point and then the conjunction point for opposing resources . . . In this way the middle was simultaneously maintained and abolished, recognised and denied, specified and silenced . . . How? By conceiving of every hybrid as a mixture of two pure forms. (1993, pp. 77–8)
HYPERSPACE

As many, particularly feminist, scholars working in philosophy and science and technology studies make clear, the importance of hybridity in these terms is that it insists that questions of social justice cannot be understood in terms of human relations or reasoning alone, and invites ethical and political projects that re-frame these questions in terms of the more-than-human company of bodies, technologies and forces implicated in, and consequential for, the conduct of social life.

**Hypothesis**  A provisional idea requiring further assessment to test its merit. The etymological origin is from the Greek meaning 'to put under, suppose'. Within geography, the formalization of hypotheses was closely associated with the quantitative revolution, in which the 'supposed' was a scientific statement capable of empirical testing using formal statistical techniques (see also deduction).

In its early use, however, 'hypothesis' meant an imagined idea, with only a distant connection to the real. In 1616, Cardinal Bellarmine (1542–1621) warned Galileo Galilei (1564–1642) not 'to hold or defend' the idea of a heliocentric solar system, but to treat is as a 'hypothesis', not reality. And a similar sense was given to the term when Sir Isaac Newton (1643–1727) said about his theory of gravity: 'I feign no hypotheses' – that is, his work was based on observation and experiment, not speculation. By the nineteenth century, in contrast, the use of hypotheses was increasingly seen as an integral part of the very practice of science – not at odds with it, as Newton implied. Hypotheses were where science began; with interesting but as yet unproven ideas that stemmed from scientific theory or models. Whether hypotheses were accepted depended upon the criteria applied. Criteria have included: simplicity (the capacity to minimize new explanatory entities); scope (the power to maximize the domain of application); fruitfulness (the capability to generate future hypotheses); fit (the compatibility with other hypotheses); and, perhaps most important, empirical fidelity (the ability to match the facts).

This last criterion was taken up and formalized within the discipline of statistics from the late nineteenth century. In the late 1920s, the statisticians Jerzy Neyman (1894–1981) and Egon Pearson (1895–1980) set out what was to become the standard framework for statistical hypothesis testing that proved so influential in geography. They provided step-by-step procedures stipulating how to frame a hypothesis and how to assess its empirical merit rigorously and precisely. Formulating the *null hypothesis* was step one. Accepting the conservative supposition that it is better to assume that one is wrong rather than right, the null hypothesis stated the opposite of what one believed to be correct. The remaining steps then defined what was necessary in order either to reject or accept the hypothesis for the specified level of statistical significance.

The first widespread use of the Neyman–Pearson procedures for statistical hypothesis testing in geography occurred in the mid-1950s, at the start of the quantitative revolution. This transformation of the geographical agenda into spatial science was also associated with the introduction of formal theory, which generated a plethora of hypotheses to be tested. Newman (1973, p. 22) reports that in 1971, at the height of the Quantitative Revolution, 26 per cent of all papers published in the top three American geographical journals were concerned with hypothesis testing. That seems impressive, but Newman doubted whether many of the authors understood what they were doing, and whether they were doing it correctly. The point became moot, however, as human geographers increasingly abandoned formal hypothesis testing, and the very vocabulary of a hypothesis. But they have never lost sight of the importance of 'imagined ideas'.

**Hyperspace**  Hyperspace has four or more dimensions. Geographical tradition privileges location and three (Euclidean) dimensions: \( (x, y, z) \) or (Easting, Northing and height)(see euclidean space). Yet, it is rarely just *where* something happens that is important but also *when*, giving a fourth dimension: time. Space–time is therefore a hyperspace that becomes more complex (e.g. to visualize) if variables recording *what* happened (or what is found) are treated as further dimensions of the space. The literary critic Frederic Jameson (1991, pp. 38–44) famously described multi-dimensional ‘hyperspace’ as the characteristic spatiality of postmodernity that disrupts and exceeds conventional modes of representation.

iconography The description and interpretation of visual images in order to disclose and interpret their hermetic or symbolic meanings; a hermeneutic practice, closely paralleled by semiotics in linguistic studies. Initially applied to religious icons and painted images, and theorized as a methodology within Renaissance art history by the cultural historian Erwin Panofsky, iconography was initially introduced into human geography by Jean Gottmann (1952) alongside ‘movement’ as one of two counterposing forces structuring the political geography of nations: the latter acting to integrate territories, and the former to separate them through local allegiances. While this formulation acknowledged a political efficacy on the part of cultural symbols, its impact on geographical study was limited, and only decades later was the symbolic significance of national icons such as landscapes, paintings, buildings and monuments subjected to more systematic iconographic analysis by geographers and others (Daniels, 1993; Schama, 1995).

In contemporary human geography, iconography is principally used as a method of landscape and map interpretation (Daniels and Cosgrove, 1988; Harley, 2001b). Landscapes, both on the ground and in their representation through various media such as maps, painting and photography, can be regarded as visible deposits of cultural meanings (see also cartography, history of; visual methods). The iconographic method seeks to address these meanings through describing the form, composition and content of such representations, disclosing their symbolic conventions and language, and interpreting the significances and implications of their symbolism by re-immersing landscapes in their social and historical contexts. Successful iconographic interpretation requires close formal reading, broad contextual knowledge, interpretative sensitivity and persuasive writing skills: it reveals human landscapes as both shaped by and themselves active in shaping broader social and cultural processes, and thus possessed of powerful human significance. Geographical iconography today accepts that landscape meanings are unstable over time and between different groups, always negotiated and contested, and thus political in the broadest sense. Through this recognition, a connection may be made in terms of politics between current geographical uses of iconography and Gottmann’s original formulation. This is exemplified by the significant body of work on landscapes, monuments, spatial images and the expression and performance of identity that has been produced by geographers since the early 1990s (see, e.g., Whelan, 2003).

ideal type An operational construct originally proposed by the sociologist Max Weber (1864–1920) as a way of exposing the essentials of a situation to analysis for particular purposes: ‘An ideal type is formed by the one-sided accentuation of one or more points of view and by the synthesis of a great many diffuse, discrete, more or less present and occasionally absent concrete individual phenomena, which are arranged according to those one-sidedly emphasized viewpoints into a unified analytical construct.’ The ideal type is ‘ideal’ in the sense of ‘idealized’: it is always a partial characterization of a phenomenon that, by emphasizing particular features and ignoring others (marginalizing them, holding them constant), draws out what the analyst regards as particularly important. It is thus purposive, an abstraction, and ideal means ‘pure’ or ‘abstract’, with other elements stripped away (cf. model).

idealism A humanist philosophy based around the belief that the world is constructed through the human mind (see humanism). Idealism’s assertion that ‘all reality is in some way a mental construction so that the world does not exist outside its observation and representation by the individual has long been posed against the positivistic epistemology and its emphasis on objective evidence’ (Johnston, 1986, p. 55). Idealism was set in opposition to materialism, which privileged matter, rendering the import of mind or spirit secondary, dependent or invisible. In geography, this is most closely associated with
the work of Leonard Guelke, who drew on historian R.G. Collingwood’s ‘historical idealism’, which insisted that ‘all history is the history of human thought’. Idealism in geography regarded its aim as being one of ‘rethinking the thoughts behind the actions’ (Cloke, Philo and Sadler, 1991, p. 70; emphasis in original). In a challenge to what he considered to be over-theorization of contemporary human geography, Guelke’s idealism required a move from concern with the theories that geographers held about the world and its workings to a primary focus upon the theories used by human beings acting in the world. For Guelke, a geographer’s role is to understand the theories lying behind action that essentially make up human agency. As he put it, the ‘intention behind an action can be regarded as the source of its power and theory in it can be considered to be the guidance system’ (Guelke, 1974, p. 197).

Any insistence of the theory-neutrality of academic research is problematic. Moreover, Guelke’s vision of geography suggests a world in which humans act ‘rationally’ on the basis of how they conceptualize their worlds. Thus, in many respects Guelke’s idealism is an extension of behavioural geography, rather than having a close association with the philosophically charged recovery of agency in (most) humanistic geography (which focused upon notions of feeling, emotion and meaning). Guelke viewed human agency as being based upon intentional decisions, ignoring both the constraining and enabling effects of economic structures and cultural discourse. Geographies influenced by psychoanalytic theory have challenged the possibility of individual agents knowing their motivations and have turned to the effects of the unconscious.

The concern of new cultural geographers with discourse and representation, although very different conceptually from Guelke’s idealism, have nevertheless generated new debate around idealism, with both Marxist and social geography expressing concern about the lack of attention given to issues of the material (see Mitchell, 1995; Duncan and Duncan, 1996; Philo, 2000a). Theorizations of the body as an inscriptive surface where the material and discursive articulate have sought to transcend the idealism-materialism debate (Nast and Pile, 1998). jsh

**identity** The origins of a term that is increasingly used throughout the social sciences are somewhat obscure, but its shifts reflect changing conceptions of the human subject in the discourses of modern and late-modern thought. With its inheritance of Renaissance humanism, which posited Man (sic) as the ‘measure of all things’, and the dramatic changes inaugurated by the Protestant Reformation, the enlightenment is usually identified as the context within which the identity of the modern subject definitively emerges. Based on a conception of a self-sustaining entity, possessed of the capacity of conscious reason and whose internal ‘centre’ was seen as essentially fixed – continuous or ‘identical’ with itself across time – the Enlightenment aligns identity to a decisive form of individualism. Prioritized in the seventeenth century by René Descartes (‘I think, therefore I am’), John Locke (who equated individual identity with the ‘sameness of a rational being’; see Locke, 1667 [1690]) and attenuated through the nineteenth and twentieth centuries, the individual is positioned as the author of historical development, his identity seen as the sovereign source from which all social laws and categories of knowledge are derived.

The changing formations of modern society, and the development of sociology that sought to understand them, provided the first critique of this model. Locating individual identity within group processes and submitting it to the dynamics of collective and contractual norms, sociologists such as G.H. Mead (see symbolic interactionism) argued the ways in which identities are positioned within wider social relations and, conversely, function to sustain wider social structures. While such theories of socialization clearly break with the autonomy of the humanist self, they nonetheless continue to uphold the principle of a stable identity; the relation between the individual and society being an interaction between two reciprocal, but nonetheless distinct, entities.

A key revision that resolutely displaced the Cartesian and sociological subject was the reconstruction of Marxist social theory in the late 1960s. For the Marxist structuralist Louis Althusser (1970), the privileging of social formations did not just invert the relations between the individual and society, but jettisoned subjective agency from the processes of history, the concerns of ethics and the terms of philosophy itself (see Marxism; structuralism). From this perspective, identity is not
only conditional, lodged in contingency, but divested of any transcendental authority it becomes little more than the effect or ‘bearer’ of a social structure. ‘Self-hood’ thus does not derive from any faculty held in the mind, but via the mechanism of ‘interpellation’; that is, by those ideological processes that on the one hand ‘speak to us’ or ‘hail us into place’ as the social subjects of particular discourses and, on the other, produce us as subjects that can ‘speak’ and can be ‘spoken’. To this novel understanding of identity must be added the impact of Freud on twentieth-century Western thought. Indeed, if Freud’s original ‘discovery’ of the unconscious put paid to the humanist project of the self-knowing individual, later psychoanalytic theorists, such as Jacques Lacan, insist on identity as unresolved and irresolvable: not something that evolves organically or intentionally from inside the core of cognitive being, but via a struggle that charts the infant’s difficult entry into various systems of symbolic orders, including language, culture and sexual difference. For Lacan, the agony of this ‘entry’ not only leaves the subject always divided in itself (the perception of wholeness being, for Lacan, as for Althusser, only an ‘imaginary’ or fantasized pleasure), but maintains this improper fit as an initial and continuing experience. Psychoanalytically, then, we should speak not of identity as something achieved or achievable, but of identification as an always imaginary search for the image of a resolved self (see Psychoanalytic Theory).

With the de-centred subject located as the unstable core of modern and late-modern thought, identity is not only exposed as a social and psychic process, but is posed as a political problem (Pile and Thrift, 1995). With the growth of cultural studies in the 1970s, it is deployed not only a critical tool useful in the analysis of cultural forms, but as the social subjects of particular discourses and, on the other, produce us as subjects that can ‘speak’ and can be ‘spoken’. To this novel understanding of identity must be added the impact of Freud on twentieth-century Western thought. Indeed, if Freud’s original ‘discovery’ of the unconscious put paid to the humanist project of the self-knowing individual, later psychoanalytic theorists, such as Jacques Lacan, insist on identity as unresolved and irresolvable: not something that evolves organically or intentionally from inside the core of cognitive being, but via a struggle that charts the infant’s difficult entry into various systems of symbolic orders, including language, culture and sexual difference. For Lacan, the agony of this ‘entry’ not only leaves the subject always divided in itself (the perception of wholeness being, for Lacan, as for Althusser, only an ‘imaginary’ or fantasized pleasure), but maintains this improper fit as an initial and continuing experience. Psychoanalytically, then, we should speak not of identity as something achieved or achievable, but of identification as an always imaginary search for the image of a resolved self (see Psychoanalytic Theory).

With the de-centred subject located as the unstable core of modern and late-modern thought, identity is not only exposed as a social and psychic process, but is posed as a political problem (Pile and Thrift, 1995). With the growth of cultural studies in the 1970s, it is deployed not only a critical tool useful in the analysis of cultural forms, but as an active site of conflict and resistance within social relations fractured by divisions of gender, class and race. Energized by the ferment of ideas produced by the late 1960s – the counter-culture, civil rights, feminist, anti-colonial and anti-war movements (see feminism) – the ‘politics of identity’ emerged to mobilize new, and hitherto untheorized, individual and collective possibilities. While very different kinds of identity were examined (from working-class to sexual and gendered identities; from racial to generational identities), such analyses were determinedly committed, with a distinctively autobiographical, reflexive and strategic charge. The dialogue between identity and the ‘politics of location’ was to become key, especially within debates of how affective investments in the idea of a home(land) relate to the resources of history, language and culture in the production of subjective and collective allegiance. Thus various theorists (Gellner, 1983; Renan, 1990 [1882]; Balibar, 1991b; Hall, 1992a) explored the ways in which identities relate to the (relatively modern) invention of the nation, which they invite us to read less as a political or territorial site than as the particular expression of cultural tradition; as an articulation of communal belonging sustained as much by myths of origin and homogeneity as it is by the supposed continuities of character, value and custom. From this perspective, national identity is decisively not a primordial gift of birth, nor even a coincidence of geographical location, but the willed incorporation into an ‘imagined community’ (Anderson, 1991 [1983]), a fiction continually formed and transformed by the narratives, and counter-narratives, of its telling.

By the late 1980s, this account was given fresh prominence with the explosion of post-colonial theory (see Post-colonialism), which sought, amongst other things, to deconstruct the unity of the sovereign self written into European knowledge, theory and history. If at one end of the spectrum modern Western nations have produced stories of familial membership in order to negotiate internal contradictions (Matless, 1988; Cresswell, 1996) or exercise forms of territorial expansion (Daniels, 1993; Driver, 2001a), at the other end conscious assertions of identity have been mobilized as a strategy of resistance for those dispossessed by the legacy of empire (Blunt and McEwan, 2002). Yet – as in fantasies of the ‘whole’ self of which Lacanian psychoanalysis speaks – this often releases a regressive desire to reclaim the (lost) integrity of a ‘local’ or national particularity as a way of negotiating the competing pressures of existent and emergent multiplicities. In this context, identity means not only the aspiration to Selfhood, but the assumption of a fictive Otherness. Having no positive meaning, but positioned within a field of differences, identity thus entails discursive work: the binding and marking of symbolic boundaries, the defining of identity by what it produces as its negative excess or ‘constitutive outside’. The crucial point, however, is not simply that identity derives its distinction from what it is not. More precariously, the ‘Other’ returns to breach the foreclosure that we prematurely call ‘identity’ (Butler, 1990).
At present, processes of migration, transnationalism and diaspora place identity (or the project of identification) firmly on the theoretical agenda. In the midst of such mobilities – as much a geographical and historical reality as a theoretical benefit – new spatial metaphors of the ‘out of place’ and ‘in-between’ render identity as a performance of ambivalences, doublings and dissimulations. Various theories of the post-colonial (Said, 2003 [1978]; Spivak, 1988; Bhabha, 1990a) have all sought a more complex, non-binary mode of identity, replacing neat national and ethnic divisions with the more fluid terms of ‘translation’, hybridity and transgression, and using these as critical strategies for destabilizing the power, and polarities, of Western thought. As a counter-current, however, the resurgence of neo-nationalisms (Eastern Europe post 1989), the rise of religious absolutisms (from India, to the Middle East to the USA) and a renewed rhetoric of civilizational differences (the image of a ‘clash of civilizations’) speak directly of an anxiety at the core of our contemporary selves. Indeed, if a hardening of identities is one symptom of the contradictions of the local and the global in postmodernity, from another perspective the national frame in which people have conventionally positioned themselves has been eroded by a new social order in which the homogenizing effects of global markets has reconfigured identity as a ready-to-buy, consumer option.

All of this charges identity with questions of our present and future political and ethical practice. While recognizing its fictive nature, the disruption of conventional paradigms of social experience and analysis (the nation, ideology, gender, race, class) heralds different possibilities of identification, placing new emphasis on subjective agency in its relational negotiations and improvisations. At this point, as Stuart Hall puts it, the question is not about ‘who we are’ or ‘where we have come from’ so much as ‘what we might become, how we have been represented and how that bears on how we might represent ourselves’ (Hall and du Gay, 1996).

Suggested reading

ideology Ideology originally referred to a ‘science of ideas’, proposed by French rationalist philosophers at the end of the eighteenth century. It is now more widely used to refer to any system of beliefs held for more than purely epistemic reasons. Some theories of ideology are neutral when it comes to accounting for the role of ideas and beliefs in social life. Others involve normative claims about how knowledge and belief function epistemologically to reproduce power-relations. In this second set of theories, ideology is understood as a distorted, inverted, upside down or false view of reality. In this usage, ideology is therefore implicitly or explicitly counterposed to some mode of knowing that sees reality in a true and accurate way. The most influential source for this second type of understanding is Marxism.

Despite never having been clearly worked through in his own work, ideology is arguably Marx’s most powerful bequest to modern social theory. In the German ideology of 1845, Marx and Engels argued against idealist philosophies that saw ideas as the prime movers of historical change (see IDEALISM), asserting instead that ‘social being’ determined people’s ‘consciousness’. This is a basic axiom of materialist analysis (see HISTORICAL MATERIALISM). They also argued that in class-divided societies such as those of CAPITALISM, the ruling ideas would be those of the ruling class, since they owned and controlled the means for producing and circulating the knowledge, beliefs and values through which people made sense of their own experiences. In Marx’s early work, this ideological determination of people’s consciousness is theorized in terms of the alienation of the working class, who come to see social relations in inverted form. The argument was subsequently later reformulated as commodity fetishism. In 1867, Marx argued in Capital that under generalized capitalist commodity production, the social dimensions of human labour and interaction take on the appearance of free-standing objects, and commodities take on apparently magical qualities independent from the labour processes that produce them. Commodity fetishism is a theory of how people come to misrecognize reality through the medium of distorted appearances. This kernel of a mature theory of ideology was further refined in 1923 by György Lukács, in History and class consciousness, with the concept of reification, whereby people appear to each other as things rather than as active agents of historical processes, which he held to be a form of false consciousness.

The epistemological understanding of ideology as a generalized system of misrecognition in the interests of capitalist reproduction was systematized into models of base and superstructure, in which economic processes are
seen to be the prime movers shaping other aspects of social formations, such as law, religion or general modes of consciousness. The vast Marxist literature on ideology is beset by the recourse to functional explanation (see FUNCTIONALISM), drawing of loose analogies, and imputing of structural isomorphisms between economic patterns and behaviour and belief. It is not too strong to suggest that the Marxist theory of ideology is ‘partly anecdotal, partly functionalist, partly conspiratorial, and partly magical’ (Elster, 1982a, p. 199).

Marxist theories of ideology share two features: a formal aspect, in which ideology is understood to be a medium for the inversion or obscuring of reality; and a content, in which ideology is held to function in the interests of particular classes, by presenting their particular interests as if they were the interests of all classes. In both respects, there is a presumption that ideology is politically effective by making social relations and historical processes appear natural, inevitable, objective or a-historical. This is the strongest legacy of the Marxist heritage of theories of ideology, which lives on in a widespread assumption that the task of critical social science is the exposure of naturalized, de-historicized, objectified appearances as historical products and social constructs (see CRITICAL THEORY).

A recurrent theme in Western Marxism from the 1920s onwards was how to understand the means by which capitalist exploitation was legitimized through the active consent of those who were the main sources of economic value and the primary victims of injustice. The prevalence of this problem of reproduction helps account for the flourishing of Marxist cultural theory (Anderson, 1976). The absence of widespread political upheaval against capitalism was identified as a failure at the level of culture, attributed to the operations of ideology. In short, sophisticated theories were developed to explain capitalist reproduction on the assumption that ‘people must have been got at’ (Sinfield, 1994, p. 22). Some of Marxism’s most important contributions emerge from this explanation of capitalist reproduction as a problem of culture and ideology. These include a shift away from focusing on false consciousness towards a consideration of the unconscious dynamics of personality formation, in the work of Herbert Marcuse for example; Theodor Adorno and Max Horkheimer’s seminal account of the culture industries; Antonio Gramsci’s account of cultural hegemony; and V.N. Volosinov’s account of the inherently social qualities of the linguistic sign. The development of Marxist theories of ideology relied heavily on non-Marxist traditions such as psychoanalysis, Weberian sociology and semiotics. For all the sophistication of this tradition, it led to a curious ‘blindspot’ in Western Marxism, which came to think of cultural media such as radio, television or film primarily as ideological devices, neglecting to analyse these practices as sources for the production and distribution of surplus value (Smythe, 1978).

The nemesis of Marxist theories of ideology came in the figure of the avowedly Marxist philosopher Louis Althusser. Combining Lacanian psychoanalytic theory with Gramsci’s account of hegemony, Althusser (1971) recast the concept of ideology in ways that still resonate in a range of cultural theory. He argued that ideology was not something that people could be liberated from, but rather, a constitutive dimension of all social formations: ideology was the mechanism through which individuals were made into subjects. The formation of subjectivity was legitimized through the practices embodied in institutions such as churches, schools and universities. These he called Ideological State Apparatuses (ISAs). For Althusser, ideology referred to the ‘representation of the imaginary relationships to their real conditions of existence’. Imaginary in this formulation does not mean false or unreal. It refers to the idea that this relationship is always, necessarily, mediated by way of images. In short, Althusser claimed that misrecognition was the constitutive mechanism of subjectivity in all societies, not just under capitalism; therefore it was not something that people could be liberated from.

Althusser’s account of ISAs laid the basis for a generalized analysis of cultural practices in terms of practices of subject-formation rather than consciousness. The notion of ideological subjectification in ISAs served as a crucial way-station for the development of feminist theories of ideology, psychoanalytical theories of sexuality, and for the eventual supervision of ‘ideology’ by concepts of discourse, DISCIPLINARY POWER, GOVERNMENTALITY and other notions drawn from Michel Foucault’s work (Barrett, 1991). The class content of ideology that Althusser took for granted was filled by other identities: ethnicity, gender, race and sexuality. The assertion that subjectivity was formed in ISAs was instrumental to the recognition that that struggles within civil society were a crucial dimension of counter-hegemonic political struggles (it also tended to flatter academics’ sense of their own centrality to these struggles).
The traces of Althusser’s account of ideology are still evident in theories of culture, discourse, governmentality and hegemony, even if the concept of ideology is rarely used in a strong analytical sense any more. There are three such traces of ideology in cultural theory, post-Marxism and post-structuralism: an emphasis on practices of subject-formation; an emphasis on the cognitive dimensions of this process, understood in terms of the naturalizing or de-historicizing of contingent relationships through the medium of representations; and an emphasis on how macro-level processes of subordination, exploitation and oppression are reproduced through this micro-level process of subject-formation. These related conceptualizations are given a geographical inflection by analysing the ways in which spatial forms (such as boundaries, scale relations or place identities) are inscribed in the representations that are supposed to function as mediums for subject-formation. The primary emphasis of post-Marxist, post-structuralist theories of discourse and hegemony remains on the ways in which people’s subjectivities are socially constructed (see social construction). Human geographers have largely ignored the more productive turn towards analysing ‘ideology’ in terms of rhetoric, focusing on the relationships between active, socially constructing human subjects negotiating various argumentative dilemmas in everyday situations (Billig, 1996).

Marxist theories of ideology have not fared well in recent social theory. Abercrombie, Hill and Turner (1980) challenged the idea that ideology was a crucial factor in the reproduction of capitalism, calling attention to the degree to which this assumption depended on a functionalist view of society as a tightly integrated totality, whose parts contribute to the better operation of the whole. Criticisms of this sort have led to the revival of more neutral accounts of ideology. Thompson (1990) defines ideology as any system of signification that facilitates the pursuit of particular interests by a social group. Mann (1986) defines ideology as one of four sources of social power (along with economic, political and military sources), involving the mobilization of values, norms and rituals. In this sense, ideology is not false, although it does involve holding beliefs that surpass experience. ‘These sorts of definitions see ideology in general as a ubiquitous feature of human affairs, while particular ideologies can be analysed for their practical effects and normative implications. Nevertheless, all concepts of ideology remain dogged by the problem that while it may be plausible to assume that ideas are produced with certain intentions to influence and effect people, it is conceptually and empirically very difficult to account for just how these intended purposes actually come off successfully at all.

Theories of ideology, and their successors, are faced with two fundamental limitations. First, they emphasize the cognitive and epistemological dimensions of knowledge and belief, and assume that non-cognitive grounds for belief are at least suspect, if not false. This is an impoverished view of what it is to be a functioning human being, and it leads to a deeply problematic understanding of the politics of critique (Hanssen, 2000). Second, theories of ideology and their analogues face a persistent problem in justifying and accounting for their own epistemological claims (see epistemology). The persistence of modes of ‘ideological’ problematization in academic analysis might even be interpreted as a symptom of scholasticism – the process by which the untheorized conditions of separation, distancing and detachment that enable academic reflection are projected on to objects of critical analysis (Bourdieu, 2000).

Idiographic Concerned with the unique and the particular (cf. nomothetic). The term originated at the end of the nineteenth century when two German philosophers, Wilhelm Windelband and Heinrich Rickert, made a famous distinction between the idiographic and the nomothetic sciences that, so they claimed, entitled history (by virtue of its central concern with the unique) to be regarded as radically different from other forms of intellectual enquiry (see KANTIANISM). Their arguments were challenged by other philosophers, but they made a forceful entry into geography in the middle of the twentieth century through the Hartshorne–Schaefer debate over exceptionalism, when traditional regional geography was seen – in parallel with history – as essentially idiographic and not directed towards generalization. These claims were intensified during the quantitative revolution, which was widely advertised as re-establishing geography within the mainstream of the sciences as a nomothetic system of knowledge ‘after the lapse into ideography’ (Burton, 1963). The term is rarely used today, and the idiographic/nomothetic binary has largely disappeared from most framings of geographical
enquiry, but the issues it signals continue to animate geographers concerned with articulating theoretical claims with empirical particulars (see Burt, 2006).

image  ‘According to ancient etymology the word image should be linked to the root imita-  

tan’ (Barthes, 1977). Thus we go to the heart of a problem first posed in Pliny’s Naturalis  

Historia, later refined by Renaissance aestheti-  
cians and subsequently up-ended by modernists  
and postmodernists alike. Is the image (eikon) a particular kind of medium through  

which the world is most persuasively relayed  

to our understanding? Or is the image a  

graphic language that ‘invisibly’ encodes  

whole systems of value – a history, geography,  
a morality, an epistemology? Whatever the  
case, to consider the image is to be aware of  
a trick of consciousness: an ability to see  

something as ‘there’ and as ‘not there’ at the  
same time; to appreciate that while the image  
might duplicate reality, it is itself not ‘real’.  

With the status of the mimetic challenged by  

both the conceptualism of twentieth-century  
Western art and the critical charge launched  
by the textual or ‘cultural turn’ from the  
mid-1970s onwards, the image is now most  
commonly considered as a cultural encoding  
of a particular kind: as visual mode that in-  

volves the intervention of language and thus  
relies on those arbitrary, though convention-  
alized, signs to be accessed and read cor-  

rectly. The image, in this sense, is what  

displays itself most and hides itself  

best. Accordingly, much contemporary geo-  

graphy (Daniels, 1993; Duncan and Duncan,  
1992; Cosgrove, 1998 [1984]) has focused on  
the ideological force and function of the  
image; the ways in which by rooting itself in  
the apparent obviousness of the visible, the  
image effectively conceals the practices of  
its making.

But the power of the image does not consist  
merely in being a vehicle for interrogating  
what it occludes or for interpreting the  
relationship between expressed visual content and  
external or referential context. The image also  
interprets us. It does so in the sense that our  

ttempts to understand the precepts and prac-  
tices within we make our critical, political and  
epistemological choices are organized by tacit  
images, by a panoply of visual structures (e.g.  
the photographic ‘freeze’, cinematic mobility,  
digital malleability and its global relay)  
through which we create our orders of time,  

space and subjectivity (see film; vision and  
visuality).

What emerges is a vast aggregate of things  
that go by the name of the image, deputized  
across a variety of methodologies, institutions  
and disciplines. Thus while some contempo-  
rary geographers have been concerned with the  
encoding and deciphering of pictorial or tech-  
tchnological images (e.g. landscape painting or  
photography), others have examined imagery  
in its proper or literal sense (graphic or plastic  
artefacts such as maps, diagrams, monuments  
and buildings). More abstractly, geography  
has considered various metaphorical exten-  
sions of the concept at work within literature  
(the image as ornamented language in travel-  
writing, for example), epistemology (the image  
as idea in the ‘eye of the mind’), physics (the  
image in optical theory), psychoanalysis (the  
image as dream, memory, fantasmatas and  
even, conceivably, within the possibilities of  
biotechnology (the genetic code-as-image).  

While it is impossible for so many category  
definitions to settle into comfortable coexis-  
tence, contemporary debates about the image  
share a degree of critical consensus: a rejection  
of truth as a matter of accurate imaging and an  
understanding, instead, of its cultural signifi-  
cance, historical circumstance and its power  
as epistemological constituent. All images,  
whether visual, graphic, textual, perceptual or  
psychic, are thus viewed as reflective medi-  
ations of objects, concepts and affects. Ac-  
cordingly, all are disorderly and riddled with  
error. The misconception, then, is to think  
that we can know the truth about the world  
by knowing the right images of it. But the  
other misconception is to think that we can  
know anything about the world without im-  
ages. One need not favour the postmodern  
conviction of reality as a depthless simula-  
crum (Baudrillard, 1983), nor want to oppose  
such cynicism with a more corporeal and per-  
formative approach (see performativity), to  
acknowledge that since the image is all we have  
to work with, we need to regard it not only as a  

site of semiotic or perceptual convention but  
as a starting point for a dialogue with convention  
that leads us to its limits. This includes investi- 
gating what might lie outside or beyond the  
image, as well as thinking about the relation  
of the image to the non-image, of vision to not-  
seeing, to invisibility and even to blindness. JD

imaginative geographies Representations  
of other places – of peoples and landscapes,
cultures and ‘natures’ – that articulate the desires, fantasies and fears of their authors and the grids of power between them and their ‘Others’. The concept is not confined to ostensibly fictional works. On the contrary, there is an important sense in which all geographies are imaginative: even the most formal, geometric lattices of spatial science or the most up-to-date and accurate maps are at once abstractions and cultural constructions, and as such open to critical readings.

The concept was originally proposed by the Palestinian/American literary critic Edward Said (1935–2003) in his influential critique of Orientalism (Said, 2003 [1978]; see Gregory, 1995a). His emphasis on power (and in particular colonial power) was alien to the concepts of environmental perception and mental maps then current in behavioural geography, and underscored the radical ‘non-innocence’ of representation. In some measure, Said’s formulation anticipated ideas of situated knowledge: he was concerned to disclose the privileges that European and American authors typically claimed when representing other cultures, to chart the asymmetric grid of power within which (as he put it) ‘the West’ watches, ‘the East’ is watched, and hence to criticize the partialities of their constructions.

Said’s emphasis on viewing, watching, looking, observing – on vision and visuality – drew attention to the cultural construction of the gaze. While Said’s critique of Orientalism was shot through with visual metaphors, the imaginative geographies with which he was centrally concerned were textual. Human geographers have been drawn to both the textual and the visual image, however, including art forms such as film and photography (Schwartz and Ryan, 2003), and they have drawn attention to viewing as an embodied, vitally sensuous practice (Martins, 2000). Unlike the other constructs of behavioural geography, therefore, none of these imaginative geographies are seen as the product of purely cognitive operations. As cultural constructs, their images are animated by fantasy, desire and the unconscious, and indeed the very idea of an ‘imagination’ has been extended through geographies indebted to various forms of psychoanalytic theory (Pile, 1998). These images carry within them comparative valorizations – what Said called a ‘poetics of space’ – by means of which places are endowed with ‘figurative value’. Such constructions also involve a poetics (and a politics) of nature, and there has been considerable interest in recovering imaginative geographies of other ‘natures’ as well as other cultures. At the limit, these distinguish a ‘normal’, temperate nature from other, intemperate natures and install their own cultural subtext about those who inhabit such ‘unnatural natures’ (Gregory, 1995b; Siobh, 1998; see also tropicality).

Said claimed that these figurative values enter not only into the production of ‘otherness’ but also into the identity-formation of the viewing subject in a complex dialectic. Imaginative geographies thus sustain images of ‘home’ as well as ‘abroad’, ‘our space’ as well as ‘their space’: ‘Imaginative geography and history help the mind to intensify its own sense of itself by dramatizing the distance and difference between what is close to it and what is far away’ (Said, 1978, p. 55). Hence Orford (2003) showed that imaginative geographies are regularly mobilized to separate the space of ‘the international community’ from the space of those facing security crises, so that intervention is always after the event and constructed as selflessly humanitarian; she argues that this separation is achieved through tactics of localizing and distancing (‘their space’) that work not only to legitimize the actions of the global North as so many virtuous efforts to find a solution, but also in many cases to obscure the active involvement of its international actors in the generation of the crisis. Similarly, Graham (2006) contrasts the imaginative geographies that have been used to separate homeland cities from ‘terror’, ‘target’ or Arab cities during the ‘war on terror’, even as they are also being integrated through techno-science ‘into a single, transnational battlespace’. Studies like these show why Gregory (2004b, p. 256) concludes that imaginative geographies are doubled spaces of articulation whose ‘inconstant topologies are mappings of connective dissonance in which connections are elaborated in some registers even as they are disavowed in others’.

‘Dramatization’ is not the same as ‘falsification’, however, and Said’s discussion undercuts the distinction between ‘real’ and ‘perceived’ worlds on which behavioural geography depended. This is the most complicated and contentious part of Said’s argument. There are certainly passages where he contrasted what he called ‘positive geographies’ with imaginative geographies produced under the sign of Orientalism. And yet, if imaginative geographies are ‘fictions’ in the original Latin sense of fictio – something made, something fabricated – this does not mean that they are
necessarily without concreteness, substance and, indeed, ‘reality’. On the contrary, imaginative geographies circulate in material forms (including novels, paintings, photographs and film; intelligence reports, academic geographies and popular TRAVEL WRITING; and collections and exhibitions) which become sedimented over time to form an internally structured and, crucially, self-reinforcing archive. This supplies a ‘citationary structure’ for subsequent accounts that is also in some substantial sense PERFORMATIVE: it shapes and legitimizes the attitudes and dispositions, policies and practices of its collective audience, so that in this way imaginative geographies spiral into and out of a sort of cultural paradigm of ‘otherness’ that has the most acutely material consequences.

Imaginative geographies thus act to both legitimize and produce ‘worlds’. The circulation and sedimentation of imaginative geographies produces a sense of ‘facticity’ and hence of authority: the repetition of the same motifs becomes a taken-for-granted citation of Truth (Vanderbeck, 2006). In some cases, imaginative geographies work to domesticate other spaces and hence validate (for example) colonial dispossession: thus Carter’s (1987) project of an avowedly spatial history showed how the LANDSCAPE of AUSTRALIA was brought within the horizon of European intelligibility through a series of explicitly textual and cartographic practices. In other cases imaginative geographies articulate spaces of (radical) difference, but here too, through their implication in systems of power and practice, they may be read as so many PERFORMANCES of SPACE. Thus Gregory (2004b) distinguished three strategies put to work during the ‘war on terror’ to bring ‘the enemy’ into view within three different spaces: reduced to targets in the coordinates and pixels of an abstract, geometric space; reduced to barbarians attacking the gates of CIVILIZATION from a wild, savage space; and reduced to the inhuman, lodged in a paradoxical space of exception (see EXCEPTION, SPACE OF) wherein their deaths were of no consequence (see also TERRORISM).

Seen thus, imaginative geographies are spaces of constructed (in)visibility and it is this partiality that implicates them in the play of power.

In response, imaginative counter-geographies are deliberate attempts to displace, subvert and contest the imaginative geographies installed by dominant regimes of power, practice and representation. Usually produced from within the targets of representation, they seek to give voice and vision to their subjects and to undo the separations between ‘our space’ and ‘their space’: thus ‘the empire writes back’ and ‘the subaltern speaks’ to undermine the impositions of imperialism and subalternity (Slatter, 1999: see SUBALTERN STUDIES). Testimonies of this sort have a long history, but today they frequently use so-called ‘new media’ to produce new publics: hence Gregory (2009c) explores blogs from Baghdad whose counter-geographies of everyday life contest US political and military imaginaries of Arab cities.

immigration A form of migration that occurs when people move from one nation-state to another. Immigrants change their permanent dwelling place and are therefore distinct from SOJOURNERS, who relocate temporarily, usually for employment-related reasons; immigrants also move voluntarily and are therefore distinct from REFUGEES, who are forced to leave their homes because of persecution. When immigrants settle in a new country without the knowledge and approval of the government in power, they are called ‘undocumented’, ‘illegal’ or ‘unauthorized’ immigrants. Millions of people immigrate each year, and this form of migration is one of the most significant causes of social change in the world today (Clark, 1986; Sassen, 1996).

There have been several episodes of mass migration in history, but the decades following the Second World War have seen the largest population movements of all time. Immigration, in the sense in which the term is used today, began after the creation of nation-states and, until recently, was closely associated with colonization (cf. COLONIALISM). For example, British subjects migrated to the colonies and created SETTLER SOCIETIES; after colonies gained independence, this movement continued in the form of immigration. Others, at first mainly from European countries, joined them and many former colonies, such as Australia, Canada and the USA, consider themselves ‘immigrant societies’ in the sense that the
IMMIGRATION

The overwhelming majority of their citizens are either immigrants themselves or the descendants of immigrants. Until recently, virtually all immigrants migrated towards what they believed to be greater economic opportunities. These historic patterns have changed in the past twenty-five years, in two key ways. First, both source and destination regions have multiplied, and immigration now is more global in scope than at any time in the past (Castles and Miller, 2003). Second, in marked contrast to past periods, a small but highly significant number of today’s immigrants are wealthy. These ‘designer immigrants’ are especially concerned with political issues (i.e. stability) and lifestyle. They are sought by many countries for their entrepreneurial skill and capital, and have significantly changed the way in which immigrants are perceived in the places in which they settle (Skeldon, 1994; Mitchell, 2004a).

According to the influential report of the UN Global Commission on International Migration (GCIM, 2005), there are nearly 200 million people in the world who have been living, for at least one year, outside their country of birth, which translates to roughly 3 per cent of the global population. According to the GCIM (p. 2), ‘The Commission concludes that the international community has failed to capitalize on the opportunities and to meet the challenges associated with international migration.’ In particular, the GCIM concluded that the reception policies of destination countries do not enable immigrants to integrate efficiently.

Immigrants, wherever they settle, are usually culturally different from their receiving societies. Often, they are ‘visible minorities’ (i.e. of a different skin colour than the dominant population). The reception of immigrants varies widely between countries, but three types of responses are typical: isolation, assimilation and pluralism. Some societies believe that immigrants are necessary to fulfil certain functions – for example, when they face labour shortages – but that they should remain separate from the dominant population and, ideally, leave when no longer needed. This was the case, for example, in many Western countries in the period following the Second World War, and it is true of countries such as Japan and Singapore today (Yeoh, 2006). Countries that ascribe to this view make it difficult for immigrants to acquire full legal rights and, especially, citizenship. Others, such as France and, to a more limited extent, the USA, expect immigrants to conform, or assimilate, to a predefined national culture. In this case, full legal rights and citizenship are often granted in stages, in step with the assimilation process. Finally, a few countries, notably Australia and Canada, have enacted legislation enshrining the concept of multiculturalism, a policy that fosters the coexistence of many forms of cultural expression. These countries typically allow immigrants to become citizens quickly and, acknowledging the complexities of identity, allow individuals to hold dual or multiple legal citizenship(s). Note, though, that the differences between these policies are easily overstated, and that countries rarely follow single immigration policies that are applied to all groups equally. Also, recall that the GCIM has concluded, generally, that reception policies are inadequate.

Traditionally, immigration has been analysed in straightforward terms as a push–pull process: people leave a country to escape problems, such as poverty or political conflict, and are drawn to particular places that offer them a better life. In this conception, people are treated as rational individuals who are willing to cast aside their old identities and loyalties and embrace new ones if they believe it is to their advantage. Settlement is seen as a unidirectional, progressive process, where immigrants eventually become indistinguishable from the society that receives them – they become assimilated. This interpretation arose out of the research of the Chicago School in the early twentieth century and continues to affect immigration research. However, recent work, drawing on different understandings of history, culture and identity, offers an alternate perspective. First, migration is seen as a collective process that occurs sequentially and in both directions. Immigrants rarely sever the links between their previous and present places and social contacts, and life in the new country is linked to life in the old (cf. chain migration). As a result, immigrant culture becomes a mélange of practices, and identities are in flux rather than fixed, or in an inexorable progression from old to new. More and more, immigration studies are adopting the view of cultures as diasporic – as scattered, but connected across vast distances. This realization has led to the concept of transnationalism, the idea that many people live in societies that stretch across – and perhaps even transcend – national boundaries (see Appadurai, 1996; Van Hear, 1998).

These new understandings of the immigration process are particularly salient given the
imperialism An unequal human and territorial relationship, usually in the form of an empire, based on ideas of superiority and practices of dominance, and involving the extension of authority and control of one state or people over another. Derived from the Latin word imperium (‘sovereign authority’), imperialism is closely affiliated with colonialism. Both are intrinsically geographical – and traumatic – processes of expropriation, in which people, wealth, resources and decision-making power are relocated from distant lands and peoples to a metropolitan centre and elite (through a mixture of exploration, conquest, trade, resource extraction, settlement, rule and representation), although the latter differs from the former in terms of the intensity and materiality of its focus on dispossession. ‘Imperial’ is used to denote attitudes and practices of dominance befitting an empire.

The term was originally used in the second half of the nineteenth century to describe a state-centred ethos of territorial expansion – epitomized by the imperial partition of Africa between 1885 and 1914 – that involved both aggressive national competition for prestige and a more general rationalization of imperialism as a ‘civilizing mission’. This era of ‘classical imperialism’ drew old and new imperial powers (Britain, France, Portugal and Belgium; Germany, Italy, Japan and the USA) into an expanding and volatile capitalist world system, and two world wars that precipitated the swift disintegration of the sprawling colonial empires that had been built over the previous four centuries (Baumgart, 1982; cf. decolonization). Geography – as both a discipline and wider discourse – forged an intimate relationship with imperialism during this period (cf. geography, history of). Projects of exploration and mapping, geopolitical models and climatic arguments for European superiority and racial difference played especially important imperial roles (Bell, Butlin and Heffernan, 1995; cf. climate; heartland).

Yet the idea and practice of imperialism has a longer history, and attempts have been made to explain it in more systematic terms. It has been traced back to Antiquity and into what David Harvey (2003b) has called ‘the new imperialism’ (or ‘neo-imperialism’) currently being expedited through American military and economic overlordship (especially in the Middle East), and justified as a ‘war on terror’. The Romans left some important imperial precedents, such as the imperative to legitimize colonization by recourse to divine or secular law. However, a series of advances – initially in navigation and military technology, and then in commerce, administration and methods of knowledge production – helped European powers to create overseas empires on a scale never imagined or deemed feasible before; and recent work on imperialism emphasizes how the imperial prerogative of the West (and especially the USA: see American empire) now resides in the power to circumvent international institutions and law (see, e.g., exception, space of) and thus in some measure leave behind the moral and political legacy of Rome.

Critical approaches to imperialism emphasize its innately exploitative and dehumanizing nature (evidenced, for instance, by slavery), and – at the risk of oversimplification – have come in three main forms and phases. First, and beginning with the early-twentieth-century work of J.A. Hobson, V.I. Lenin and Joseph Schumpeter, imperialism has been analysed in economic and political terms – as central to the evolution of capitalism and the nation-state. A large historical and geographical literature seeks to account for the specificity of imperial power, and examines how different phases of capitalist accumulation (mercantile, industrial, monopoly) have been connected to different forms of imperialism (maritime and land-based, formal and
indigenous knowledge

This term represents the understandings thought to be embedded within indigenous communities (see also ABORIGINALITY), and usually posed against universalized, Western, scientific knowledge. While indigenous knowledge was regarded as a traditionalist or backward-looking barrier to effective DEVELOPMENT in the period immediately following the ‘development decade’, more recently the idea of indigenous knowledge as an alternative to increasingly discredited scientific social management and developmentalism has gained significant credibility as a way out of the ‘development impasse’. The valorization of indigenous knowledge represents a shift away from privileging the knowledge of ‘development experts’ towards the voices and experiences of the inhabitants of the global South, at whom development is usually projected, ‘listening seriously to what the rural poor have to say, learning from them and respecting their realities and priorities’ (Briggs, 2005, p. 100). Interest in indigenous knowledge is most often traced back to Chambers’ (1983) challenge to put the last first, but there are also clear affinities with the POST-COLONIAL focus on power/knowledge. POST-DEVELOPMENT writers see indigenous alternatives as offering the only real possibilities for progressive change for the majority world. For instance, Escobar (1995, p. 98) suggests that the ‘remaking of development must start by examining local constructions, to the extent that they are the life and history of the people, that is, the conditions for and of change’.

Until recently, the literature on indigenous knowledge has tended to suggest a binary between scientific and indigenous knowledge, seeing SCIENCE as a groundless set of ideas, and ignoring the HYBRID forms combining various scientific and local knowledges that
emerge in the actual practice of everyday life (Agrawal, 1995). For others, the idea of indigenous knowledge as a singular concept ignores the multiplicity and power relations inherent in any community, and is particularly problematic in terms of gender relations. This has led some to talk in terms of local knowledges (Briggs, 2005). Furthermore, a focus on knowledge can turn attention away from the material matters of development and exploitation, or the fact that while some might have knowledge, it is not always possible for them to act on it (Jewitt, 2002). Finally, some commentators have suggested caution, because the recent adoption of indigenous knowledge by development agencies such as the World Bank, while on the surface a positive move, is most often uncritical and tokenistic. In such cases, indigenous knowledge (often reduced to the singular label ‘IK’) is expected to be added to already existing knowledges and practices, rather than being allowed to offer a more fundamental challenge to the epistemologies of conventional development approaches (see Briggs and Sharp, 2004). indistinction, zone of A space in which nominally opposing categories not only become blurred (‘indistinct’) but also actively bleed into one another (cf. third space). This topological figure animates key claims in the political philosophy of Giorgio Agamben, which have attracted considerable attention in cultural, social and political geography. Agamben’s formulation of the space of exception (see exception, space of) identifies a space in which exclusion and inclusion, outside and inside, violence and law ‘enter into a zone of irreducible indistinction’ where each passes over into the other (1998, pp. 9, 32). The basis for this, he argues, is the process through which bare life is both excluded from and captured within the political order and, in its most radical form, the process through which sovereign power uses the law to suspend the legal (or juridical) order (1998, pp. 18–19). Agamben argues that the exception has now become generalized to the point at which it threatens to become the norm: ‘The “juridically empty” space of the state of exception . . . [transgresses] its spatiotemporal boundaries and now, overflowing outside them, is starting to coincide with the normal order in which everything again becomes possible’ (p. 38). Whatever one makes of such a general claim, there is compelling evidence for the multiplication of particular zones of indistinction: thus, for example, Gregory (2004b, pp. 122–36) traces the ways in which the Israeli occupation of Palestine has involved the calculated proliferation of zones of indistinction, while Gandy (2006b) suggests that zones of indistinction have become characteristic of a late-modern ‘anti-biotic urbanism’ that is producing new modes of exclusion. DG

induction A form of reasoning that moves from the specific to the general, usually deploying information/knowledge from a small number of (possible non-representative: cf. sampling) cases to develop general laws. Inductive reasoning is usually contrasted with deductive logics. (See also abduction; deduction.) RJ

Harvey (1969).

industrial district A term developed to capture the local geography, institutional density and interlinked connectivity of productive (agro-industrial, manufacturing financial and services) activities. The common reference point is the foundational work of Alfred Marshall in his Principles of economics (1919), in which he referred to industrial districts as ‘the concentration of specialized industries in particular localities’ (see locality). In its contemporary usage, the most telling property of industrial districts turn on the dynamics of close internal (intra-district) linkages based on horizontal and vertical dis-integration and the operations of particular customary norms and taken-for-granted rules and routines that collectively bind together firms and simultaneously provide the productive infrastructure of the district.

Marshall coined the term in an account of the Sheffield cutlery and specialized steel industry and the south-east Lancashire cotton textiles sector. He noted distinctive characteristics of the localities, what he called the ‘industrial atmosphere’, which collectively provided a sort of industrial hothouse with a highly competitive economic momentum. Some of the key characteristics noted by Marshall, and subsequently elaborated by others (Scott, 1988c; Amin and Thrift, 1992) included: a business structure dominated by small, locally owned firms; limited scale economies; intra-district trade among buyers and suppliers; long-term contracts and commitments between local buyers and suppliers;
a highly flexible labour market, internal to the
district; a unique local cultural identity;
specialized sources of finance, technical expert-
tise and business services available within the
district outside of firms; limited co-operation
or linkage with firms external to the district;
investment decisions made locally; labour in-
migration, with lower levels of out-migration;
and worker commitment to districts rather
than to firms.

A contemporary example of an industrial
district is 'motor sport valley' in the UK, a
cluster of firms in mid-Oxfordshire in and
through which has developed the world’s
major agglomeration of Formula 1 and Indy
car engineering (see Henry and Pinch, 1997).
This region is a community of knowledge sus-
tained by and expanding through the rapid
production, application and dissemination of
knowledge (through observation, gossip, ru-
mour and direct and indirect contact) among
and between a network of highly secretive
small and medium-size enterprises. High
rates of new firm formation and knowledge
transmission through a mobile workforce
with a small area (a 160 km long narrow cres-
cent, 60 km north and west of London) rests
on a knowledge pool and has created a 'con-
stant learning trajectory' (Henry and Pinch,
1997, p. 7). Integral to the district is a socially
and industrially created matrix of firms.

Motor sport valley is an illustration of new
industrial spaces (Scott, 1988), such as the
Third Italy and Orange Country, California,
through which the transmission of impulses
around integrated and interdependent firms
is both effective and flexible (hence the
Marshallian argument that locality exercises a
powerful influence upon productive dyna-
mism: see Storper and Scott, 1989). In these
sorts of districts, other characteristics not an-
ticipated by Marshall are specially important,
including a high incidence of exchanges of
personnel between customers and suppliers;
intense co-operation among competitor firms
to share risk, and to stabilize market share and
market instability; a collaborative system of
local innovation; a disproportionate share of
workers engaged in design and innovation;
robust trade associations providing manage-
ment training, marketing, technical or finan-
cial help; and, last but not least, a strong local
government role in regulating and promoting
core industries. This argument is compelling
in its spatiality. Geography is central, in
other words, to the 'untraded interdependen-
cies' and conventions that provide the ether in
which industrial districts flourish (Storper and
relatedly that while place constitutes social
and economic practice in the City of London
and Santa Croce in Tuscany, the way in which
this constitution takes place is itself shaped by
geographical requirements of social practice.
The localization of economic geographies is
not an autonomous or independent influence
on productive spaces, but is also shaped by
the geographical demands of increasingly global
economic geographies. One of the conditions
of existence of such geographies is the pres-
ence of a place or centre to act as a site of
representation (a centre of authority), inter-
action (a centre of sociability) and as a means
of making sense of data and information
(a centre of discourse). In short, industrial
districts are doubly geographical: both re-
quired for and constitutive of social practice.

The industrial district is not restricted to
manufacturing and financial services, but has
also been productively deployed as a way of
describing the globalization of agriculture
and the changing geography associated with
what has been called 'high-value agriculture'.
Commodity chain analysis has provided a
powerful optic through which one can explore
the emergence of key agro-industrial nodes, in
which many of the properties described in the
Third Italy or the Silicon Valley can be seen in
the agro-export region of the Sao Francisco
valley of Brazil or the wine-producing terroires
of France (see Goodman and Watts, 1997).
Here, the intersection of local specialized
knowledge (often with a deep, if modernized,
history), commercial and customary conven-
tions pertaining to inter-firm interdependence
(between growers, buyers, shipper and proces-
sors), and various forms of linkages to banking
and the local state provide for similar forms of
industrial dynamism, often draped in the cul-
tural language of attachment to the land. The
rise of the organic industry provides simply one
way in which these agricultural districts are
made and remade by shifts in, and as responses
to, industrial agriculture (Guthman, 2004).
(See also agricultural geography.)
methods, but the disciplinary norm tended to meticulous, empirically descriptive case studies of one firm, industry or industrial region or another. Iconic male-dominated industries such as sawmilling, iron and steel, and automobile assembly were the primary subject-matter; the field was thus marked by masculinism, reflecting the gender of the discipline’s practitioners and their substantive interests (a version of ‘toys for boys’), and generally uncritical methods.

In 1910, economic geographer George Chisholm drew upon the German location theorist Alfred Weber to explain ‘the seats of industry’. In the late 1950s and much of the 1960s, industrial geographers rediscovered Weber and other members of the German location school (see LOCATION THEORY), and turned to NEOCLASSICAL ECONOMIC theories of RATIONAL CHOICE and maximizing behaviour (Smith, 1981a [1971]) to explain industrial location. Propelling this disciplinary intellectual move was a combination of the QUANTITATIVE REVOLUTION in human geography, which emphasized the importance of rigour and abstraction, and the influence of REGIONAL SCIENCE, which applied neoclassical theory to the SPACE-ECONOMY, including to the optimal location of industry (Isard, 1956). However, even at the time, it was unclear exactly how many industrial geographers were convinced of the need for this more formal theorization, and most of the practitioners lacked the necessary skill set to apply it. Within a decade, neoclassical formalism was criticized by: (1) a behavioural approach (following economists such as Herbert Simon), which stressed sub-optimal outcomes (‘satisficing’) rather than maximization (Pred, 1967, 1969: see DECISION-MAKING); and (2) an institutional approach – known initially as the ‘geography of enterprise’ and later ‘corporate geography’ – which treated the firm as a complex entity, like an organism, that evolved, adapted and struggled in a larger competitive setting, was often not rational, and whose inner workings defied formalization (McNee, 1960).

The high-water mark of the field was from the late 1970s to the end of the 1980s, when disciplinary intellectual ferment matched ferment on the ground. Not only was the intellectual environment changing, so too was the very object of investigation. It was then that seemingly entrenched Western industrial regions were beset by gales of DEINDUSTRIALIZATION, industrial restructuring and corporate hollowing-out, which both destroyed and created anew. Hitherto bread-and-butter industries of Western economies, such as iron and steel, shipbuilding and textile manufacturing, were subject to severe economic trauma as firms went bankrupt, moved offshore, or turned lean and mean. Millions of traditional manufacturing jobs were lost.

Events on the ground produced new theory and new methods in industrial geography, and even began to challenge the discipline’s masculinism. Scholars began to turn to RADICAL GEOGRAPHY. In the UK, Doreen Massey’s watershed book, Spatial divisions of labour (1984), provided original theoretical explanation and trenchant empirical analysis: in the USA, Allen Scott’s (1988b) TRANSACTIONS COSTS approach to the firm was the exemplar. Both resulted in impressive empirical work: Massey’s led to the British LOCALITY project (Cooke, 1989), and Scott’s to case studies based in California, especially on the vibrant high-tech and film industries. Both bodies of work were influenced by POLITICAL ECONOMY, as well as a new methodological sensibility, CRITICAL REALISM (especially true in the UK, where critical realism became the unofficial METHODOLOGY of the discipline). Codified and circulated primarily by Andrew Sayer (1992 [1984]), critical realism suggested industrial geography proceed methodologically by ‘intensive’, on-the-ground, case studies of specific industries and their geographical sites.

Not everyone accepted ‘critical realism’, however, with critics complaining it was only another version of the old disciplinary sin of EMPIRICISM and was producing geographically parochial studies. Moreover, there was also an underlying clash between the UK version of industrial geography emphasizing capitalism’s decline and fall, and the US ( Californian) version highlighting capitalism’s vitality. However, the UK and US versions came together in the late 1980s through REGULATION THEORY, and which set the sub-disciplinary intellectual agenda for the following decade. Developed to explain why capitalism survived in spite of Marx’s best prediction of its demise, regulation theory introduced ideas of FORDIST and POST-FORDIST (see also FLEXIBLE ACCUMULATION) modes of production, and the fraught transition between them. What the distinction made clear was that while British industrial geographers had been documenting the disintegration of an older Fordist industry, US industrial geographers had been examining the formation of a brand new one, post-Fordism. They were different sides of the same Janus face of industrial capitalism (Tickell and Peck, 1992).
In unpacking the geographical character of post-Fordism during the 1990s, industrial geographers rediscovered the idea of an INDUSTRIAL DISTRICT, the propensity of firms in the same sector to cluster spatially, and to be tightly interlinked (and first recognized by the early-twentieth-century English economist Alfred Marshall). In turn, that idea was joined to ‘embeddedness’, a concept associated with the economic anthropologist Karl Polanyi, implying an inseparable relation between the economic and the sociocultural. It was precisely this inseparability, argued industrial geographers, that characterized and accounted for the success of post-Fordist industrial districts such as Silicon Valley, Hollywood, the Third Italy and Baden-Württemberg. They flourished because their firms were so closely embedded within the cultural institutions, relations and forms of life found in those places (Amin, 2000: see also CULTURAL ECONOMY).

An interest in GLOBALIZATION has recently defined the field, with investigations into both new geographical patterns of production and new forms of industrial organization that make them possible. Peter Dicken’s Global shift (2007) is the exemplary text (first published in 1988, and now in its fifth edition). The reverse side of deindustrialization has been, and continues to be ever more so, rampant industrialization in the global South: certainly the post-1979 market reforms in China, but also in India, South East Asia, Central and South America and Mexico (Dicken, 2007). Industrial geography is conceptually still coming to grips with the enormous task of representing, analysing and explaining the fundamental industrial spatial transformation that is occurring. A novel conceptual vocabulary and theoretical framework is being forged, as well as new methods, which have included COMMODITY CHAIN analysis, global networks, ACTOR-NETWORK THEORY, the analytics of TRANSNATIONAL CORPORATIONS and global ETHNOGRAPHY. All have contributed, but industrial geography remains a work in progress, as is its object of enquiry.

Industrial organization Do a small number of large firms (oligopoly) or a large number of small firms dominate an industry? Why is this and what difference does it make for industrial geography, corporate behaviour, and economic and social outcomes? These are the questions of industrial organization. Oligopoly may arise from such factors as ECONOMIES OF SCALE or collusion. The result may be spatial concentration, high profits and high wages. Competitive industries may be geographically dispersed, labour-intensive, low-margin and low-waged. Industrial organization may change due, for example, to technological shifts or the internationalization of markets. Understanding its causes and consequences illuminates the economic landscape.

Industrial revolution A transformation in the forces of production, centring on but not confined to the circuit of industrial capital (see CAPITALISM). Generally attributed to Blanqui (1837), but popularized in Britain by Arnold Toynbee, the term originally applied to a set of dramatic changes occurring in the British economy c.1760–1840, when the old economic order was ‘suddenly broken to pieces by the mighty blows of the steam engine and the power loom’ (Toynbee, 1884). Subsequent analyses identified British ‘industrial revolutions’ both earlier (in the sixteenth and seventeenth centuries) and later (towards the end of the nineteenth century), while the term has also been invoked to describe changes taking place across Western Europe and North America in the nineteenth century. This questions the unique nature of the classic industrial revolution, portraying it as simply another peak on the long-term waves of innovation and development (see Hudson, 1992: cf. KONDRAIEFF CYCLES). The gradualist perspective is reinforced by ideas of PROTOINDUSTRIALIZATION and by econometric studies. The former emphasize the continuities between modern factory-based manufacturing and earlier systems of domestic production; while the latter highlight the growth of industry earlier in the eighteenth century, and question the extent and pace of structural change in the British economy before 1840. On top of these, models of dual economies – which counterpoise a small technologically dynamic sector with a much larger traditional sector – have further qualified the revolutionary nature of change.

As with other aspects of MODERNIZATION, industrialization was temporally and spatially uneven: there were periodic crises of capital accumulation and circulation, and an increasingly heterogeneous SPACE-ECONOMY. Different products and production systems were increasingly associated with particular parts of the country, creating a new REGIONAL GEOGRAPHY that was based on industrial specialization (see Langton, 1984; Langton and Morris,
1987; Hudson, 1989). There were many different routes to industrialization: in its timing, causes and manifestation, the industrial revolution varied from place to place. Much emphasis has been placed on the availability of raw materials (particularly coal) in determining both the course and geography of industrialization (Langton, 1979; Wrigley, 1988). Linked to this is the role of transport in facilitating the exploitation of mineral resources, integrating regional economies and thus promoting industrial growth. More recent analyses have highlighted the importance of a range of sociocultural factors in which economic processes were embedded (see cultural turn). These influenced access to credit and capital, determined labour mobility and discipline, and shaped attitudes to entrepreneurship (Gregory, 1990). Linked to this, neo-institutional approaches have stressed the role of networks (of people, credit, information and towns) in effectively integrating regional economies and in shaping the industrialization process (Wilson and Popp, 2003; Stobart, 2004). Ultimately, sustained development was contingent on the establishment of a critical mass of interdependent industries, services, infrastructures and communications. The varied composition of such industrial complexes and the different production systems on which they were based, led to regional variations in the experience of industrialization. Indeed, Langton (1984) argues that as regional economies became ‘more specialized, more differentiated from each other and more internally unified’, they found expression in coherent regional cultures. Others, though, have highlighted the varied nature of production systems, work practices, and social and cultural identities within regions: most were characterized by a symbiotic relationship between factory- and domestic or workshop-based production (Berg, 1994). Recent critiques argue that these debates are too narrow in their focus, ignoring non-industrial forms of capitalism and the wider global/imperial context of industrialization. Most influential is the ‘gentlemanly capitalism’ thesis which, in broadening the geographical bounds of analysis, argues that Britain’s economy and overseas policy were driven not by the growth and needs of industrial capitalism, but by landed, mercantile and financial interests (Cain and Hopkins, 2001). Historical geographers have yet to engage fully in these debates, however: largely inspired by post-colonialism, work on empire has had little to say about economic processes and the global geographies of nineteenth-century British industrialization.

For individuals and communities, as well as for regions and nations, the industrial revolution had profound social and cultural repercussions (Berg and Hudson, 1992). Experiences of work were transformed as production was centralized and control was removed from the individual. Resistance to such change was occasionally dramatic, surfacing in a variety of protests across industrializing districts that often targeted new labour-saving machinery (Gregory, 1982, 1990; Hudson, 1989). More generally, the contours of the new political economy of industrial capitalism were sharply contested as the established relationships of a so-called moral economy were replaced by those based on the market. Of particular significance was the way in which the transformation of the labour process was central to the emergence of class consciousness. Yet the extent to which such social identities transcended local and regional allegiances remains an area of considerable debate. Moreover, the new social relations of production were structured by gender as well as class. Many of the new machines were operated by women and children, creating a new sexual division of labour in which men’s work was characterized as more skilled and (consequently) better paid (Hudson, 1992; Berg, 1994). Nonetheless, the earnings of all members of the household were vital in determining standards of living, conventionally seen as falling, then rising, as real incomes were first undermined, then augmented by industrialization. Living conditions and social relations were also shaped by the transformation of the urban milieu, which was both cause and consequence of industrial development (see Stobart, 2004). Towns grew both in number and size, with those in the industrializing districts experiencing the most rapid expansion. This caused a rapid deterioration in living conditions in many towns, as the construction of houses, and physical and social infrastructures, failed to keep pace with demographic growth. It also led to a restructuring of Britain’s urban geography and hierarchy, and with it the geopolitical relationship between centre and periphery. London remained dominant as the focus of commercial, financial and political activity, but debates and policies were, for a brief time in the mid-nineteenth century, shaped by experiences in and the concerns of Britain’s industrial towns, most notably Manchester.
industrialization The process whereby industrial activity comes to play a dominant role in the economy of a region or nation-state. Historically, industrialization has involved a more complex division of labour and the spread of mechanized production (machinofacture) in place of hand production (manufacture). These changes brought about a transformation in what Karl Polanyi called the form of economic integration, from the reciprocity of a moral economy to the market exchange of capitalism. In certain Western societies, industrialization took place spontaneously, small-scale domestic production for local consumption being replaced by larger-scale ‘factory’ production aimed at more distant markets. For Adam Smith, such industrialization formed part of the ‘natural progress’ of economic development, founded on the production of agricultural surpluses, but ultimately leading to specialist industrial regions and to international trade. Growth was organic, and the shift to mechanized production, prompted by supply being outstripped by growing demand, was dependent upon the development of appropriate technology and the accumulation of capital for investment (Berg, 1994).

As part of modernization theory, such readings of the past were instrumental in linking industrialization with development and in its portrayal as a solution to poverty in the developing world (Power, 2003). As a result, many less-developed countries made industry central to their development strategies. This planned (rather than spontaneous or ‘organic’) industrialization has generally taken one of two forms: (a) import substitution, wherein governments encourage the development of indigenous manufacturing to produce consumer goods for the domestic market, or (b) export-orientated industrialization, which aims to enhance production for overseas markets. In the 1950s and 1960s, Western governments favoured import substitution as a development strategy for the third world. Influenced by the theories of Rostow and others (see stages of growth) – which accorded a pivotal role to the availability of investment capital – they provided loans to developing countries to facilitate industrial development. The problems of such strategies were thrown into stark relief by the economic crises of the 1970s. The infusion of capital, technology and business organization from outside brought with it problems of dependency, most obviously manifest in the mounting debts of many developing countries (Schurmann, 2001). More fundamentally, Marxist scholars challenged the ‘development myth’ by emphasizing the inevitability of uneven development under capitalism.

In recent years there has been a rearticulation of modernization theory, partly through the rhetoric of globalization, which now points to the experience of developing countries experiencing rapid industrialization. Most striking are the so-called Asian miracle/tiger economies of South-East Asia, where the rate of industrial growth – much of it fuelled by export-orientated industries drawing on abundant cheap labour – has far exceeded that of Europe during the industrial revolution. China has industrialized particularly rapidly and, in doing so, has highlighted many of the mounting ecological problems associated with industrial growth. In addition to those of pollution of land, sea and air, is the more fundamental question of the sustainability of industrialization based on finite mineral resources (Phillips and Mighall, 2000). What the example of South-East Asia also shows is the emergence of service activities as an alternative source of employment and route to economic development (cf. services).

inequality, spatial The uneven distribution across space of a particular set of attributes, over which there is a moral politics of right or wrong. So, whereas spatial differentiation refers to conditions over which moral questions do not arise, spatial inequality refers instead to those characteristics over which there is a sense that their production is the result of human agency. The uneven distribution of natural resources is an example of spatial differentiation. On the other hand, variations between regions in terms of income levels or health rates would be examples of inequality. Think about the battles that have raged over the uneven distribution of access to some forms of medication, particularly between the wealthiest nations and those of the third world. Social movements of one kind or another have lobbied multinational pharmaceutical companies, in an attempt to get them to do their bit in addressing spatial inequalities in the treatment of HIV/AIDS.

Welfare geography since the 1970s has been concerned with inequality in living standards, in the broadest sense. Attention has continued to be paid to traditional concerns, such as those in differences in living...
INFORMAL SECTOR

standards, which remain of fundamental importance (Smith, D.M., 1994a). Additionally, however, work has focused on the spatially uneven distribution of sources of need satisfaction, reflecting a departure in welfare geography, away from narrow definitions of standards of living. While an emphasis on spatial inequalities can reveal the particular socio-economic trajectories of spatial units, it can run the risk of obscuring other factors at play. For example, we can think of inequality along the coordinates of CLASS, GENDER and RACE (Perrons, 2004). The categories cut across one another, so that we can now understand how all forms of identity and distinction – including those shaped by SPACE – in different contexts, produce situations in which individuals suffer the consequences of inequality. Moreover, the emphasis on spatial patterns risks losing sight of the structural basis of inequalities (Smith, 2008 [1984]).

While we might all think that spatial inequality is, by definition, bad, it cannot automatically be labelled as wrong. SOCIAL JUSTICE involves the conditions under which it might be possible to argue ethically and morally that spatial inequality is justified. Perhaps some groups or some spatial units are disadvantaged for the greater societal good. Given the rising inequalities, both within nations and between nations, what we can say perhaps is that the responsibility lies with those advocating inequality to justify their position in ways that do not fall back on trickle-down economics or NEO-LIBERALISM (Smith and Lee, 2004).

Perrons (2004); Smith and Lee (2004).

Informal sector A contested term that refers to forms of employment and exchange relations that may be some combination of the following: small-scale; unregulated, poorly regulated or over-regulated (De Soto, 1989); sometimes illegal and untaxed (the black economy); precarious; family-oriented; strongly entrepreneurial; poorly remunerated; and/or based on low-level technologies. Trying to define the informal sector more precisely is unhelpful, although one can usefully consider it in relation to its assumed opposite, the formal sector.

In the context of developing countries in the 1950s, it was widely assumed that the modern sector of an economy would in time come to replace all or most of the pre-modern economy (see MODERNIZATION). It was further assumed that the formal (‘Western’) sector of a DUAL ECONOMY was populated by unionized, mainly male workers, who enjoyed high real wages from manufacturing and a large number of benefits, including dearness allowances and paid leave. This was the (semi-)skilled labour aristocracy that Lenin had written about. The informal sector, in contrast, described an economy made up of shoe-shiners, domestic servants and other untenured workers: women, men and children who contributed little to the economy as a whole, and who had to be encouraged into the modern (manufacturing) economy from small-scale commercial or service activities.

This teleological view of the informal sector giving way to the formal sector was sharply challenged in the 1960s and 1970s. The International Labour Organization (ILO) developed the concept of an urban informal sector in 1969, when it launched its World Employment Programme. The ILO aimed to move beyond measures of the labour force in developing countries that were restricted to the employed and the unemployed. A new generation of urban–rural MIGRATION models now appeared, which suggested that migrants to the city were faced with a choice of remaining among the urban unemployed while searching for work in the formal sector, or of accepting work and lower wages in the informal economy. Non-economists, meanwhile, led by the anthropologist Keith Hart, began to challenge the terms of the debate. Instead of emphasizing the separation of the formal and informal sectors, theorists began to focus on the ways in which ‘popular entrepreneurship’ (Hart, 1973) helped to reproduce capital–labour relations in the formal sector. For example, three-wheel taxi services helped to speed up circuits of exchange in city-systems not well served by freeways or mass transit systems. Micro-enterprises subcontracted intermediate goods from formal-sector firms. What marked out the informal sector was ease of access to new entrants, including migrants, both domestic and international.

Barbara Harriss-White (2003) has suggested that the hype surrounding ‘hi-tech’ India is blind to what she calls the India of the 88 per cent, or those men, women and children who work largely unprotected in India’s agricultural, industrial and service economies. Other studies have estimated the scale of the informal sector in parts of Africa at over 50 per cent, and at over 40 per cent in Latin America and the Caribbean. The informal sector is also well entrenched in richer countries. The growth of Local Economic
Trading Systems (LETS) is evidence of this (see ALTERNATIVE ECONOMICS). So too is the growth of gardening and maid services in cities such as Miami and Los Angeles in the USA, largely staffed by labourers from Latin America.

**information economy** A term dating from the late 1960s and early 1970s, describing the growing centrality of information to the development and restructuring of advanced industrial economies. Pioneering work by sociologist Daniel Bell (1973) outlined the increasing significance of the distribution, production and consumption of information within what he called POST-INDUSTRIAL SOCIETY. Since then, human geographers – amongst many others – have made major contributions to understanding the spatial dynamics of information-intensive industries (Hepworth, 1989) and the highly uneven geographies of computer networks such as the Internet that integrate information economies (Zook, 2005: see also KNOWLEDGE ECONOMY; LEARNING REGION).

**Suggested reading**

**information theory** A mathematical approach originally developed in communication science to measure the amount of information, degree of organization or uncertainty in a system. The measure is closely related to that for entropy. The basic equation developed by Shannon (Shannon and Weaver, 1949) is as follows:

\[
H = - \sum_i p_i \log (1/p_i),
\]

where \( H \) is the information statistic and \( p_i \) is the probability (or proportion) of a variable in a given region. The individual \( p_i \)s might be employment in different regions, the proportion of agricultural land in \( N \) counties or the probabilities of \( N \) possible outcomes in a stochastic experiment. \( H = 0 \) when one of the \( p_i \) is unity – all the employment is concentrated in one region – whilst \( H \) approaches a maximum (given by \( \log N \)) when all the \( p_i \) are equal. \( H \) is perfectly related to \( \log W \), the entropy measure. Information theory was extensively applied to the measurement of social and economic INEQUALITY by Henri Theil (Theil, 1967). In geography, it has been used to measure organization in settlement patterns, information in CHOROPLETH mapping techniques and in regional classification, as well as in the applications involving ENTROPY-MAXIMIZING MODELS.

**informational city** A term coined by Manuel Castells (1989) to describe a city whose development is dominated by the restructuring dynamics of manufacturing and research and development (R&D) in ‘hi-tech’ industries (primarily information technology, defence, biotechnology and nanotechnology). Based on a detailed analysis of urban change in the USA in the late twentieth century, Castells suggested that such developments were underpinning the emergence of a global URBAN SYSTEM made up of WORLD CITIES dominated by centralized clusters of innovation in these high-technology sectors. He argued that these sectors were located in suburban complexes called technopoles, which tended to be associated with increasingly dualized social structures and the dismantling of welfare state systems (Castells and Hall, 1994).

Castells (1989).

**infrastructure** In conventional economic theory and planning, infrastructure refers to the underlying structure of services and amenities (social overhead capital, or SOC) needed to facilitate directly productive activity (or DPA). Examples include public services, transport, telecommunications, public utilities, and social and community facilities. Infrastructure tends to be immobile, labour intensive, indivisible and open of access, and to have economy-wide effects. There is considerable argument over the extent to which infrastructural investment is a sufficient or even a necessary precondition for economic development; whether it should be provided before development in the form of excess capacity or whether scarce resources should be devoted primarily to DPA; and whether it should be publicly or privately owned. Indeed, the widespread growth of the private ownership of infrastructure and its ability to generate stable returns over long periods has led to significant financial interests in infrastructural development, not just in terms of ownership and financing, but as the basis of a range of disintermediated financial instruments.

Within MARXISM, ‘infrastructure’ has a more precise and theoretically charged meaning.
It refers to the forces and relations of material production that, in Marx’s classic writings, provide the foundation (or ‘base’) for a legal, political and cultural ‘superstructure’ (see BASE AND SUPERSTRUCTURE). This formulation marked the site of a considerable debate within HISTORICAL MATERIALISM over the relationship between infrastructure and superstructure: some critics claimed that Marx saw this in reductive terms (‘economic determinism’), while most informed scholars provided more nuanced readings of the ways in which economic practices and structures are implicated in the conduct of social and political life.

**inheritance systems** In theory, inheritance is the transmission of exclusive rights in PROPERTY at death. Such transmission is part of the wider devolution of rights between holders and heirs, and usually between generations. This process of devolution can also involve transfers between the living for education, marriage and property purchase, as well as transfer of any residual at the holder’s death. In societies where production is based on the HOUSEHOLD and where property rights are vested in the domestic group, the evolution of such rights is of vital importance. In simple hoe agricultural societies, such as found over much of sub-Saharan Africa, inheritance between spouses is rare, with transfers tending to be from males to males or from females to females. In such settings, economic differentiation is limited and access to land relatively easy, with inheritance occurring within unilineal descent groups such as clans or lineage.

In plough-based agrarian systems, a diverging or bisexual form of devolution is more common, and frequently involves children inheriting from both parents and parents transferring property to both daughters and sons – and not necessarily at death. One such form of pre-mortem inheritance is dowry given to daughters at their marriage, which has been widespread in Eurasia. At marriage, some kind of conjugal fund is created and the property transmitted, although not in equal proportions, to the children. The different treatment of siblings depending on birth order takes the form of primogeniture (impartibility), multigeniture (partibility) or ultimogeniture (Borough English). Systems of impartible inheritance in which the eldest son was sole heir were common among elite groups in EUROPE, where title and position were linked to estate and income. Younger sons might seek their fortune through careers in the church or the army, to which they had access as a result of the political power embodied in the parental estate. In European peasantry (see PEASANT), the parents might hand over the farm to a son or a daughter on the occasion of his or her marriage, reserving for themselves right to bed and board, although frequently giving rise to extended or stem family households. Such arrangements might create familial tensions, since an early transfer might weaken the authority of the elderly, and a delayed transfer might create hostility towards the elderly among the young. In CAPITALIST societies, where the majority of the population has no ownership of the means of production, inheritance is of far less significance. However, the ability to transfer privilege as well as residential property is intrinsic to family life in all economic systems. Most modern societies place a progressive tax on inherited property, which could be viewed as a means of equalizing advantage. Ways of avoiding tax on personal assets at death are found in the use of trusts, life estates and charitable giving. In the USA, where charitable gifts are tax-exempt, private foundations gain enormous benefits, and in the UK major contributions to national collections of art, buildings or land result from attempts to avoid death duties (Shoup, 1966).

**inner city** That region of the metropolitan area consisting primarily of older residential areas in close proximity to the downtown core. By the late nineteenth century, inner-city neighbourhoods were mainly blue-collar districts, providing shelter for the families of working men employed in the wholesaling, manufacturing and transportation sectors that were located in the ring of industrial uses adjacent to port and railway terminals outside the CENTRAL BUSINESS DISTRICT. In the industrial city, then, the inner city was the home of the working poor, including immigrants, as famously described by the CHICAGO SCHOOL between 1910 and 1970 (Wirth, 1928; Suttles, 1968). In such cities, minimal land-use regulation introduced serious traffic congestion and severe air, land and water pollution, encouraging the withdrawal of the middle class to tram/streetcar and commuter suburbs. Separation bred a suspicion and even fear of the inner city by the middle class, a condition that survives in some nations to the present.
Consequently, a definition of the inner city cannot be limited to location and age of housing alone (see housing studies). In the past 150 years or more, the inner city has experienced a spoiled identity. The grotesque nineteenth-century imagery of Dickensian London, Engels’ poignant depictions of life in industrial Manchester, the later portrayals of Inner London by the Booths (Charles and William) and of Inner Montreal by Herbert Ames, and the photo-documentary essays of Jacob Riis in New York all consolidated a highly stigmatized image of both need and menace. In many respects, the social sciences were born into the problem of the inner city, with William Booth, the Pittsburgh Survey and the Chicago School all concerned with the mapping of various personal and social pathologies in inner-city districts. Not surprisingly, the influential verdict of the Chicago School was that the inner city was the natural habitat of individual and social disorganization. Such a judgement led easily to a view that demolition and rebuilding would effect social as well as urban renewal, and the nascent welfare state engaged in widespread clearance in older inner districts, beginning in the 1930s.

In the aftermath of deindustrialization, the inner city remains a site of social problems: Margaret Thatcher’s infamous, depreciating allusion to ‘those inner cities’ in 1987 (Robson, 1988) revealed not only an abiding social construct but also a social reality in many declining industrial centres. Indeed, in the same year as Mrs Thatcher’s declaration, William Julius Wilson (1987) published his celebrated text on concentrated and racialized urban poverty in American inner cities. His underclass thesis, drawing attention both to macro-economic employment trends as well as a culture of poverty in the inner city, established an urban research agenda. In Western Europe, an explosive literature emerged in the 1990s on multidimensional social exclusion, targeted on (but not limited to) inner-city districts, some of it importing American underclass language (Mingione, 1996; Madanipour; Cars and Allen, 1998). Addressing social exclusion and deprivation in the inner city and priming urban regeneration have become significant policy directions in many European states.

However, the fusion of place and identity that sees only social problems in the inner city is too rigid. For one thing, as the French ‘banlieue’ riots of 2005 revealed so clearly, deprivation and exclusion may be even sharper in suburban sites (see suburb). Second, the view of the inner city as a problem is an oversimplified fabrication (Ley, 2000). Just as the Chicago School displayed a patronizing suburban perspective on the inner city, so middle-class policy-makers and politicians through the urban renewal era and later have sustained the same stereotype. In her famous polemic against urban renewal, Jane Jacobs (1992 [1961]) contrasted the detached view of the urban bureaucrat with the view at ground level of urban residents in medium-density older neighbourhoods, extolling an insider’s perspective of local vitality, diversity and self-help. Her 1961 message was prophetic and in the next decade the beginnings of Gentrification indicated an equally sympathetic view of the inner city by young urban professionals. In Post-industrial cities such as London, New York, Toronto or Sydney, gentrification has led to a massive middle-class make-over of many inner-city districts (Hamnett, 2003), sometimes as an objective of regeneration policies (Cameron, 2003). Frequently, gentrification has diffused outwards from the real estate anchor of existing upper middle-class districts, whose longevity over several generations also reinforces a more accurate view of inner-city diversity rather than homogeneity. Innovation The introduction of a new phenomenon or the phenomenon itself (which may include concepts and objects, practices and systems, variously combined in products, and processes). In Human geography an early stream of work focused on the origin and spread of innovations, particularly in cultural geography, and it was the study of innovations that provided the mainspring for Torsten Hägerstrand’s development of the formal study of innovation diffusion in spatial science (itself an example of an intellectual innovation that combined new concepts such as the Mean Information Field, new objects such as the computer that enabled Hägerstrand to construct his model, and new practices such as the algorithms that powered his Monte Carlo simulations: see Hägerstrand, 1967). A more recent stream of work in Economic geography has focused on the research and development processes in which commercial innovations are embedded, on spillover effects (see clusters) and on the spatial variations in productivity that may result from differential geographies of innovation (Feldmann, 2000). Taken together,
these generate such complex outcomes over space that Morgan (2004) proposed a focus on territorial innovation systems sensitive to the multiple scales at which effects are registered, though most research continues to focus on the region (Asheim and Gertler, 2005; see also LEARNING REGIONS).

DG

**input–output** An analytical framework developed by economist Wassily Leontieff to describe and model the inter-industry linkages within the economy, and to use this information to examine economic and policy impacts. It traces how the outputs of one sector become the inputs for others: thus the machine-tools industry uses energy, steel and other inputs, and its outputs are in turn inputs to car and aircraft industries. The model requires extensive data and estimates from surveys, and the input-output table can then be manipulated to calculate multipliers and so model the impact of policy changes. These models were originally calculated at the national scale, but have been extended to regional and multi-regional models.

**institutional economics** Institutionalist thought has come to the fore in ECONOMIC GEOGRAPHY since the 1990s, following its revival in economic theory during the late 1980s around two very different strands. The first is new institutional economics, most closely associated with the work of Oliver Williamson on the theory of the firm and others such as Mancur Olson and Douglass North on the role of (public) institutions in economic regulation and evolution. In this work, the focus falls on how firms, networks and institutions arise as organizing mechanisms in the market economy, complement market transactions and generally provide stability, steer and judgment in an otherwise multi-interest and multi-directional economic space composed of competing individuals. The economy is conceptualized as a constellation of firms, markets and institutions, each working to a different logic and with specialist properties. New institutional economics does not break with mainstream economics, since it shares its core assumptions relating to individual motivation (e.g. maximization, hedonism, rational choice) and market behaviour (e.g. price as a core allocation mechanism, informational transparency).

New institutional economics has had limited impact in economic geography, having lost momentum after an initial flurry of interest sparked by extensions of Williamson’s transaction cost model to explain agglomeration. For example, Scott’s (1988c) work on high technology and other types of industrial agglomeration added an important spatial dimension to Williamson’s model by showing how proximity in conditions of specialization and inter-firm linkage served to reduce transaction costs and transactional uncertainty. More recently, there has been a slight revival, through the work of some economic geographers engaging with the work of Paul Krugman to explain inter-regional disparities on the basis of trade differentials and national or regional institutional settings.

One reason why new institutional economics has faltered in economic geography is due to the historical dominance within the sub-discipline of heterodox economic traditions critical of the methodological individualism, rationalism, formalism and a-historicity of mainstream economics. The second strand of institutional economics – old institutionalism – fits more easily into an influential lineage that includes classical political economy accounts in the 1950s and 1960s of urban and regional growth and inequality (e.g. Nicholas Kaldor, Albert O. Hirschman and François Perroux on cumulative causation); Marxist explanations during the 1970s of uneven development and unequal exchange, based on the imperatives of capitalist accumulation and the consequences of class/gender/race exploitation and struggle; and regulation theory explanations in the 1980s of long-term economic stability, structural crisis and renewal, and capitalist variety in terms of the match or mismatch between historical regimes of accumulation and regulation.

Old institutional economics, named so in recognition of influence of US pioneers such as Thorstein Veblen, Wesley Mitchell, John Commons, Clarence Ayres, John Dewey, and later Karl Polanyi and John Galbraith, envisions the economy itself as an instituted process in all its manifestations. Thus, macroeconomic rules and institutions, markets and market practices, prices and values, production conventions and exchange norms, financial rules and economic rationalities, and corporate and regional or national standards are all conceptualized as socially instituted arrangements guiding individual action. Institutions, however defined, are not seen as a particular form of organization and distant from markets, in the way that new institutional economics does, but as the very life and
INSTITUTIONALISM

substance of the economy. Institutional parameters, as Hodgson (1988) argues in his celebrated book, explain economic variety, economic impulse and organization, evolutionary change, historical specificity and rules of meaning, interpretation and action.

The term ‘institution’ covers a wide variety of meaning to progressively thicken the idea of the economy as an institution. Most obviously, this includes the formal institutions of economic and regulation such as firms, banks, corporate rules, business standards and government regulations that are societally specific, slow to change and significant channeling devices. It also includes informal institutions such as social conventions of power, deference, respect, trust and legitimacy, which are also highly localized, and which guide behaviour in different markets, organizations and territories. In turn, taken-for-granted economic canons such as profit maximization, market individualism, price signalling and actor rationality are read as value-laden in a dual sense: first, as embedded fictions that need to be worked at; and, second, as socially generated norms that are neither incontrovertible nor universal. Then, economic continuity and change are explained in terms of recursive routines and habits – personal, interpersonal, organizational and social – treated as the hidden hand of daily economic practice and consensus, as the social genes of economic evolution and path-dependency, and as a core determinant of learning and innovation capability. Old institutional economics, thus, rejects the premises of mainstream economics, but it also injects a considerable degree of texture, contingency and socio-institutional specificity in heterodox economic theory traditionally dominated by big-picture generalizations.

In economic geography, this variant of institutional economics has had some impact in development geography by soliciting critical work on the role of international organizations such as the World Bank or major NGOs; research on the social and institutional parameters of particular markets, such as micro-credit or open-air trade; and studies of local economic potential based on an analysis of formal and informal institutions, social conventions and learning processes. The conceptual thrust, however, has come from studies of urban and regional economic dynamism and creativity in the global North. Many new concepts, such as cluster dynamics, industrial atmosphere, institutional thickness, untraded interdependencies, associational ties, industrial slack and redundancy, urban buzz and creativity, trust and reciprocity, and intelligent regionalism, have been inspired by institutional economics to account for local economic success. Researchers associated with institutionalism in this field include Annelee Saxenian, Amy Glasmeier, Michael Storper, Allen Scott, Meric Gertler, Trevor Barnes, Chris Olds, Phil Cooke, Kevin Morgan, Ron Martin, Ash Amin, Nigel Thrift, Jamie Peck, Ray Hudson, Peter Maskell, Anders Malmberg, Bjorn Asheim, Gernot Grabher, Peter Sunley and Harald Bartheld.

The work of these researchers has brought new insight into the spatial dynamics of the economy in three broad areas. The first relates to the role of spatial proximity between firms such that the full benefits of specialization, agglomeration, and trust and reciprocity can be exploited. The second relates to the different ways in which social capital developed in civic associations, institutional activism and reflexivity, and public-sector leadership can contribute to local economic vitality. The third relates to the spatial foundations of the knowledge economy and economic learning in general, where the research has highlighted the significance of localized R&D, technology transfer, learning in inter-firm networks, tacit knowledge formed in interpersonal networks of common purpose and mutual obligation. This body of work has considerably expanded understanding of how space affects the institutions of economic development and change.

institutionalism A term with many meanings in the social sciences, all intended to signal the varied ways in which institutions structure social life in time and space. It is an approach that rejects actor-centred approaches that stress individual human intention and will. It also seeks to interpret structure in terms of historically and socially embedded institutions, seen to evolve slowly, often unpredictably and sometimes inefficiently. Structures are not seen as immutable, universal, or machine-like. In POLITICAL GEOGRAPHY institutionalism has influenced the study of political institutions and their effects on ELECTORAL GEOGRAPHY, and studies of geographies of belonging, citizenship and conflict. In SOCIAL GEOGRAPHY, it has had some impact on studies of social and cultural
institutions and their role in the making of space and place. But its most significant impact has undoubtedly been in economic geography, where it has forged a path between mainstream approaches and radical political economy (see INSTITUTIONAL ECONOMICS).

**instrumental variables** A statistical and econometric technique to estimate models of the regression type that have problems of endogeneity. In the standard multiple regression model of the general form:

\[ Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + e, \]

where \( Y \) is the dependent variable, \( X_1 \) and \( X_2 \) are the independent variables and \( e \) is the random error term, the assumption is that the two independent variables are genuinely exogenous. Suppose, however, that \( X_1 \) is endogenous, itself determined by \( Y \) and other exogenous variables such as \( X_3 \) and \( X_4 \). An example might be if \( Y \) represents regional employment growth in ‘hi-tech’ services and \( X_1 \) is regional income: \( Y \) is influenced by \( X_1 \), but \( X_1 \) is itself influenced by \( Y \), implying that \( X_1 \) is correlated with \( e \), a violation of the assumptions of regressions.

The technique of instrumental variables works by finding a set of ‘instruments’, variables that are themselves exogenous and are good at predicting \( X_1 \). Such a set would include \( X_3, X_4 \) (and \( X_2 \) for the version of instrumental variables known as two-stage least-squares), other \( X \) variables and perhaps spatial or temporal lagged values of \( X_3 \) and \( X_4 \). Denoting this set of instruments as \( Z \), one regresses \( X_1 \) against \( Z \), obtaining the predicted or fitted estimates of \( X_1 \), denoted as \( \hat{X}_1 \). The estimate \( \hat{X}_1 \) depends only on \( Z \), and so is uncorrelated with \( e \), and the original regression for \( Y \) is now estimated, replacing \( X_1 \) by \( \hat{X}_1 \). This procedure, which thus requires two regressions, eliminates the endogeneity bias. The limitation of instrumental variables lies in the ability to find a suitable set of instruments that is both exogenous and good at predicting \( X_1 \) – weak instruments will circumvent the endogeneity but provide poor estimates of the \( \beta \) coefficients (for a full discussion, see Bowden and Turkington, 1990).

An interesting recent geographical example, widely publicized through The Economist magazine, is a study by James Feyrer and Bruce Sacerdote of the economic prosperity of 80 former-colonial islands around the globe. They argue that the current prosperity is directly related to length of colonization, but recognize that fertile and promising islands may have attracted colonists; that is, endogeneity. They then use instrumental variables with measures of wind speed and direction as instruments: before steam-ships, such variables may well have influenced the date of colonization, but are strictly exogenous.

**instrumentalism** A philosophy of science concentrating on end results such that science becomes an instrument judged in terms of practical utility rather than the truth or falsity of theory. Gregory (1978a) identified instrumentalism as a feature of geography’s quantitative revolution, informed by a particular reading of positivism, the generation of models being welcomed for their potential to shape policy. Such work entailed a narrow conception of relevance, subsequently criticized. Concerns over instrumentalism have informed debates over geographic information systems, with calls for GIS to adopt a more critical and reflexive perspective on the conditions of its production and utilization (Pickles, 1995a).

**Suggested reading**

Gregory (1978).

**integration** The creation and maintenance of intense and diverse patterns of interaction and control between formerly more or less separate social spaces. Integration involves the bringing together of different systems of meaning and action founded in different sets of social relations. It takes place in different registers – economic, political and cultural – and so is an inherently uneven process. This is compounded because integration takes place through – not merely over – time and space: without the formation of new times and spaces, the social relations embedded in integration could not be constituted. As such, it is profoundly affected by technical change. Innovations in the movement of people and commodities, and most recently in the electronic transmission of ideas, images, information and cultural forms, have made possible new modes of interaction and new ways of being ‘present’ in other places (see time-space compression; time-space distanciation).

Places have never been closed, cellular systems; people have always been caught up in
INTELLECTUAL PROPERTY RIGHTS (IPR)

the lives of others. But the porosity of place has varied, and may be transformed forcibly (by war), peacefully (through agreement or negotiation), or through a mix of the two. Historically, colonialism and imperialism have been powerful vehicles of integration, although the processes were highly asymmetric and shot through with differentials of power and profit. Today, economic integration usually depends on market mechanisms, through the circulation of capital, labour and knowledge, through the global integration of consumer practices and consumer culture, and through political interventions in international political economy (policies on trade, investment, immigration etc.), but these processes may also have violent correlates that Harvey (2003b) connects to a continuing global regime of accumulation by dispossession.

Integration does not automatically imply the erasure of difference. Economically, it may impose or allow greater degrees of specialization and promote areal differentiation (see globalization); politically, it may raise questions about autonomy, identity and independence within national or transnational formations; culturally, it may allow the dissemination of new hybrid cultural forms (see hybridity; transculturation). All three issues have surfaced in successive enlargements of the European Union and the project of a united Europe (see Bialasiewicz, Elden and Painter, 2005). More generally and over the longer term, Braudel (1985, p. 45) emphasizes that the integrative world economy is simply 'an order among other orders', and that the struggle between integration and differentiation/distinction has always been and remains a powerful determinant of economic, political and cultural relations. RL

Intellectual Property Rights (IPR) The collective term used to refer to the protection offered by a variety of legal instruments – most notably copyright, patents and trademarks – with respect to the use of certain intangible goods including ideas and information. Typically, the holder of such rights is entitled to a temporally or spatially limited degree of exclusivity in the use of the matter in question, an exclusivity that is designed to stimulate and reward the inventiveness involved in making it useful. Like all property rights, IPRs are very much social rights, embodying how societies choose to recognize the claims of certain individuals and groups but not others to certain particularly significant and/or potentially limited things. As such, they have varied over time and between places on the one hand, and been the object of much debate on the other. A series of related developments over the past half-century or so has seen an intensification of the implications of these differences and contestations, bringing intellectual property rights to the very forefront of contemporary intellectual and political discussion.

First, a technologically enhanced ability on the part of scientists and others to translate, manipulate and circulate biological materials has multiplied the kinds of things which might potentially be covered by IPRs. Second, the advent of what has been called a ‘knowledge economy’ has seen a scramble by relevant parties of all sorts to protect as much and as many of the intangible aspects of their products and services as possible (and thereby their profits and position). Finally, moves by global bodies ranging from the United Nations to the World Trade Organization (WTO) to harmonize and regulate how intellectual property rights are defined and practiced worldwide has publicly exposed the extent and magnitude of the issues at stake, as well as the profound disagreements that need to be overcome.

At this point, it is probably fair to say that the aspect of intellectual property rights that has most exercised geographers’ interest has been the questions that they raise about the ownership of biological materials. In the 1994 Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) (which is administered by the WTO and is undergoing almost continuous renegotiation), provision was made for certain kinds of materials to be patentable. This reflected a trend since the 1970s of business interests (and especially the life science firms involved in producing medicines), to successfully argue that patents are essential for their ability to make a return on their investment in research and development required to discover, produce and get regulatory approval for new products. The idea that biological materials (if not animal, plants or processes themselves) should be privately owned – even in the temporary form offered by patents – has been hugely controversial. Some object that it is morally inappropriate that the legal-commercial logic of property should be extended to living things in any form. For others, what is inappropriate is the imposition of a Western
model of property on to situations involving peoples who might collectively make sense of the world in very different terms. What they demonstrate is how important an understanding of the legal geographies of IPRs is likely to be for the foreseeable future (see LAW). NB

intensive agriculture Intensive agriculture is broadly characterized as repeated cultivation and/or grazing of the same area of land using supplementary energy inputs to enhance the fertility of the land: it is contrasted with extensive agriculture, which involves seasonal patterns of transitory land use over large areas (Simmons, 1996). As a process, intensification refers to improving the yield on land already in production, usually by efforts to speed up, enhance or reduce the risks of biological processes in agrarian production; whereas extensification refers to bringing more land into production. Boyd, Prudham and Schurman (2001) have drawn parallels between these two ideas and MARXIAN ECONOMICS concepts regarding the subsumption of labour. Food regime theorists such as Freidmann and McMichael (1989) have used regulation theory to posit a broad shift from extensive to intensive agriculture in the postwar period, although many have contested these assumptions and have noted a much more variegated landscape of extensive and intensive production.

As a historical process, intensification has been associated with the transition from feudalism to capitalism (see ENCLOSURE), and the ensuing development of markets in land, labour, credit and farm inputs. One theory of intensification is through the penetration of commodity relations into PEASANT households. What Bernstein (1995a) has called the ‘simple reproduction squeeze’ is when inputs and reproductive needs once produced by household members need to be purchased at the same time that household members are drawn into off-farm employment, reducing the labour applied to farming and social reproduction. The prospect of declining yields and income thus forces agrarian producers to adopt more high-yielding configurations of capital, labour and technology. Blaike’s (1985) theorization as to how this squeeze can lead to soil erosion in developing countries was seminal in POLITICAL ECOSYSTEM. Since increased yield can be achieved with more rotations (fewer fallows), reduced crop loss or faster-growing varieties/animal breeds, today intensive agriculture is associated with high input use, including chemical fertilizers and pesticides, animal pharmaceuticals and growth hormones, mechanization and genetic engineering. Non-technical innovations in labour control can be considered intensification as well; for example, the use of vulnerability to ensure a timely, and compliant, labour force. Because farmers are ‘price-takers’, agriculture is plagued by systematic over-production, a problem that intensification only exacerbates. At the introduction of a new technology, early innovators enjoy surplus profits, based on improved productivity. As others jump in, price competition ensues, causing rates of profit to fall, until marginal returns are very low. Intensification has come to be associated with high land values, since land tends to be capitalized at the ‘highest and best use’ (see Guthman, 2004).

Intensive agriculture practices have become closely associated with growing public concerns about the environmental and food safety problems of industrial systems of food production. These problems range from water pollution caused by agricultural chemical runoff and the loss of biodiversity associated with monocultures, to the incubation of animal diseases such as BSE. Sometimes, the INDUSTRIALIZATION of agriculture, which can also connote corporate control, largeness or factory-like conditions, is more precisely described as intensification.

intensive research Research strategies directed towards discovering the causal chains that connect social structures, social practices and individual agents in particular time-space contexts. Sayer (1992 [1984]) argued that intensive research is typically conducted under the sign of REALISM and relies on QUALITATIVE METHODS, including ETHNOGRAPHY. As such, it is concerned with substantial relations of connection and privileges a logic of corroboration. Sayer insisted that such studies are every bit as ‘objective’ as EXTENSIVE RESEARCH and, indeed, are more powerful, since their focus on causal mechanisms means that they are likely to produce ‘abstract knowledge [that is] more generally applicable’.

internal relations Necessary relations between objects or practices that make them...
what they are. Formally, ‘a relation $AB$ may be defined as internal if and only if $A$ would not be what it essentially is unless $B$ is related to it in the way that it is’ (Bhaskar, 1998 [1979]). Internal relations are of two kinds:

(1) The relation between landlord and tenant is an internal relation, for example: in this case, each presupposes the other, so that the relation is symmetrical.

(2) The relation between the state and local authority (or ‘social’) housing is also an internal relation: the latter presupposes the former, but the converse is not true, since it is perfectly possible to think of a state that makes no provision for social housing, so that the relation is asymmetrical.

These distinctions are important for the process of abstraction that is the mainspring of the philosophy of realism, because they guard against so-called chaotic conceptions that ‘combine the unrelated and divide the indivisible’ (Sayer, 1982).

Sets of internal relations may be termed structures. Thus Harvey (1973, pp. 286–314) defined a structure as ‘a system of internal relations which is in the process of being structured through the operation of its own transformation rules’. In his subsequent writings, Harvey provided a more developed account of the structures of capitalism as a mode of production and, in particular, of the dialectic within which ‘each moment is constituted as an internal relation of the others within the flow of social and material life’ (Harvey, 1996, p. 81; see also Jessop, 2006). Harvey was following Marx, and his project was directed towards what he termed historico-geographical materialism (see Marxism; materialism). In his exploration of the philosophy of internal relations, however, Olsson (1980) elected to follow a radically different direction. For Olsson, echoing Hegel in a transposed key, thought, language and action are internally related to such a degree that ‘the world and our ideas are so entangled in each other that they cannot be separated’. Hence, so he claimed, ‘social relations between people [are] like logical relations between propositions’ and vice versa: they are all internal relations. This prompted Olsson to make a linguistic turn and embark upon a series of linguistic experiments that took him into the realms of surrealism and beyond, but always circling around the internal relations that skewer thought-and-action through the logics of ‘cartographic reason’ (Olsson, 2007).

International Monetary Fund (IMF) One of the two international financial institutions created at the meeting of national leaders held in Bretton Woods, New Hampshire, shortly before the end of the Second World War – the other being the International Bank for Reconstruction and Development, better known as the World Bank. A third proposed Bretton Woods institution, the International Trade Organization (ITO), was stillborn because of opposition from the US Congress, and a body with the powers to be accorded the ITO did not come into existence until the founding of the World Trade Organization (WTO) in 1996.

The IMF was created with the task of promoting international trade through facilitating monetary co-operation, and it was allocated funds for the specific purpose of helping countries get past short-term balance-of-payments crises. This made its tasks complementary to the longer-term development funding undertaken by the World Bank. Both institutions had a somewhat Keynesian mandate. The Articles of Agreement of the IMF included among the purposes of the organization to ‘facilitate the expansion and balanced growth of international trade, and to contribute thereby to the promotion and maintenance of high levels of employment and real income’. This was to be accomplished by promoting exchange rate stability among national currencies and avoiding ‘competitive exchange depreciation’ (Holborn, 1948, p. 172).

With the breakdown of the fixed exchange rate regime in the early 1970s, however, the IMF began to take on new and distinctly anti-Keynesian roles that mark the beginnings of neo-liberalism. The IMF is today more favourably inclined towards floating exchange rate regimes, even when this results in competitive devaluations, and its favoured policies of structural adjustment have frequently sacrificed goals of high employment and wages in favour of ensuring international financial investors against the consequences of inflationary government policies such as domestic price supports (Payer, 1974; Kolko, 1988, pp. 265–9).

In its role as the dispenser of short-term funds to countries undergoing balance-of-payments crises, the IMF has increasingly demanded as its price for loans conformity by recipient governments to neo-liberal policies
This has generated criticisms from a range of popular organizations, governments and economists, making the IMF somewhat of a lightning rod for criticisms of neo-liberalism, especially in the wake of the 1997 Asian economic crisis, when many critics perceived IMF policies to have been inappropriate and to have exacerbated the crisis (see ANTI-GLOBALIZATION). In addition, because voting rights at the IMF are allocated on the basis of contributions, and because the US government is the leading contributor, the IMF has been seen by many critics as a USA-dominated institution, pushing an agenda favoured by the US Treasury Department (Stiglitz, 2002).

International relations
The term has two meanings: (1) the relations between states; and (2) the study of international politics (where it is often abbreviated as IR).

(1) International relations are conventionally understood as the political issues (especially foreign, defence and security policy) that take place between states and beyond the borders of states. These ‘high politics’ are sometimes said to be in contrast to the ‘low politics’ of domestic issues. In this conception, states are understood to be bounded and sovereign, unitary and rational, and the primary actors on the international stage. World politics is thus understood as the sum of diplomatic, economic, military and political interactions between states as they prioritize their national interests and seek security by maximizing power. This view is said to be historically valid, traceable to thinkers such as Thucydides and Machiavelli, and formalized in agreements such as the 1648 Treaty of Westphalia.

This conception of world politics as international relations – which shares much with classical approaches to geopolitics – can be questioned empirically. International trade, the global circulation of capital and the movement of labour involve ‘non-state’ actors (e.g. corporations, markets and migrants) and traverse both ‘domestic’ and ‘foreign’ spaces, demonstrating that the varied scales of local, national and global are intertwined. Environmental issues, the transmission of disease, mobile cultural forms and fundamentalist religions are social forces that call sovereign spaces into question. They are developments that can require transnational governance that involves co-operation rather than conflict, collective interests rather than national priorities, and international organizations rather than military alliances.

International Relations – especially when capitalized as IR – represents the academic study of relations between states and international politics. Although previously approached via the study of law, history and politics, as a formal discipline IR was established in the aftermath of the First World War, with positions at the University of Wales, Aberystwyth and the London School of Economics. As a predominantly Anglo-American enterprise ever since, IR has been subject to a series of paradigmatic debates that have pitched realists against idealists, scientists against historians, and globalists against statists. Only in the past 20 years or so, however, have the metatheoretical assumptions – the questions of epistemology and ontology – of all these contending positions been subject to debate. Drawing on developments in critical social theory associated with theories of discourse – which have also been behind developments in critical geopolitics – this intellectual ferment has seen questions of borders, identities and the construction of international order receive much greater attention. Approaches derived from constructivism (see SOCIAL CONSTRUCTION), FEMINISM, MARXISM, POLITICAL ECOLOGY and POST-STRUCTURALISM have taken on, but not displaced, the realist and neo-realist mainstream in the study of international politics.

Internet
A vast network of interconnected computers used to make the information, services, data and programs stored on one computer accessible to remote users, permitting them to purchase goods, download music, query databases, communicate messages and so forth.

Whilst partly developed from US defence research during the Cold War, the Internet’s
INTEROPERABILITY

The ability for something to work or interface between separate operations or systems without error or changed meaning. For example, digital downloads from online music stores to portable storage devices are facilitated by interoperability standards such as MP3 audio compression. The converse to interoperability is proprietary data formats locking the user into particular software. This was a problem with GIS, addressed by the Open Geospatial (formerly, Open GIS) Consortium leading the development of standards for geospatial and location-based services (www.opengeospatial.org) – including the Geography Markup Language (GML), a schema for the modelling, transport and storage of geographical information.

intervening opportunities A concept developed by the American sociologist S.A. Stouffer (1940) to explain migration patterns and subsequently applied in studies

birth date is usually taken to be 1985, when the US National Science Foundation created NSFNet, allowing universities access to five supercomputer centres. Other networks existed at that time (e.g. the UK’s Joint Academic Network and CompuServe’s networking capabilities for corporate clients), but NSFNet was TCP/IP enabled: it used the protocols underpinning the Internet today, directing ‘packets’ of data to computers by assigning unique addresses to host networks and machines (e.g. IP address 68.142.226.55 is yahoo.com).

The Internet emerged as a public utility due to the popularity of the World Wide Web (WWW) – a series of interconnected documents (web pages). This development is credited to Tim Berners-Lee, who fused the concepts of hypertext (e.g. the ability to hyperlink pages) with the architecture of the Internet and developed the first web browser, in 1991. Amazon.com began in 1995, the same year that the Java programming language was integrated with a web browser. Google started life as a research project in 1996 – the year in which Microsoft’s Internet Explorer was incorporated into Windows. Wikipedia, the free online encyclopaedia (and invaluable resource for this Dictionary entry), was launched in 2001.

Clearly, the Internet and WWW have grown rapidly in both use and scope. Whilst future trajectories and their long-term socio-economic effects are difficult to judge, recent history is suggestive. The ‘dot.com bubble’ may have peaked in 2000, but e-commerce (including online banking and music downloads) is still growing (e.g. downloads contributed 6 per cent of total worldwide record sales in the first half of 2005 – a 350 per cent increase in value from 2004: www.ifpi.org). If cyberspace develops as a dominant transaction space, then undoubtedly it will impact upon service- and retail-sector employment, and perhaps also on the landscapes of commerce. (Will the iconic ‘high street’ of shops and services be threatened by e-commerce or benefit as specialist shops are able to extend their global reach?) The Internet also contributes to alternative workplaces and practices, including home-working and ‘hot-desking’, and the collaboration of geographically separated persons in virtual meeting rooms and e-seminars (technologies that are being used to facilitate e-learning, taking traditionally place-bound universities into global education markets and ‘knowledge economies’).

It is likely that the WWW will continue to be the primary point of access to more and more information in online repositories, archives and data warehouses. Who should control or own this information? Google’s Book Search facility allows the full text of books to be searched but has involved digitizing the book collections of some libraries, raising copyright concerns amongst some publishers and authors. Other parties may want to restrict access to certain information for various reasons, including anti-terrorist protection or to close down undesirable websites. When Google.cn was launched in 2006, Chinese regulators required that ‘sensitive information’ be removed from its search results. This occasionally happens in France, Germany and the USA too (source: Google official blog).

Finally, whilst the Internet–WWW network can confidently be predicted to expand, it is unlikely to be perfectly ubiquitous. There are digital divides globally in terms of communication infrastructures, as there are nationally (e.g. broadband access is uneven across the UK, generally to the detriment of rural areas). Other geographies of cyberspace reflect on who owns the various components of the Internet–WWW (including IP addresses, content and service provision), raising social and geopolitical questions (see geopolitics). of commodity flow, passenger trips, traffic movements and so on. The volume of movement between an origin and a destination is proportional to the number of opportunities at that destination, and inversely proportional to the number of opportunities between the origin and the destination. Stouffer argued that distance of itself has no effect on interaction patterns and that any observed decline in the number of movements with distance (see distance decay) is due to the increase in the number of intervening opportunities with distance. A variant of this approach was developed in Fotheringham’s (1983) ‘theory of competing destinations’.

**Interviews and interviewing** Widely used methods for learning about the experiences, attitudes and demographic characteristics of individuals, households or groups. Interviews can be structured or unstructured, and they can be administered face-to-face, over the telephone or via email. An interview using a survey questionnaire follows a set order of pre-established questions. Survey data underpins large scale quantitative social science, and can be effective for establishing attitudinal, demographic and socio-economic patterns across large samples representative of vast populations (see quantitative methods; sampling; survey analysis). A census is a national survey of the entire population. Unstructured interviews are more conversational than a questionnaire, and allow interviewees to express the details and meanings of their experiences in their own terms and at their own pace. Unstructured interviews can be conducted with individuals, households or as focus groups, and are an appropriate qualitative method for understanding complex and contradictory social processes and experiences, and when respondents need the opportunity to explain and qualify their accounts. But even the least structured ethnographic interview is very different from an ordinary conversation. It is important for an interviewer to recognize this, so as not to be caught within implicit rules of social conversation (Anderson and Jack, 1991). In contrast to ordinary conversations, the norm in ethnographic interviews is to repeat questions, ask for clarification of terms, and introduce a series of ethnographic explanations and styles of questions (Spradley, 1979; see ethnography). Because they are unstructured, in-depth interviews are time-consuming (they typically last for between one and two hours), and the sample is usually much smaller (and likely less representative of the population) than is the case for questionnaire surveys.

There has been considerable discussion of the influence of the interviewer on what is told and heard, and of the power dynamics between interviewers and interviewees. Although it is advisable for interviewers to dress and comport themselves so as to ‘fit in’, it is widely assumed to be impossible and undesirable for them to neutralize their presence. The researcher is integral to the interview process, and his or her gender, age, sexuality, class and race (and many other characteristics) will affect access and what they are told. In survey research, this is known as the ‘interviewer effect’. There are two issues here. First, what we are told is situational, depending on the perceived social characteristics of the interviewer, the location of the interview, and many other contextual factors. Second, because most interviews are structured by ‘a division of labour in which one talks and one listens’, relations of oppression and domination may be unwittingly reproduced within them (Bondi, 2003, p. 70; but see England (2002) and McDowell (1998) for a different set of dynamics when interviewing elites). Both concerns have led to recommendations that interviewers reflect upon their positionality in order to assess how they may be affecting (and affected by) the interview situation (see situated knowledge). Rose (1997b) cautions, however, that there are limits to such reflexivity, because we are not and cannot be fully conscious or transparent to ourselves; and Bondi (2003) notes that much communication within an interview is non-verbal and non-cognitive (see also non-representational theory). Power relations, and points of commonality and difference between interviewers and interviewees are also mobile and complex (McDowell, 1998; Kobayashi, 2001; Crang, 2002; England, 2002). Concerns about power relations have led to experiments training and working with community-based interviewers (Gibson-Graham, 1994; Pratt, 2004), and to calls for more activist research (Kobayashi, 2001; see also activism, action research).

Key objectives for any unstructured interview are to create an intersubjective space in which the interviewee can express him or herself fully, and to strive to understand what is communicated as fully as possible, whilst causing no harm to the interviewee. Bondi (2003) makes a distinction between empathy and identification: the former (the recommended stance) involves the capacity to understand the interviewee’s feelings
INTIFADA
without becoming absorbed within and over-
whelmed by them. If overwhelmed, the inter-
viewer can move too quickly through difficult
topics, or rush to comfort the interviewees
without allowing them the opportunity to
fully express their thoughts and feelings. Un-
structured interviewing involves a process of
‘learning to listen’ rather than searching to
confirm pre-existing ideas or theories. And-
erson writes of her disappointment with the
transcripts from her life history interviews
with rural women, because the transcripts
lacked detail and offered little insight into
these women’s emotional lives. Anderson
closely and very usefully analyses the many
moments in her interviews where she fore-
closed opportunities for women to describe
their lives, and thus subtlety communicated a
double message: ‘Tell me about your experi-
ence, but don’t tell me too much’ (Jack and
Anderson, 1991, p. 15). She recommends that
all researchers review their transcribed inter-
views ‘to listen critically to [their] interviews,
to [their] responses as well as [their] answers.
We need to hear what [the interviewee] im-
plied, suggested, and started to say but
didn’t. We need to interpret their pauses and,
when it happens, their unwillingness or inabil-
ity to respond’ (Jack and Anderson, 1991,
p. 17). As this quote suggests, qualitative
interviews typically require textual rather
than the statistical analyses typical for ques-
tionnaire surveys. The desire to extract the
most meaning from transcripts has led some
researchers to use transcription systems
developed for conversational analysis, in
which attempts are made to signal pauses
and capture some of the emotional content
of the interview within the transcription
(England, 2002).
Domosh (2003) has criticized geographers
for tending to analyse interview transcripts as
if they are authentic expressions of experience.
The need to examine interview data as
DISCOURSE and PERFORMANCE rather than
raw experience is nicely demonstrated in
Visweswaran’s (1994) description of her dis-
cover that several of her interviewees had deceived her. Her analysis shows interviews
to be performances in which the interviewees display limited and sometimes falsified aspects
of their selves and experiences. Rather than worrying about the fact of deception, Viswe-
waran tries to understand why she was told
particular things for specific reasons. These
reasons include the fact that interviewees
were unable to express some ideas or criti-
cisms within dominant discourse. It is only
through repeated interviews, supplemented
by ethnographic and archival research, that
she is able to glean this. Nightingale (2003)
approaches the incompleteness of in-depth
interviews from another angle, stressing the
advantage of mixed methods. Given the partial
nature of all knowledge, she recommends
that interview material be combined with
other types of data, and that it be treated as
no more authentic or less mediated than quan-
tified forms of data, in the case of her research,
remote sensing maps. Because survey methods
are more appropriate for establishing patterns
over a large population, they can be used
effectively in combination with qualitative
interviews.
There are many excellent methodology text-
books that introduce the basics of interviewing
methodology, including Limb and Dwyer

intifada A popular uprising against military
occupation (see OCCUPATION, MILITARY), de-
uced from the Arabic for a ‘shaking off’. The
term originated in two phases of Palestinian
resistance to Israeli occupation. Israel occupied
Gaza and the West Bank in 1967 and, despite
United Nations Security Council resolutions
and international law, encouraged its civilians
to establish colonies (‘settlements’) there (see
VERTICALITY, POLITICS OF). The First Intifada
was a spontaneous uprising that began in
December 1987. It involved a disengagement
from systems of Israeli administration and
developed into a vigorous assertion of the
Palestinian right to national self-determination.
After a protracted struggle, the uprising came
to an end in 1993 with the signing of the Oslo
accords, the promise of a phased Israeli with-
drawal and the establishment of the Palestinian
National Authority. The process of Israeli
colonization continued unchecked, however,
and in September 2000 a Second Intifada,
the al-Aqsa Intifada, broke out (Carey, 2001;
Gregory, 2004b). It was rooted in the failure of
the ‘peace process’ and the accelerated dispos-
session of Palestinians, but it spluttered to an
end during 2005. The Second Intifada was
more desperate and more violent than the
first: B’Tselem, the Israeli Center for Human
Rights, estimates that 422 Israelis and 1,551
Palestinians were killed between 1987 and
2000, whereas 468 Israelis and 3,418
Palestinians had been killed from 2000 through
to April 2006. The term ‘intifada’ was also invoked by some Iraqi political movements opposed to the US occupation since 2003 and by some Lebanese activists in their struggle against Syrian domination in 2005.

Invasion and succession A concept adapted from Ecology by sociologists of the Chicago School to describe processes of Neighbourhood change within cities. Within ecology, the concept is derived from ideas regarding the ‘survival of the fittest’ in the competition for living space (cf. Darwinism).

According to the Chicago School model of urban residential patterns (cf. Zonal Model), the main stimulus to urban expansion is Immigration of relatively low-income groups. These are largely constrained to low-cost, high-density, relatively poor-quality housing, much of which is concentrated in the Inner City; in addition, many move to that area because of the presence there of family and friends who assist their initial Assimilation to a new milieu (cf. Chain Migration). The pressure that this puts on inner-city housing stock stimulates existing residents to seek housing further from the centre, initiating a ripple effect through all of the city’s zones with residents on the urban edge responding by moving into new housing. Growth at the centre thus leads to expansion on the Urban Fringe through a process of Filtering, whereby housing moves down the socio-economic scale as one group replaces another in a neighbourhood, whilst households move up the housing scale in terms of housing age and quality.

Given the context in which the model was developed – 1920s Chicago – many of the immigrants who initiated the invasion-and-succession sequence were members of ethnic minorities (see Ethnicity). Their movement into areas might be challenged, causing housing stress (as densities then build up in the areas that they already occupy), until eventually pressure on an adjacent area leads to its residents yielding (cf. Blockbusting).

Investment Most commonly discussed by geographers in the context of Foreign Direct Investment (FDI), which Dicken defines as ‘direct investment which occurs across national boundaries, that is, when a firm from one country buys a controlling investment in a firm in another country or where a firm sets up a branch or subsidiary in another country’ (2003, p. 51). FDI involves either an ‘organic/greenfield’ strategy, in which investment is used to establish operations in an overseas country from scratch, or a ‘merger’ strategy, where investment is used to buy an existing operator.

When a firm or individual makes an investment, the aim is usually to reap financial benefit, either by selling the commodity or resource purchased at a later date at a profit (as investment banks do through stock and commodities markets) or by extracting value-added in some other way. FDI usually follows the latter strategy, aiming to use an overseas investment to enhance long-term profitability by extracting value from presence in another country. As Dunning and Norman’s (1987) ‘theory of international enterprise’ suggests, FDI can allow: (1) the leverage of existing assets overseas, usually resulting in increased sales and profits; and/or (2) access to new assets, again resulting in either increased sales (through innovation, for example, when the asset is skilled labour) or improved profitability (e.g. when costs are reduced because access is gained to cheap labour).

The geography of investment can be studied at two scales. At the macro scale it is possible to study the worldwide aggregate trends in FDI. Shatz and Venables (2000) show that: (1) the developed countries provide the dominant origin of FDI (~90 per cent), although traditional sources such as the USA and the UK are declining in their relative share because of the growing importance of Eastern European and South East Asian nations; (2) the developed nations are also the dominant receivers of FDI (~70 per cent). This does not, however, mean that developing countries are not important sources and sinks of FDI. Indeed, there are a small number of countries that are significant destinations for FDI because of the way firms seek to exploit the New International Division of Labour. Predominantly, though, FDI is used to access developed markets, in particular as a strategy to overcome trade restrictions and access consumer markets.

At the micro scale the patchiness of the geography of investment can be explored and theorized. Firms usually choose a place for investment that will bring particular market or asset benefits. For example, those seeking
access to knowledge-rich workers will seek to invest in clusters, such as Silicon Valley (Saxenian, 1994), rather than rustbelt districts of a country. Those seeking access to markets will seek out agglomerations where demand is high, such as advertising and law producer service firms that congregate in the world cities of London and New York (Sassen, 2006). This means, however, that those regions that fail to attract investment can become backwaters of the global economy, as has been experienced to a certain extent in the North East of England since the closure of the coal mines in the 1970s and 1980s (Hudson, 2005) and the American Rust Belts, around Detroit in particular (Glasmeier, 2005).

Shatz and Venables (2000).

Irredentism The claim by the government, or by political groups, of one country that a minority living in a neighbouring country belongs instead to it because of historical and cultural connections. Though at times the minority may live in peace within the neighbouring country, in other contexts irredentist movements may mount a campaign to ‘unite’ the minority, leading to border disputes, active guerilla-like conflict (as in Northern Ireland), and even war. The term originated from a disputed part of Austria in 1871, which Italian nationalists called Italia irredenta, or unredeemed Italy. The 1990s war in the former Yugoslavia was driven by a combination of irredentist claims. CF

Isolines Lines on a map describing the intersection of a real or hypothetical surface with one or more horizontal planes. On a topographic map, typically compiled from aerial photographs by stereocompilation (Lyon, Falkner and Bergen, 1995), each isoline, or contour, represents a constant elevation, and because the vertical interval is constant, their relative spacing is a readily visualized indicator of slope. On a statistical map, isolines may be threaded manually through a network of data points or plotted automatically by an interpolation algorithm, which provides comparative consistency and gives the map author some control over the appearance and reliability of the map (Schneider, 2001). Spot heights are occasionally added to emphasize local minima and maxima. MM

just war  A war whose cause and conduct can be ethically justified (see ETHICS). The desire to specify the conditions under which it is morally acceptable to resort to military VIOLENCE has a long and complicated history, in which RELIGION, GEOPOLITICS and LAW have all played central roles.

Christianity has embraced both a presumption against war and a belief that war may be justified to spread or defend the faith (the Crusades) or to combat evil. In Islam, the concept of jihad involves a struggle against evil, but the 'greater jihad' is a personal, spiritual struggle, while the 'lesser jihad' is reserved for armed struggles to spread or defend the faith (Devji, 2005). Much of the rhetoric surrounding the 'war on terror' (see TERRORISM) has traded on these twin versions of a supposedly 'holy war', Christian and Muslim, but within both theological traditions geopolitical and juridical issues have also loomed large.

Both theological traditions have invoked a GEOGRAPHICAL IMAGINARY in which the locations of the sacralized 'heartland' or HOME- LAND and that of the enemy Other are identified. Modern geopolitics has often appropriated the language of Just War traditions too, but typically in a secularized form in order to legitimize conventional wars and, more recently, military interventions in the name of what Chomsky (1999) calls a 'new military humanism' (cf. Douzinas, 2003; see also HUMANISM). But Megoran (2008) objects that, while CRITICAL GEOPOLITICS has no hesitation in advancing all sorts of normative claims and moral judgements, it has conspicuously failed to interrogate its own ethical presuppositions in any systematic and detailed fashion. In opposing some wars and endorsing others, practitioners of critical geopolitics have implicitly adopted the categories of just war reasoning, he argues, but ironically failed to subject them to critical scrutiny. This has a number of consequences, Megoran concludes, the most important of which is a silence over the production of spaces of non-violence and 'a vision of peace and justice that explicitly eschews the resort to force' (p. 494). This is true of HUMAN GEOGRAPHY more generally, however, which has long been more invested in WAR than in peace (cf. Wisner, 1986).

Modern juridical doctrines of just war distinguish (1) law governing when a war may be fought (jus ad bellum) from (2) law governing how a war is to be conducted (jus in bello). In general, the first requires a just cause (for example, self-defence, not aggression), a declaration by a legitimate authority, a right intention (so that the motivation must be moral rather than, for example, economic: cf. RESOURCE WARS) and a reasonable prospect of success. The second requires, among other things, discrimination between military targets and civilians, the proportional use of force, and the humane treatment of prisoners of war and civilians (cf. Gregory, 2006). These two sets of requirements raise considerable philosophical and legal issues, and several commentators insist that they need to be suspended in situations of 'supreme emergency' (Walzer, 2000) (cf. EXCEPTION, SPACE OF). But they have been put under further strain by new forms of war and their geographies, including the 'war on terror', which raise complex questions about SOVEREIGN POWER and TERRITORY, and which often refuse any clear distinction between military and non-military spaces. The rhetorical power of a 'just war' depends on more than legal arguments, however: it also depends on the mobilization of IMAGINATIVE GEOGRAPHIES to legitimize the identification and characterization of the enemy – which is, of course, where theological and geopolitical claims so often make their most forceful appearance (Falah, Flint and Mamadouh, 2006).

Megoran (2008).

just-in-time production  A system of manufacturing in which inputs are supplied and outputs are delivered very soon after demand for a finished good has been registered. Perfected by Japanese automobile producers, and since emulated by North American and European assemblers, this set of practices has also diffused to other industrial sectors such as computer manufacturing. As one
objective is to reduce the quantity of producers’ capital tied up in inventories of parts and finished products, producers no longer keep large buffer stocks on hand. This has the consequent effect of forcing lower defect rates in parts supplied, and hence improves overall quality. Because suppliers are able to meet buyers’ varying requirements (in both number and type) at short notice, the system allows manufacturers to respond more flexibly to changing market demands (see, more generally, FLEXIBLE ACCUMULATION and POST-FORDISM). Adoption of such practices may exert an AGGLOMERATION effect, bringing buyers and suppliers closer together to facilitate rapid delivery at short notice, but in any case transforms the dynamics of the COMMODITY CHAIN.
Kantianism A philosophy developed by Immanuel Kant (1724–1804) (see Kuehn, 2001). Kant’s conception of the nature of geography and its location within the system of knowledge as a whole provided the basis for a series of major disagreements in the twentieth-century discipline (see May, 1970). Kant considered that knowledge could be classified in two ways: either logically or physically (cf. classification): ‘The logical classification collects all individual items in separate classes according to similarities of morphological features; it could be called something like an “archive” and will, if pursued, lead to a “natural system”’ (Büttner and Hoheisel, 1980). In a ‘natural system’, Kant noted, ‘I place each thing in its class, even though they are to be found in different, widely separated places’ (cited in Hartshorne, 1939). He assumed this to be the method of all the sciences except history and geography, which depended, in contrast, on physical classification. The physical classification collects individual items that ‘belong to the same time or the same space’. In this connection, Kant asserted:

History differs from geography only in the consideration of time and [space]. The former is a report of phenomena that follow one another (Nacheinander) and has reference to time. The latter is a report of phenomena beside each other (Nebeneinander) in space. History is a narrative, geography a description. Geography and history fill up the entire circumference of our perceptions: geography that of space, history that of time. (Kant, cited in Hartshorne, 1939)

Although Kant’s views on geography were broadly similar to those of architects of the modern discipline like von Humboldt and Hettner, they appear to have had ‘no direct influence’ other than ‘as a form of confirmation’ (Hartshorne, 1958; but cf. Büttner and Hoheisel, 1980). Indeed, they were not explicitly endorsed in any programmatic statement of the scope of geography in English until Hartshorne’s account of The nature of geography (1939), which accepted that geography’s basic task was essentially Kantian: Geography and history are alike in that they are integrating sciences concerned with studying the world. There is, therefore, a universal and mutual relation between them, even though their bases of integration are in a sense opposite – geography in terms of earth spaces, history in terms of periods of time.

Others were more sceptical. Blaut (1961) concluded that, for Kant,

Knowledge about the spatial location of objects is quite distinct from knowledge about their true nature and the natural laws governing them. The latter sorts of knowledge are eternal and universal, are truly scientific [whereas] spatial and temporal co-ordinates are separate and rather secondary attributes of objects, and spatial and temporal arrangement of objects is not a matter for science.

Like Schaefer (1953), therefore, Blaut saw Kant as the originator of an exceptionalism that was inimical to the explanations and generalizations (rather than mere ‘descriptions’) required for geography to be reconstituted as a spatial science. That this was not a necessary consequence was later demonstrated by Torsten Hägerstrand, who revitalized Kant’s distinction in order to demonstrate the possibility of a recognizably scientific approach to physical orderings. Although time-geography was predicated on a rejection of divisions between ‘history’ and ‘geography’, ‘time’ and ‘space’, the contrast that Hägerstrand drew between a conventional compositional approach and his own contextual approach paralleled that between ‘logical’ and ‘physical’ classifications (see contextuality).

Most of the foregoing formulations depended on Kant’s lectures on physical geography delivered from 1755 to 1796 and recovered from various notes, but other writers drew attention to Kant’s Critique of pure reason (1781) and its emphasis on ‘the structuring activity of the thinking subject’ to develop an alternative to spatial science:

Space is not something objective and real, nor is it a substance or an accident, or a relation, but it is subjective and ideal and
proceeds from the nature of the mind by an unchanging law, as a schema for co-ordinating with each other absolutely all things externally sensed. (Kant, cited in Richards, 1974; emphasis added)

This stress upon ‘the epistemic structuring of the world by the human actor was the essence of the Kantian heritage’, so it was claimed, and ‘constitutes the common theme which has, in practice, been distilled from the variety of humanistic philosophies to which geographers of a subjectivist orientation have turned in their endeavour to transcend the dichotomy inherent in subject–object relations’ (Livingstone and Harrison, 1981a: see BEHAVIOURAL GEOGRAPHY; HUMANISTIC GEOGRAPHY).

Many of these endeavours might more properly be described as neo-Kantian. Neo-Kantianism emerged in Germany in the closing decades of the nineteenth century. Whereas Kant had held the a priori to be ‘externally fixed and eternally immutable’ – the ‘unchanging law’ in Richard’s quotation above – the neo-Kantians rejected the vision of a unitary scientific method that this allowed. They substituted a key distinction between:

- the cultural and historical sciences (the Geisteswissenschaften), which dealt with an intelligible world of ‘non-sensuous objects of experience’, which required interpretation and understanding (verstehen), and which were thus concerned with the idiographic – this was the focus of the ‘Baden School’, which included Windelband and Rickert – and
- the natural sciences (the Naturwissenschaften), which dealt with the ‘sensible world of science’, which required explanation (erklären), and which were thus concerned with the nomothetic – this was the focus of the ‘Marburg school’, which included Cassirer.

Within HUMAN GEOGRAPHY, neo-Kantianism has been seen at work in the POSSIBILISM of the early-twentieth-century French school of geography (Berdoulay, 1976), in the programme of the CHICAGO SCHOOL of urban sociology (Park completed a doctoral dissertation under Windelband: Entrikin, 1980), and in HUMANISTIC GEOGRAPHY more generally (Jackson and Smith, 1984). In a still more fundamental sense, Entrikin (1984) proposed that Hartshorne’s view of the nature of geography (above) incorporated a number of patently neo-Kantian arguments, and that Cassirer’s writings might provide a means of reinvigorating geography’s various perspectives upon space (see also Entrikin, 1977).

Until recently, most geographers limited their interest in Kant to his lectures on physical geography and his first critique, largely – one suspects – because of their interest in (or objections to) the scientificity of geographies underwritten by POSITIVISM. But several writers have since reflected on Kant’s second and third critiques, Critique of practical reason (1788) and Critique of judgement (1790–9). In the closing decades of the twentieth century there was a widespread (if often tacit) acceptance of an essentially Kantian distinction between three forms of knowledge or ‘reason’. Following Habermas, for example, several writers associated the ENLIGHTENMENT project in particular and MODERNITY in general with the formation of three autonomous spheres (see table).

| science | truth and knowledge |
| morality | cognitive–instrumental rationality |
| art | norms and justice |
| | moral–practical rationality |
| | authenticity and beauty |
| | aesthetic–expressive rationality |

The task of Habermas’ version of CRITICAL THEORY was, in part, to re-balance these three spheres: to guard against the inflation of ‘SCIENCE’ (and the detachment of its expert culture from public scrutiny) which he believed was characteristic of CAPITALISM in the early and middle twentieth century; and against the inflation of the aesthetic that he saw within late-twentieth-century POSTMODERNISM (Ingram, 1987). Certainly, Kantian aesthetics played an important part in discussions of postmodern sensibilities in human geography, and particular attention was paid to the aestheticization of politics to be found in versions of both MODERNISM and postmodernism (Harvey, 1989b).

More recently still, there been a renewed interest in Kant’s view of COSMOPOLITANISM set out in ‘Perpetual Peace: a philosophical sketch’ (1795). To some critics, it is frankly bizarre to juxtapose Kant’s essay with the ETHNONCENTRISM (at best) and at worst the ‘racisms and ethnic prejudices’ of his lectures on physical geography (Harvey, 2000a, p. 544). But Harvey also recognized that the ‘contrast between the universality of Kant’s
cosmopolitanism and ETHICS and the awkward and intractable peculiarities of his geography is important’ precisely because it opens a space for a crucial ‘DIALECTIC between cosmopolitanism and geography’ (Harvey, 2000a, pp. 535, 559). Other critics have mapped that space in radically different terms. Since the end of the Cold War, and even more insistently after 9/11, several hostile and usually (though by no means invariably) American commentators have described contemporary EUROPE as in thrall to Kant and his vision of ‘perpetual peace’, while leaving the USA the supreme task of bringing order to the Hobbesian world of ‘failed states’ and collapsing states, of warlords and transnational TERRORISM beyond its boundaries. That said, Elden and Bialasiewicz (2006, p. 644) argue that ‘the characterisation of a “Kantian” Europe, weak, complacent, and “out of touch” with current global realities, tells us more about the United States and its imagined role than it does about Europe’.

kibbutz A collective Zionist village. Over 250 rural kibbutz settlements (‘kibbutzim’ in the plural) have been established in Israel/Palestine since 1909. Kibbutz communities combine two ideals – SOCIALISM and Zionism. Until the 1970s, kibbutzim were considered the torchbearers of the Zionist project by embodying its main goals: colonizing, Judaizing and farming the contested frontiers, leading the Israeli army, and symbolizing the new national culture. The ‘kibbutznik’ became an icon of Zionist IDENTITY – the ‘new Jew’ – a strong, independent, settler–soldier. However, with the gradual decline of HEGEMONY held by Israel’s Ashkenazi (Western) Jews and Labor Movement, the special status of the kibbutzim has eroded. Today, most kibbutzim have become urbanizing villages, and have shed many of their socialist features. OY

knowledge economy An economic regime in which knowledge-intensive manufacturing and service activities become dominant, and in which the skill and expertise of workers and the INNOVATION that this facilitates lie at the heart of the success of firms, regions and national economies. The idea of a knowledge economy derives from Drucker’s (1969) account of the role of the ‘knowledge worker’ in manufacturing industries, and it has been developed through knowledge-based views of the firm and arguments about the centrality of knowledge to the competitiveness of national economies. The concept of a POST-INDUSTRIAL SOCIETY based on advanced, knowledge-rich services was also instrumental in attracting the attention of academics and policy-makers. From a policy perspective, the idea of the knowledge economy has been used to foreground discussions, in the Anglo-American world in particular, about the need to invest in skills development and training for workers, and to promote the shift towards advanced knowledge-intensive industries (OECD, 2000). These debates have often been tied to discussions of national competitiveness (Dunning, 2000), which tacitly assume a spatial DIVISION OF LABOUR in which the economies of Western Europe, North America and South East Asia act as ‘leaders’ in the knowledge economy, whilst less developed nations will fulfill less knowledge-intensive roles, particularly in manufacturing assembly processes.

Academic debates have addressed three main issues. First, Gregersen and Johnson note that ‘all economies are knowledge-based. Even so-called primitive economies depend on complicated knowledge structures’ (1997, p. 481). Consequently, discussion has recognized degrees of knowledge-intensity. Second, the REGIONAL GEOGRAPHY of the knowledge-economy has been foregrounded in analyses of CLUSTERS, LEARNING REGIONS, INDUSTRIAL DISTRICTS and innovative milieux. But Martin and Sunley (2003) remain unconvinced that the REGION is the appropriate SCALE of analysis, while others position regions within global NETWORKS of knowledge that include both the embodied movement of personnel and the virtual circulation of knowledge through global telecommunication systems (Amin and Cohendet, 2004). Third, considerable attention has been paid to the discursive effect of the concept itself (see DISCOURSE). Thrift (1997b) posits the contemporary emergence of a ‘soft CAPITALISM’, whose ideologies and practices powerfully shape the ways in which policy-makers use ideas of competitiveness and innovation associated with the knowledge economy. Thus Larner (2007) shows how the New Zealand government developed policies based on the logics of the knowledge economy to harness the expertise of expatriates and emigrants in
Kondratieff waves  A schematic representation of the major features associated with long-wave economic cycles (Knox and Agnew, 1989: adapted from Marshall, 1987)
order to improve competitiveness. Peck (2005) sounds a cautionary note, however, noting that discourses surrounding the knowledge economy and a supposed ‘creative class’ have led to the prioritization of the needs of workers with certain skill sets and the marginalization of nominally ‘non-creative’, ‘non-innovative’ workers in non-knowledge-intensive occupations (from cleaners to caterers to public transport operators), without which the knowledge economy cannot operate.

Kondratieff waves Cycles in economic activity in the world economy, with a wavelength of 40–60 years. Shorter oscillations may be superimposed over these long waves, but Kondratieff waves imply fundamental qualitative transformations through alternating sequences of growth and stagnation rather than mere quantitative fluctuations in economic activity (see figure on page 401). Soviet economist Nikolai Kondratieff (1892–1938) claimed to have identified long waves in the 1920s, and since then there has been considerable interest in and controversy over the connections between them and the dynamics of uneven development under capitalism. Mandel (1980) argues that there is a systemic relationship between long waves and capitalist restructuring, for example, while Maddison (1982) accepts the existence of major phases of capitalist growth but insists that these have been the result of ‘specific disturbances of an ad hoc character’. Scholars who accept a systemic relationship typically fasten on technological change: technical innovations often cluster during recessions, when they open the door to revived profits and to wider transformations in the labour process, regimes of accumulation and the like. On this basis, Kondratieff waves have been associated with technological revolutions (cf. industrial revolution) and sectoral growth – for example:

1. steam power and machinofacture in the textile industries;
2. the spread of railways and the growth of the iron and steel industries;
3. electricity, petroleum and the chemical and automobile industries;
4. electronics, synthetics and petrochemicals; and
5. information technology, telecommunications and biotechnology.

This is only an example; several different schemes have been proposed. Technical innovations are not only distinguished by periodicity, however, but also have distinctive geographies: spatial loci of experimentation and innovation, and networks of diffusion. The complex of changes represented by these cycles and phases thus has a profound impact on and is also deeply affected by geographies of production and reproduction (see, e.g., Marshall, 1987; Hall and Preston, 1988; Dicken, 2007). Some scholars have also proposed a close association between Kondratieff waves and the global geography of war (see, e.g., Goldstein, 1988; Devezas, 2006).
laboratory  A laboratory is a site of experimentation. Not simply a physical space where a certain sort of scientific research takes place, the full significance of laboratories can only be appreciated if they are understood as a very particular achievement. A historically specific configuration of people, practices, machines and measurements, the laboratory is organized as an arena in which – purified of the contingencies of the field – the truth of the matter-phenomena under investigation will supposedly reveal itself. As the privileged generator of the particular form of knowledge that is the scientific fact, laboratories are thus a source of great authority and potentially power, particularly if a network allowing the extension of its results elsewhere can be built and maintained (see also SCIENCE/SCIENCE STUDIES). labour geography  Straddling economic, political, social and cultural concerns, labour geography is now an established part of the geographical discipline. In its earliest manifestations, the sub-field was driven by an effort to highlight the agency of labour in making the landscape, most particularly through collective trade union organization. Rather than seeing labour as simply a factor in production, or even as an agent of a socialist dawn, labour geographers sought to document the ways in which workers’ organizations developed as part of the lived experience of PLACE. As such, trade union organization is understood as being co-constituted with place. As Herod, Peck and Wills (2003, p. 176) explain in a recent overview of the field and its relationship to industrial relations:

Axiomatic for labour geographers is the claim that spatial factors – such as the inescapably uneven geographical development of capitalist economies, the geographical scale and scope of legislation, the role of distinctive regional ‘cultures’ of industrial relations practices, the structure and dynamics of local labour markets, the spatial hierarchies of trade union organisation, the locally-differentiated processes of social reproduction, gender and race relations, the shifting landscape of political activism and labour-organisational capacities – really matter in the practice of industrial relations and in the trajectories of workplace politics.

Hence, labour geographers argue that we cannot understand matters of work, managerial cultures, trade union organization, local politics or culture without attention to geography. Moreover, recent work in this field has highlighted the extent to which trade unionism itself has its own geography: the organizational structures and strategies deployed reflect the politics of SCALE, past and present. In responding to the challenges posed by global NEOLIBERALISM, for example, trade unions are experimenting with new ways to find leverage and re-scale their organizations beyond the workplace to encompass COMMUNITY, regional and global dimensions (Herod, 2002; Savage and Wills, 2004; Hale and Wills, 2005).

As it has matured, labour geography has moved from its initial focus on trade union organization to speak to most of the significant debates in HUMAN GEOGRAPHY as a whole. What started as a polemical effort to put labour on the map of the discipline has become part of the mainstream. Labour geography continues to evolve, now encompassing research into matters such as LABOUR MARKETS, public policy in relation to employment and the labour market, and questions of work and IDENTITY (Castree, Coe, Ward and Samers, 2005). Contemporary research includes a focus on the dynamics of labour MIGRATION, the extent to which labour is able and willing to take its place in a multi-scalar CIVIL SOCIETY that includes the emergent global justice movement, the way in which CLASS and identity are changing, as well as questions of GLOBALIZATION and its implications for work, wealth and power relations. labour market  The geographical arena in which labour power is bought and sold – where those looking for work (workers) and those looking for workers (employers) find
each other. As such, labour markets are necessarily geographical (Martin, 2000b). These labour markets are often very local, including places such as the street corner where day labourers stand hoping for work or the town in which the local newspaper publishes adverts looking for staff. However, under conditions of neo-liberal GLOBALIZATION these transactions are being spatially stretched to incorporate MIGRANTS who might cross continents looking for work. Thus, the labour markets in some GLOBAL CITIES such as London are places where native-born Londoners are competing for jobs – at both the ‘top’ and ‘bottom’ ends of the occupational hierarchy – with workers from the rest of the world. Indeed, there is now a large literature exploring the complex labour markets of such cities and regions (May, Wills, Datta, Evans and Herbert, 2007).

Geographical understandings of the labour market were traditionally focused on mapping the geographical area from which workers travelled to work. As such, large urban conurbations often attracted workers from relatively far away, using the commuter transportation networks on which all cities depend. However, this approach to mapping the labour market tells us nothing about the POWER relations or the role of geography in the operation of labour markets. Labour power is a unique form of COMMODITY and in order to buy labour power, employers have to deal with the people who embody that power (Peck, 1996). As such, the labour market depends upon employers managing their workers through the LABOUR PROCESS in order to realize the commodity – labour power – that they buy. People come to work with their own personalities, expectations of work and political traditions, and the potential conflict between employers and workers is the root of trade union organization (see LABOUR GEOGRAPHY).

Such social relations also reflect the PLACE in which the labour market is grounded. Unequal opportunities to develop skills and different life experiences afford people varying potential to ‘sell themselves’ in the market for jobs; skills reflect previous opportunities for education, work and training, and the history of employment, in any location. As is well documented, workers in RUSTBELT regions that long depended on male manual work struggle to find work in the new service economy (see SERVICES). The changing nature of the economy demands new kinds of workers, with different physical and mental qualities (McDowell, 2003). There is often a spatial mismatch between the needs of employers and the needs of those looking for work, and workers find themselves being de-skilled or having to re-train in order to secure employment. As such, the labour market has a direct relationship to and impact upon the configuration of GENDER, ETHNIC and CLASS relations in and across space. Processes of direct and indirect discrimination in labour demand further accentuate these structural divisions in labour supply. Employers view potential workers through their own characterization of the ‘good worker’ and employees find themselves in segregated workplaces and jobs as a result. Jobs are gendered and women are still largely concentrated in part-time, lower status and lower paid work (McDowell, 2001). Jobs are similarly racialized and socially constructed as being better suited to men and/or women from particular ethnic groups. Thus, while many minority ethnic women are nurses in the UK, they face direct and indirect discrimination in securing employment in managerial grades.

In recent years, governments have turned their attention to the labour market in order to reduce welfare receipt and ‘make work pay’. In what has been called workfare, governments in many post-industrial economies have reduced welfare payments and/or developed active labour market strategies that demand evidence of job-search and training on the part of the unemployed. These policies have been developed without regard to the geography of labour demand or the cost of going to work. Governments have altered the supply of labour without concern for the quality of the jobs to be filled. As such, and despite national-level variations in legal minimum wages and statutory employment rights, there have been concerted efforts directed at labour market flexibility. A number of scholars have argued that these strategies are ideologically driven, seeking to create new sources of very cheap labour. As Peck puts it:

Stripped down to its labor-regulatory essence, workfare is not about creating jobs for people that don’t have them; it is about creating workers for jobs nobody wants. In a Foucauldian sense, it is seeking to make ‘docile bodies’ for the new economy: flexible, self-reliant and self-disciplining (2001, p. 6).

In countries such as the UK and the USA, these labour market policies are being augmented by efforts at managed MIGRATION, whereby workers are recruited to fill specific gaps in the labour market, often doing jobs that native workers are unwilling to do. This
drive for labour market flexibility has fuelled the growth of the working poor in many locations, and new forms of political resistance, such as living wage campaigns, are growing as a result.

labour process  The means through which labour power is extracted from workers: the phrase originates in MARXISM, though it refers more broadly to the organization of work. Be they in the field, factory or filing department, when workers are employed, they enter into a labour process through which their work is organized and surplus (which is realized as labour process through which their work is organized and surplus (which is realized as CAPITAL) is extracted. As such, writers who use this phrase are often doing so with a focus on POWER relations in the workplace: they have an interest in the relationship between managerial control, technologies of work, subjectivity and workers’ resistance. Research into the labour process exploded with the publication of Braverman’s (1974) Labor and monopoly capitalism, which suggested that the de-skilling of work was the dominant tendency in the capitalist MODE OF PRODUCTION. Geographers, however, played very little part in this subsequent explosion of work on de-skilling. Instead, these ideas about the labour process have been manifest in debates about spatial DIVISIONS OF LABOUR.

In her seminal work, Spatial divisions of labour, Massey (1984) highlighted the ways in which the drive for profitability leads corporations to reconfigure the geography of their operations, breaking up and stretching out the labour process across space. Thus, managerial functions tend to be separated from those of manual labour and, increasingly, companies have developed complex structures of production at global dimensions. In what have been called global COMMODITY CHAINS, many of the largest TRANSCONTINENTAL CORPORATIONS now take advantage of a complex and fast-changing international division of labour, using subcontracted production and service delivery companies to reduce costs, minimize risk and increase flexibility (Dicken, 2003; Hale and Wills, 2005). As such, the labour process has a very clear geography, in which the map of manufacturing and, increasingly, service industries (such as call centres) is organized at a global scale. The separation of control from production raises a number of important questions about responsibility and power. Workers are generally disempowered by this extension of corporate geography and the spatial reorganization of the labour process. As a result, trades unions are experimenting with new forms of internationalism and are attempting to forge alliances with consumers to find new sources of power (see LABOUR GEOGRAPHY).

Ultimately, geographers have sought to root understandings of the labour process in PLACE, highlighting the way in which the labour process changes social relations and political possibilities within and between different locales.

labour theory of value  A cornerstone of classical economics, prominent in the writings of Adam Smith and David Ricardo. The work of the French Physiocrats (notably François Quesnay and the elder Mirabeau) was a proximate influence on Smith’s formulation of a labour theory; more distantly, the writings of the proto-liberal philosopher John Locke, especially his Second treatise on government (1681), were a likely influence. In his moral-political theory, Locke defended the virtues of individual labour, the sanctity of property acquired by mixing labour with objects and the natural rights of individuals – and conceived for the STATE the limited but critical role of regulating and securing private PROPERTY (see LIBERALISM).

Why have a labour theory of value at all? For one, Locke’s version of the labour theory provided no indication of how to bring into equivalence different forms of private property within a generalized exchange economy. Adam Smith’s version of the labour theory attempted exactly that: his purpose was to demonstrate the ‘natural price ... [or] the central price, to which the prices of all COMMODITIES are continually gravitating’ (1991 [1776], p. 61), or in other words, their intrinsic worth above and beyond the ephemeral fluctuations of market price. This, of course, begged the question: Which commodity served as the natural basis of all others? During the early industrial era (see INDUSTRIAL REVOLUTION), it was tempting to infer that ‘labour’ was the common basis of all exchanged goods. But neither Smith, nor Ricardo, who adopted his labour theory, could resolve a basic contradiction; namely, what the natural price of labour should be.

Karl Marx made the breakthrough. He drew a distinction between the ‘use-value’ and ...
the ‘exchange-value’ of a commodity, and designated ‘labour’ as use-value and ‘labour-power’ – the actual commodity transacted between employers and employees – as ‘exchange-value’. This in turn allowed him to claim, without contradiction, that in a capitalist mode of production (see Capitalism), ‘labour-power’ as a commodity had both a market price and an underlying value, which was the socially necessary labour time necessary for its (re)production. Capitalists purchased ‘labour power’ in order to consume its use-value, ‘labour’, which had the unique capacity to produce more value than necessary for its reproduction – in short, ‘surplus-value’. Hence, in one fell stroke, Marx was able to resolve the contradiction that had plagued Smith and Ricardo, recuperate the labour theory of value, and provide a basis for capital accumulation as the accumulation of surplus-value. Notice that Marx did not seek a ‘natural price’ explanation; rather, he clearly inserted the adjective ‘socially necessary’ in order to indicate the geographical, historical and relational basis of value. Marx’s labour theory of value was subsequently attacked on several fronts, most persistently around its ostensible failure to systematize the relation of value, and provide a basis for capital reproduction – in short, ‘surplus-value’. Hence, in one fell stroke, Marx was able to resolve the contradiction that had plagued Smith and Ricardo, recuperate the labour theory of value, and provide a basis for capital accumulation as the accumulation of surplus-value. Notice that Marx did not seek a ‘natural price’ explanation; rather, he clearly inserted the adjective ‘socially necessary’ in order to indicate the geographical, historical and relational basis of value. Marx’s labour theory of value was subsequently attacked on several fronts, most persistently around its ostensible failure to systematize the relationship between value and market price – the so-called ‘transformation problem’.

Diane Elson’s (1979) innovative reading of Marx’s theory of value – which David Harvey endorses in Limits to Capital (1999 [1982]) – circumvents both the critique that Marx’s formulation stands – and falls – on labour being the physical substance of value as well as the transformation problem by arguing that what Marx really intended was to draw attention to the rationalizing practices whereby labour in a capitalist mode of production is continuously enrolled in abstracted form through the wage/money relation. This not only involves a disciplining of labour through surveillance, monitoring, punishment and incentive contracts; but, more pointedly, these mechanisms are to be themselves viewed as symptomatic of a system of generalized commodity exchange – that is, a dominant and more-or-less competitive market system – where wealth and worth are measured in an impersonal, abstract money form. Thus, a ‘value theory of labour’, as Elson presents it, is a condensed expression of the imperative for capitalists to constantly cut labour costs and raise labour productivity in order to survive, and for workers to become continuously more productive at their tasks in order to not become dispensable. In Elson’s words: ‘My argument is that the object of Marx’s theory of value was labour. It is not a matter of seeking an explanation of why prices are what they are and finding that it is labour [thus, Elson sidesteps the nettlesome ‘transformation problem’]. But rather of seeking an understanding why labour takes the form it does, and what the political consequences are’ (1979, p. 123).

Lamarckianism A theory of evolutionary change originating with the French naturalist Jean Baptiste de Lamarck (1744–1829). A non-Darwinian doctrine of organic progression, early Lamarckism differed significantly from its later Neo-Lamarckian successor. The dynamic behind Lamarck’s own scheme of evolution along separate lines of development, rather than by common descent, was the active power of nature (combining processes of environmental stimulus, the adaptive habits of organisms in adjusting to modified conditions, and the use and disuse of organs) to impel life along predetermined sequences (Burkhardt, 1977).

In the decades around 1900, when Darwinism was in eclipse as a consequence of a series of criticisms within the scientific community, the Lamarckian mechanism of the inheritance of acquired characteristics achieved considerable support as providing an alternative mechanism for evolutionary transformism (Bowler, 1983). This marginal component of Lamarck’s original scheme became the central plank in Neo-Lamarckian interpretations of evolutionary change, which routinely considered that those organic modifications on which natural selection operated were environmentally induced. Particularly in the USA, but also in Britain, this alternative evolutionary theory attracted widespread support during the second half of the nineteenth century despite the absence of agreed empirical corroboration. Particularly prominent were the palaeontologists Edward Cope and Alpheus Hyatt, the geologists Joseph LeConte and Clarence King, and the Duke of Argyll and George Romanes in anthropology and psychology. In France, the Societe Zoologique d’Acclimatation under Isidore Geoffroy St-Hilaire vigorously promulgated Lamarckism in projects on environmental adaptation that had implications for human migration and colonialism (Osborne, 1994). Most dramatic of all was the theory’s official endorsement in the
Soviet Union during the 1930s, where T.D. Lysenko used Lamarckism to justify his ideas about agricultural improvement and judged that it fitted more comfortably with Marxist political ideology than did classical neo-Darwinism. Like Darwinism, Lamarckism also had social implications. Indeed, many social evolutionists drew more inspiration from Neo-Lamarckian dogma than from standard Darwinism. For some, it provided grounds for looking to environment as the driving force behind social processes; for others, who were enthusiastic about the role it attributed to mind and will, it reserved space for psychic elements in evolution and thereby enabled them to escape the pessimism that gripped many at the beginning of the twentieth century. Either way, Lamarckism could be mobilized to justify the politics of social and political interventionism.

Given its various enthusiasms, it is not surprising that a number of geographers would find Neo-Lamarckism attractive, not least because the environment played such a key directive role in the scenario (Livingstone, 1992). In the USA during the late nineteenth and early twentieth centuries, numerous advocates of environmental determinism, such as Nathaniel Shaler, W.M. Davis, Ellen Semple, Albert Brigham and Ellsworth Huntington, displayed Lamarckian sympathies and used the theory to provide naturalistic readings of human culture. Similarly Turner’s Frontier Thesis, which portrayed American society as recapitulating the stages of social evolution with each advance of frontier settlement, drew inspiration from Lamarckian environmentalism (Coleman, 1966). Griffith Taylor in Australia found it equally attractive, though he did not discount the significance of Mendelian genetics (Christie, 1994).

In late-Victorian Britain, similar convictions are discernible among those sympathetic to Lamarckism’s emphasis on the significance of consciousness. Patrick Geddes used it to advocate various urban planning and educational reforms on the grounds that their benefits would accumulate, by social inheritance, in successive generations; Peter Kropotkin, critical of the cut-throat ethics of capitalist competitive struggle, found in Lamarckism the grounds for a more benign social order – a mix of Anarchism and Humanism – built upon mutual aid (Todes, 1989); and Andrew Herbertson and H.J. Fleure both mobilized the idea in their considerations of regional geography. Lamarckian motifs have also been discerned in Paul Vidal de la Blache’s possibilism.

More generally, Neo-Lamarckism facilitated geography’s transition from a natural theology framework to that of evolutionary naturalism largely due to the ease with which it could be given a teleological reading (Livingstone, 1984: see TELEOLOGY). Its impact on the evolution of geography around the time of the subject’s professionalization was thus very considerable (see GEOGRAPHY, HISTORY OF).

**land tenure** The practices through which land is possessed. Land tenure entails both formal property rules and rights, sanctioned by some collective, and more symbolic and culturally coded forms of, land attachment. Land, in particular, is both an object with use value, and a symbol endowed with meaning. Scholars of land tenure tend to emphasize the latter, noting the significance of complex, ritually reproduced relations of land-holding. Land is often spoken of as an active agent, encompassing the interests of the living and the dead. Rules governing access and use rights are embedded within complex and often highly localized lifeworlds (Hann, 1998). Land tenure should be distinguished from housing tenure – that is, the variegated ways in which people acquire rights in real property – hence the distinction between renters, private owners, leasehold tenants, and so on (see HOUSING CLASS).

Scholarship has tended to emphasize tenurial relations amongst peasant and hunter–gatherer communities, located in the premodern history of the West, or within the contemporary developing world. However, it should be noted that culturally laden and often collectively oriented forms of landholding can be found within the modern West, as noted by some of the contributions in Abramson and Theodossopoulos (2000).

Land tenure, as a means through which a place is known and represented, and a social order enacted and sustained, is clearly geographical. One interesting strain of scholarship concerns the ways in which landscape – as both a material and representational resource – connects to land tenure (Olwig, 2002). Another crucial dimension concerns systematic attempts at the remaking of land tenure, of which Western colonial displacements of indigenous property (see COLONIALISM), state collectivization or individualization of landholding, the enclosure of the commons,
and clashes between agrarian and hunter–gathering societies are all examples. The geographies of these often violent reworkings (Peluso and Watts, 2001), and associated forms of resistance (Peluso, 2005), have been compellingly documented.

land use and land-cover change (LULC) A component of contemporary studies of global environmental change that focuses on both land cover (i.e. the land’s physical attributes, such as forest, grassland etc.) and the purpose for which those attributes are used and/or transformed by human actions. Large-scale international research programmes into land cover (making extensive use of data obtained via remote sensing) have been undertaken recently under the auspices of the International Geosphere–Biosphere Programme and related institutions. The goal is not only to establish the nature and pace of land-use cover change, at a variety of scales, but also to understand its causes, thereby facilitating modelling of likely future change, in the context of searches for sustainable development (cf. sustainability).

landscape A cardinal term of human geography, landscape has served as central object of investigation, organizing principle and interpretive lens for several different generations of researchers. Through periods of both ascendancy and eclipse, landscape’s constancy lies in its function as a locus for geographical research into culture–nature and subject–object relations.

The etymology of the English word ‘landscape’ is complex. Many sources (e.g. Jackson, 1984; Schama, 1995) refer to the Dutch word landschap as having migrated into English usage through the sixteenth and seventeenth centuries, with ‘landscape’ gradually coming to refer to both the visual appearance of land, most often countryside, and its pictorial depiction via perspectival techniques for representing depth and space. The association of landscape with visual art, and with rural or natural scenery, is cemented in its contemporary colloquial definition as, (a) a portion of land or scenery which the eye can view at once, and (b) a picture of it.

In partial contrast, Olwig (1996) notes that the Old Dutch landskab and the Germanic landschaft both also connote legal and administrative notions of community, region and jurisdiction: landscape as customary administrative unit. Landschaft was also the term adopted by American geographer Carl Ortwin Sauer (1963b [1925]) in his seminal monograph The morphology of landscape. This sought first to establish a definition of geography as a field science of landscape and, second, to define landscape itself in terms of interactions between human cultures and natural environments (see morphology). Thus landscape was conceived as a cultural entity, the distinctive product of interactions between people and topography. Sauer’s argument that ‘culture is the agent, the natural area is the medium, the cultural landscape the result’ (1963b [1925], p. 343), oriented several decades of American cultural geography towards the historical reconstruction of cultural landscape forms through fieldwork and archival study.

However, Richard Hartshorne’s (1939) influential The nature of geography notably critiqued landscape’s incorporation of both objective and subjective elements (the land and land-as-perceived), concluding that the term could not serve as the basis of a properly scientific geography. The subsequent rise of regional and then spatial science paradigms following the Second World War thus saw something of a decline in landscape’s purchase and salience as an organizing term for human geographers. In this period, most notable and innovative geographical writing on landscape appeared the journal Landscape, founded in 1951 by J.B. Jackson. Through his own extensive writings, Jackson defined landscape in terms of the material world of ordinary everyday or ‘vernacular’ life – in postwar America an often-bypassed world of garages, motels, neon-lit strips and backyards. Jackson’s writing also extended the empirical emphasis of Sauerian cultural geography through attending seriously to the symbolic and iconic meanings of landscape. This vision of landscape as at once an everyday, lived-in world and a repository of symbolic value chimed with the agenda of North American humanistic geography in the 1970s, and found its clearest expression in a volume of essays on The interpretation of ordinary landscapes (Meinig, 1979).

A raft of innovative writing on landscape emerged in the late 1980s and early 1990s, constituting a significant element of the cultural turn in Anglo-American human geography as a whole. The work of Denis Cosgrove (1998 [1984]) and Stephen Daniels (Daniels and Cosgrove, 1988) in particular advanced an influential definition of landscape as a way of seeing and representing the world.
Here, landscape was largely equated with Western visual traditions of landscape painting and gardening. In drawing upon and extending the work of cultural Marxist critics such as John Berger (1972) and Raymond Williams (1973), these cultural geographies of landscape focused upon the critical interrogation of the ideological function of landscape images, arguing that landscapes worked so as to reflect and reproduce the values and norms of socio-economic elites. In pinpointing its Italian Renaissance origins, Cosgrove (1985) sought to highlight the complicity of landscape as a way of seeing with notions of objective knowledge and distanced visual authority and control. In speaking of landscape’s ‘duplicity’, Daniels (1989) noted that the aesthetic function of artistic landscapes masked their ideological role in naturalizing socio-economic hierarchies and patterns of land ownership (see ART; ICONOGRAPHY). In defining landscape as a text to be critically read via the principles of structuralist semiotics, Duncan and Duncan (1988) argued that landscape operated as a signifying system for the production and transmission of cultural meanings.

Gillian Rose (1993) further extended and critiqued this body of work through highlighting how, for geographers and others, the landscape way of seeing was a particularly masculinist gaze. Thus, in addition to systems of cultural and political power and capitalist forms of social relation, landscape visually indexed specific forms of patriarchy and disembodied, detached observation. For Rose, the academic landscape gaze involves a duality between an active masculine eye and a passive, ‘naturalized’ femininity. This eye, however, oscillates ambivalently between asserted rational observation and repressed visual pleasure, in the form of voyeurism and narcissism. This critique thus applied psychoanalytic principles to landscape interpretation, further aligning cultural geographies of landscape with work in visual and cultural theory (e.g. Mulvey, 1989; Nash, 1996: see VISION AND VISUALITY).

Work through the 1990s sought to inflect and extend the cultural turn focus on landscape images and texts by further apprehending landscape in terms of action, process and movement, both discursive and material. Don Mitchell’s (1996, 2003) materialist analyses aim to re-invigorate Marxist understanding of landscape in terms of production as well as the cultural consumption and circulation of landscape imagery. For Mitchell, the production of actual, material landscapes such as mining towns or agricultural belts is a matter of ongoing struggle and conflict between different social and economic groups within capitalist networks of violence, inequality and profit. With a similar focus upon issues of power, but in a more discursive and interpretative vein, an influential collection edited by cultural theorist W.J.T. Mitchell (2002e [1994]) sought to define landscape as a verb, not a noun – that is, as a process, not an object or image. Here, understood in terms of culturally specific styles of moving, seeing and representing, landscape is historically identified with European imperial discourse, the visual modus operandi of European explorers, artists and cartographers. Extending the focus of earlier work upon landscape in national contexts, linkages between the landscape gaze, science, exploration and imperialism have been extensively discussed by cultural geographers and historians (see Pratt, 1992; Ryan, 1996; Clayton, 2000).

A further distinctive strand of current geographical writing on landscape, closely associated with the work of David Matless (1992, 1998), places emphasis upon cultures of landscape, most often in a British context. Drawing upon Michel Foucault’s accounts of discourse, power and subjectivity, landscape practices such as walking, boating and driving are analysed here in terms of the discursive regimes (e.g. those of health and citizenship, state planning, environmental activism), through which codes of proper conduct for using, appreciating and indeed creating landscape are elaborated.

Although these various discursive, iconographic and interpretive approaches have defined cultural geographies of landscape since the 1980s, they have of late been challenged, modulated and to some degree superseded by work advocating phenomenological, corporeal and performative perspectives. The cultural anthropologist Tim Ingold (1993, 2000) in particular has argued that the definition of landscape as a way of seeing perpetuates a duality of culture and nature, and erases first-order issues of materiality, agency and embodied performance by locating landscape within a disembodied realm of cultural discourse and signification. Ingold’s remedy proposes a landscape phenomenology, inspired by the writing of Martin Heidegger and Maurice Merleau-Ponty, and focusing substantially upon embodied practices of dwelling and being-in-the-world. Here, landscape is defined as a processual, material and perceptual engagement of body and world, enacted in terms of a distinctive temporality – a rich duration of inhabitation. This emphasis on bodily
performance and perception is further developed in recent work on landscape from interpretive archaeology and performance studies itself (Shanks and Pearson, 2000; Tilley, 2004).

Albeit with reservations regarding both the ontological principles and topical orientations implied by terms such as ‘dwelling’, phenomenological and performative studies of landscape, practice and perception have emerged strongly in human geography in recent years; for example, in writing focusing on issues of inhabitation (Hinchcliffe, 2003), mobility (Cresswell, 2003), biography and memory (Lorimer, 2003) and embodied perception (Wylie, 2002a). While there has been no wholesale rejection of the critical agendas and positions associated with work on landscape as a way of seeing, Mitch Rose (2002a) has cogently identified the epistemological difficulty of, on the one hand, presenting landscapes as already ideologically structured, while, on the other, paradoxically retaining subjects with the ability to flexibly inhabit and interpret landscapes. At the same time, the development of actor-network theory and hybrid geographies has arguably created a lacunae within landscape studies, through providing an alternative conceptual platform from which culture–nature issues may be apprehended. Most recently, however, in an attempt to address this lacunae, the task of producing a ‘post-phenomenological’ account of landscape has been identified, supplementing the work of writers such as Ingold by attending to self-landscape relations via ideas of affect and narrative (Wylie, 2005) and Derridean conceptions of presence and care (Rose, 2004b).

**Landschaft** A German term roughly corresponding to the English ‘landscape’. The scenic, pictorial and aesthetic connotations of the latter are downplayed, however, and Landschaft is instead more usually associated with attempts by nineteenth- and twentieth-century German scholars to fashion geography as a ‘landscape science’ engaged in the task of identifying and classifying distinctive natural and cultural regions. In Anglophone geography, the term Landschaft is closely connected with the work of Carl Ortwin Sauer and the Berkeley School. Sauer (1963a[1925]) in part adopted and modified the Landschaft approach in the development of his own morphological approach to landscape, placing greater emphasis upon the role of human agency and culture in shaping (as well as being shaped by) landscape.

Sauer (1963a [1925], ch. 16).

**land-use survey** The investigation and cartographic representation of land use. Large-scale surveys were launched in the UK in the 1930s by Dudley Stamp (1898–1966), based on extensive fieldwork and widely used as a land-use planning tool for several decades. Most surveys now deploy remote sensing and geographic information systems for data collection, collation, display and analysis (cf. land use and land-cover change).

Stamp (1946).

**language** Study of the changing distribution and social usages of language (including dialect/ idiolect) is an enduring yet varied tradition in human geography. Broadly, two main themes may be distinguished. In the first – the geography in and of language – attention focuses on studying language distributions, upon spatial and social variations in linguistic form and in the origins of and changes in place names. In the second – the language in and of geography – consideration is given to the connections between language, social power and identity and the practice of geography. Although it is not appropriate to see these two themes as mutually discrete, chronologically distinct or methodologically separate, the first is more securely rooted in certain traditions of cultural geography, the second more a feature of cultural politics and post-colonialism and contemporary interests in unequal power relations and in language as a political agency (see also discourse; qualitative methods; rhetoric).

The mapping of language areas, often in association with ethnicity, has been an established feature of anthropogeographical work since the nineteenth century (see anthropogeography). Here, language is treated as a cultural artefact, its changing distribution a reflection of the world’s shifting linguistic mosaic (and Anglicization: see Crystal, 2003), its study evident in what has been variously termed language geography or language mapping. In linguistic geography (sometimes termed dialect geography), the emphasis is upon local differentiations within speech areas, the variable distribution of given speech forms or the political authority and cultural identity.
rooted in certain languages (geolinguistics). In many such studies (but not all), the geography of language in such terms is a form of HISTORICAL GEOGRAPHY (e.g. Withers, 1984). Attempts to reverse language decline or obsolescence may involve direct language planning. Attention to the language in and of geography is more concerned with the study of language as the medium through which inter-subjective meaning is communicated, and in the power relations intrinsic to such meaning. Thus understood, interest in the role and nature of language within geography is part of the ‘linguistic turn’ within twentieth-century philosophy and social theory. It is evident in work on the politics of language, in the connections between spoken and written languages and authorial power, in attempts to ‘recover’ or do interpretative justice to others’ words and worlds in quantitative methodologies (e.g. Crang, 1992), in a recognition that the limits to our understanding of the world may indeed be the limits of our language (e.g. Farinelli, Ollson and Reichart, 1996) and, for some, in practices of resistance to an Anglo-American hegemony within geography evident in the dominance of English as the discipline’s lingua franca (e.g. Braun, 2003; Desbiens and Ruddick, 2006; see ANGLOCENTRISM). Latin America In conventional usage, the term refers to those countries of the American continent that share a history of Spanish, Portuguese and French colonialism. However, the term also is widely used to denote all countries south of the USA (Lewis and Wigen, 1997, p. 182). The term’s ambiguity has led to academic disputes over how the category is defined and which countries properly belong within it. For instance, Quebec is not included, despite a history of French colonialism; nor are the Mexican states annexed by the USA in 1848. The problem with such debates is that they presume a natural congruence between geographical categories and an underlying social reality, which can be accurately mapped. Obscured are ontological questions concerned with how categories are constituted through intersecting DISCOURSES and interlocking POWER-GEOMETRIES.

Since its inception, the term ‘Latin America’ has been tangled in colonial and post-colonial contests over identity and territory (Mignolo, 2005). John Phelan (1968) attributes the term to nineteenth-century French scholars, who positioned France as the leader of a Latin ‘race’ engaged in a struggle for domination against Anglo-Saxon and Slavic racial blocs. According to Phelan (1968, p. 296), the term ‘Latin America’ was baptized in 1861 in La revue des races Latines, a magazine ‘dedicated to the cause of Pan-Latinism’. Theories of Pan-Latinism were called upon to naturalize attempts by Napoleon III to expand imperial power in what was then commonly called Hispanic America.

However, the idea of pan-Latinism also circulated in Spain and Hispanic America in the mid-nineteenth century, as intellectuals from the Creole elite expressed anxiety about the imperial ambitions of Anglo-Saxon America (Ardao, 1992). Chilean scholar Miguel Rojas Mix (1986) attributes the term to Francisco Bilbao (1823–65), an exiled Chilean writer living in Paris in the mid-nineteenth century. According to Rojas Mix, Bilbao used the term in a speech in 1856. Arturo Ardao (1992) credits the Colombian writer José María Torres Caicedo (1830–89), also living in Paris, with its christening in 1856 in his poem ‘The Two Americas’. In any case, both authors used the term to delineate fundamental cultural and political distinctions between a Latin America characterized by spirituality and a quest for independence versus a materialist, individualistic and imperialist Anglo-Saxon America. With the US invasion and dismemberment of Mexico in mind, Bilbao, Torres Caicedo and others echoed Simon Bolívar in calling for a union of South American nations to detain the imperialist interests of the USA.

According to the Oxford English Dictionary, the term ‘Latin America’ appears in the USA in 1890, the year of the First International Conference of American states, held in Washington, DC. A precursor to the Pan-American Union, the conference led to increased academic interest in the countries south of the Rio Grande. The first academic course on ‘Spanish American History and Institutions’ was offered at the University of California in 1895 (Hanke, 1964, p. 10). In 1917 the Encyclopedia of Latin America was published, with a foreword from the then Director General of the Pan American Union, who suggested that the spread of ‘accurate information will serve Pan American solidarity and community of action and purpose’ (Wilcox and Rines, 1917, p. 4). His message explicitly positions ‘Latin America’ as an important object of study at a time when the USA sought to bring the region in line with its policies; here, knowledge is made a key instrument of geopolitical power.
Drawing from Edward Said’s understanding of orientalism, Mark T. Berger (1995) argues that ideas about Latin America in the USA are inseparable from and the effect of US imperialism in the region. Berger elaborates this argument along three lines. First, he points to the blurred boundaries between the state and Latin American studies. Not only have academics moved back and forth between academia and the various agencies of the government, but the state has also attempted to shape the kinds of research undertaken. Hence, ideas about Latin America tend to reflect and constitute state interests. For example, Santana (1996, p. 459) illustrates how US-based geographical interests. For example, Santana (1996, p. 459) illustrates how US-based geographical researchers in Puerto Rico advanced a theory of ‘non-viability’, suggesting that the island was ‘not viable as an independent state’. Such studies were used to support arguments for continued US occupation.

Second, Latin American studies scholars have used organizing concepts that facilitate reductionism and allow the region to be analysed as a coherent unit. This is especially true after the Second World War, when the US government began to promote area studies. In the newly conceived world region framework, the term ‘Latin America’ replaced ‘South America’ (Martin and Wigen, 1997, p. 162). Area studies presumed the existence of coherent, naturally bounded regions, wherein human–environment relations had produced unique cultural groups. Contemporary regional geographies of Latin America continue in this tradition by seeking to delineate the core cultural traits organizing the region. Thus, Clawson’s (1997, p. 7) textbook defines Latin America as a ‘cultural entity’ bound by ‘a common Latin, or Roman, heritage’. Clawson identifies the core as that area where Latin or Hispanic culture is dominant: in fringe areas such as the US Southwest and the Caribbean, ‘traditional Hispanic values are largely missing’. Such demarcations between what properly belongs inside and outside a region are deeply problematic, for they obscure differences within nations and render invisible the interconnections and interdependencies between them.

Third, Latin American studies tend to use the USA as the frame of reference or benchmark for encoding representations of, and measuring the material progress in, Latin America (Berger, 1995; Schoultz, 1998). As a result, academic knowledge tends to be underwritten by a United Statesian–Self/Latin American–Other binary, which constitutes difference and distance within a hierarchical framing. No matter the theoretical approach used in the USA, from environmental determinism in the 1930s to area studies, regional geographies and development studies from the 1940s on, Latin America is conjured to embody everything that the USA is not: handicapped by climate and geography, isolated, backward, traditional, violent, peripheral, underdeveloped and poor. Such imaginative geographies are called upon to authorize or legitimate US intervention in the region, whether to protect national interests or foster development (Santana, 1996).

When the term ‘Latin America’ began to have broad circulation in English and Spanish in the early decades of the twentieth century, some Spanish intellectuals decried its use. Writing in 1918, Ramón Menéndez Pidal complained that the term deprived Spain of its historical and geographical titles in the New World (Ardao, 1992, p. 17).

South of the Rio Bravo, the idea of Latin America has conjured ambivalence and passionate attachment. For Daniel Mato (1998), the continuing salience of Latinoamericanismo stems from its association with nationalist, anti-imperialist struggles. Thus, for example, Alonso Aguilar (1968, p. 30) contrasts the US vision of Pan-Americanism with the ‘Latin-Americanism of Bolivar, San Martin, and Morelos which stood for the struggle of their people for full independence’. Appropriating such associations, ruling elites and state bureaucracies, Mato argues, repeatedly constitute and address a pan-ethnic group called Latinoamericanos to advance nation-building projects founded upon the myth of mestizaje (‘racial mixing’). For instance, in ¿Existe América Latina?, Luis Alberto Sanchez (1945, p. 239) suggests that the future of the region depends upon accepting mestizaje in a positive sense, as integration and creation. In Mato’s view, the notion of a mestizo ‘extended ethnic group’ perpetuates the exclusion of indigenous and African-descendent peoples.

The idea of Latin America has come under intense public criticism since the Columbus Quincentennial in 1992. While state officials planned elaborate celebrations – many funded by the Spanish government – indigenous and Afro-Latin American groups took to the streets throughout the region in an organized effort to posit alternative perspectives on the conquest and its aftermath. The increasing political power of such groups calls into question hegemonic views of the region’s Latin heritage, which work to obscure the contributions of indigenous and African-descendent peoples, as well as the
many other immigrant groups involved in producing the cultural landscapes of the Americas. Since the 1990s, a number of Latin American countries have ratified new constitutions recognizing their multicultural foundations. In this context, a number of indigenous social movements have formed viable political parties.

Currently, social movements in Latin America are fostering new geographical imaginaries to contest the US-driven Free Trade Area of the Americas, which would unify all of the Americas under a single free trade agreement promising to benefit transnational corporations. Hugo Chavez’s Bolivarian alternative for the Americas aims to create a socially oriented trade bloc built upon effective mechanisms to eradicate the economic disparities that exist within and between countries.

LAW
An enforceable body of rules and related norms governing social conduct. Geographers have long been interested in law, defined more or less broadly. Historically, analyses tended to divide into those, such as Ellen Semple, who sought to ground law in place, and others, like Derwent Whittlesey, who focused on what he termed the ‘impress of effective central authority upon the landscape’. Whether law is explained by reference to space, or space seen as produced by law, the tendency was to impose separations on law, space and society. From the 1980s onwards, when the ‘spatial turn’ in social theory made such a separation untenable, such binaries came under attack. Influenced by debates within social and legal theory, critical legal geographers have developed a very different reading of law, space and their mutual relation, with scepticism towards existing legal structures and the social relations that they embody. The distinguishing feature of this perspective is its refusal to accept either law or space as pre-political or as the unproblematic outcome of external forces. Both are regarded as deeply social and political. Law is seen both as a site in which competing values, practices and meanings are fought over, and also as the means by which certain meanings and social relations become fixed and naturalized, either in oppressive or potentially empowering ways. Law is understood not only as a set of operative controls, but also as a powerful repertoire of cultural and political meanings. Similarly, space is regarded as both socially produced and as socially constitutive, with attention being directed to the ‘politics’ of space. The relation between law, space and society is redefined and extended in important ways, opening up many new areas to critical geographic enquiry. This scholarship is remarkably diverse and lively, engaging with topics such as nature, landscape, state practice, nationalism and boundaries. Scholars draw from a range of theoretical sources, including queer theory, urban political economy, actor-network theory and cultural studies. Scholars also work across a range of scales, addressing not only national law (in relation to civil rights, crime, employment and housing, for example) but also international law (in relation to genocide, human rights, the laws of war and spaces of exception). Though fluid and non-institutionalized, some foci of interest over the past decade have included the following:

1. The analysis of the manner in which legal action and interpretation produces certain spaces. The role of the legal apparatus – especially the judiciary – is often given prominence, it being noted that court decisions have profound (and often problematic) effects within local settings in both material and discursive terms, given the manner in which legal categories and discourse can come to frame local debates (cf. Forest, 2001).

2. The related study of the situated nature of legal interpretation, it being argued that legal practice and interpretation is often bound up in the place in which it occurs (cf. Cooper, 1998; also situated knowledge).

3. The study of the geographical claims and representations (see representation) contained within legal discourse: in much the same way that law relies on claims concerning history and time, so it both defines and draws upon a complex range of geographies and spatial understandings. The construction of such spaces can be seen, for example, in relation to the designation of boundaries between private and public spheres (Pratt, 2004), struggle over the meanings of ownership and property rights (Blomley, 2004a) or conceptions of jurisdiction (Ford, 1999).

While insightful, scholarship on law and geography requires further development. While empirical accounts abound, the theorization of
the geographies of law and legal struggles is still undeveloped and somewhat ambiguous. Pressing questions include: What analytical and ethical difference does space make to the analysis of law? What sort(s) of power is law? How can space and law be brought together without succumbing to a binary logic? Are legal geographies only discursive? Finally, the ‘critical’ aspects of this enquiry need to be worked through more carefully. Some years ago, Vera Chouinard (1994a, p. 428) called for ‘meaningful political action in and against the legal system’. While this has been embraced in some quarters (Razack, 2002; Mitchell, 2003a), the political edge to critical legal geography remains undeveloped. Whether this entails intellectual challenges to legal ‘closure’ or grounded and inclusionary research projects concerning law remains an important question.

law (scientific) A statement of an invariant relationship holding between different phenomena, or between different states of the same phenomena. The best known formulation is found in orthodox philosophy of science and is represented in symbolic form as ‘If A, then B’. Boyle’s Law, for example, states that if the volume of gas at a given temperature increases, then pressure decreases proportionately. Similar law-like statements have been proposed for geography, of which perhaps the best known is Tobler’s (1970, p. 236) First Law of Geography: ‘Everything is related to everything else, but near things are more related than distant things.’ In the orthodox rendering, scientific laws are presumed eternal, universal, absolute, true and capable of expression in formal terms. They form the basis of scientific explanation and prediction – ground zero for understanding how the universe works. Two major objections have been levelled against these conventional views. First, realism argues that the orthodox ‘If A, then B’ form of a law says nothing about causality, instead asserting only the (weak) relation of conjunctural association. A stronger statement is required assigning causation. Second, work in science studies disputes many of the characteristics attributed to scientific laws by arguing that they represent local knowledge rather than universal knowledge, and ex-post rationalization rather than fundamental explanation. In this spirit, Barnes (2004a) draws on science studies to contest Tobler’s First Law of Geography.

law of the sea On 10 December 1982, the third United Nations Convention on the Law of the Sea (UNCLOS III) was opened for signature in Montego Bay, Jamaica, marking the culmination of over 14 years of work. More than 150 countries participated in drafting the treaty (representing all regions of the world, legal and political systems, and degrees of socio-economic development, and including coastal, archipelagic, island and landlocked states, as well as states ‘geographically disadvantageous with regard to the ocean space’; see Friedheim, 1993). The Law of the Sea entered into force on 16 November 1994. As of 16 March 2005, the number of parties to UNCLOS III, including the European Community, stood at 149 – 130 coastal and eighteen landlocked states.

The treaty aims at ensuring peace and security in the world’s oceans; promoting equitable and efficient utilization of their resources; and fostering protection and conservation of the marine environment. Equally significant is its role in clarifying and balancing the rights and duties of coastal states regarding adjacent maritime areas. Several ‘mini-packages’ of delicately balanced compromises emerged from the lengthy negotiations. For example, the convention allows coastal states certain rights in the ‘exclusive economic zone’ (Articles 55–75) – up to 200 nautical miles – for the purpose of economic advantage, notably rights over fishing and exploitation of non-living resources, as well as the concomitant limited jurisdiction in order to realize those rights. At the same time, however, neighbouring landlocked and geographically disadvantaged states must be allowed access to those resources of the zones that the coastal state does not exploit.

The LOS reserves the seas and ocean for peaceful and co-operative purposes, but regional conflicts, illegal activities (piracy, maritime terrorism and drug smuggling), competitive and unsustainable exploitation of marine resources, and environmental degradation are undermining human security at an alarming pace. Despite the obvious importance of polar maritime areas, there is a lack of general international law rules or conventions dealing with polar law of the sea problems (Chaturvedi, 2000). The LOS raises difficult questions in the following areas: ice-covered waters, polar
baseline, maritime zones and the deep-sea, high-sea freedoms and navigation, and marine pollution and environmental protection. The international community continues its efforts to strengthen the international legal framework to prevent and suppress acts of terrorism (including acts at sea), safety of navigation, maritime security and the protection of marine environment. The 1995 United Nations Fish Stocks Agreement, considered the most important multilateral legally binding instrument for the conservation and management of high-seas fisheries since the conclusion of UNCLOS III, calls upon states to establish new regional fisheries management organizations where none exist in a particular region or sub-region. Its objectives are to ensure the long-term conservation and sustainable use of straddling and highly migratory fish stocks and to protect marine biodiversity.

Learning regions Spatial clusters of linked industries whose continued growth is a function of permanent innovation, through inter-firm co-operation and competition. Agglomeration economies were first associated with industrial districts by the economist Alfred Marshall (1890) and the role of innovation in spatially proximate linked networks of firms is usually associated with the work of Piore and Sabel (1984), who stress that the importance of both formal and informal linkages within a cluster mean that the whole is more than the sum of its parts because of both the local ‘industrial atmosphere’ and the ‘mutual knowledge and trust’ resident there. Scott (2006) uses the alternative term creative field to describe the social relations within such a cluster, defining it as ‘all those instances of human effort and organization whose spatial and locational attributes, at whatever scale they may occur, promote development and growth-inducing change’ (p. 54). Recognition of the importance of such fields to the development of clusters such as Silicon Valley in California has stimulated many public policy initiatives aimed at creating and fostering learning regions – as with science parks.

Lebensraum Literally translated as ‘living space’, the term was used by Friedrich Ratzel in his representation of the state as an organism to identify a ‘geographical area within which living organisms develop’ (see anthropogeography). The term was developed by the Geopolitik school and partially adopted by the Nazis to justify the extension of the borders of the German state eastwards for the benefit of Germans and at the expense of the Slavs, who were represented as inferior and ‘unworthly’ of the territory (Smith, W.D., 1986; Clarke, Doel and McDonough, 1996). Territorial expansion was represented as a ‘natural’ consequence of the survival of the fittest (cf. Darwinism).

Smith, W.D. (1986b)

Leisure Either freedom from doing some things, or freedom to do other things – both definitions connote an existential state that involves pleasure and enjoyment, alongside choice. In many definitions and surveys, it is construed as activities that are not biologically necessary, that are not constrained by demands of work or other social actors, but that are chosen for personal pursuits. Much analysis has looked either at the changing ways in which ‘leisure’ intersects with other activities or at the changing forms of leisure activities themselves. The first approach thus looks at how leisure fits into the mix of activities that make up life. The most influential founding work in this regard is Thorsten Veblen’s Theory of the leisure class (first published in 1899). In it, Veblen sees leisure as a positional good that shows relative status and power within a system of consumption. For Veblen, ability to consume leisure was a signal of wealth and status. This was set within the context of long struggles in the later nineteenth and much of the twentieth century between labour and capital over reductions in the working week and paid holiday time. Considerable argument has emerged over whether the deregulated economies beginning in the late twentieth century, with demands for 24/7 services, have reversed that trend (e.g. Schor, 1991) or whether people feel more stressed, and leisure is more structured, but may have increased. All these studies focus on the amount of leisure time. However, difficulties arise about definitions when one considers forms of leisure that involve ‘serious leisure’, such as volunteering or educational hobbies (Stebbins, 1992), or social reproduction, such as cooking or eating, which may be for pleasure as well as necessity. These latter highlight gender issues in definitions, and that men in developed countries enjoy far more choice than do women with what to do with time that is free from paid work.
The second approach focuses upon the nature of leisure activities. This approach points to the significance of leisure both economically and in shaping personal identities. Classic critical theory argued that nothing was as abhorrent to capitalism as ‘free time’ and that leisure was its commodification into a product to be bought and sold. Originally, criticism focused on the Fordist mass production of homogeneous leisure products. Adorno and Horkheimer, in the Dialectic of the Enlightenment, argued that amusement under late capitalism is the prolongation of work ... mechanization has such a power over man’s leisure and happiness, and so profoundly determines the manufacture of amusement goods, that his experiences are inevitably after-images of the work process itself. (1979, p. 137)

Later work has argued that in a post-Fordist or postmodern world these patterns fragment and their meaning changes. Thus many analysts point to the emergence of social groups defined not by work identities but by shared leisure activities, such as different kinds of music or skateboarding, as subcultures or neotribes (Maffesoli, 1995). Others point to the emergence of a service-led ‘experience economy’, where we move from selling tangible products to consuming the memory of an event or experience (Pine and Gilmore, 1998). MC

Liberalism The view that individual freedom should be the basis of human life. Liberals believe that human well-being is maximized when individuals are free to pursue their own interests provided that doing so causes no harm to others. According to classical liberalism, the state should be as small as possible and only as strong as is necessary to maintain the conditions that will safeguard individual liberty. Liberal models of citizenship thus emphasize the formal equality of all citizens, civil rights, the rule of law and the protection of individuals from the arbitrary exercise of state power. Much debate within liberalism has been concerned with how to deal with conflicts of interest between individuals. Liberal models of democracy emphasize the expression of individual preferences through voting. In economics, liberalism favours private ownership and production and market mechanisms of resource allocation, based on the non-coerced interactions of individual producers and consumers.

Liberalism has been highly influential. All the world’s major industrialized countries are, formally at least, liberal democracies with market economies. In practice, however, their political institutions and economic systems rarely come close to liberal models, and in many places even basic civil rights are under threat in the name of the ‘war on terror’. The governments of some other countries, most notably China, have explicitly eschewed liberal democracy, although market mechanisms have been widely adopted in the economic arena.

Despite its apparent global hegemony, liberalism has been subject to many critiques and challenges (see, e.g., anarchism; communism; environmentalism; fascism; feminism; Marxism; post-colonialism; socialism). According to some contemporary defenders of liberalism, religious fundamentalism (see religion) poses the principal political threat to liberalism in the early twenty-first century. For others, there are inherent limits to liberalism and it is time to chart the contours of post-liberalism (Gray, 1996) or to push the democratizing impulse in liberalism in more radical and pluralist directions (see radical democracy).

Geographers have contributed to debates about liberalism in numerous areas. Much research has focused on neo-liberalism: the widespread revival of liberal economics since the 1970s and its application to public policy by national governments and international organizations (Harvey, 2005). Work on geographies of the body has questioned the concept of the sovereign and autonomous individual. Geographers have also engaged extensively with debates about rights and citizenship, focusing on the differential socio-spatial distribution of rights and obligations. The fundamental liberal distinction between the private and public spheres has been destabilized by geographical research into the fluidity and porosity of the public/private boundary. The universalizing imperatives of liberalism have been challenged by geographers charting the geopolitics of humanitarian and military intervention (Smith, 2006b).

Studies of the geographies of governmentality have revealed how liberal governance involves what Nikolas Rose (1999c) calls ‘powers of freedom’. In this view, freedom is a mechanism of governance, rather than its antithesis. JPa

life expectancy  The additional number of years of life that individuals who reach a certain age can anticipate. It is calculated by using current data on MORTALITY and making assumptions about future trends in growth rates within the framework of the LIFE TABLE. Life expectancy is most often reported for individuals at age zero (i.e. at birth) and shows marked variation over space and time, and by sex and ETHNICITY/RACE (Shaw, Davey and Dorling, 2005). Such variations are linked to the access that individuals and groups have to economic, social and political resources, making life expectancy a surrogate measure of SOCIAL JUSTICE within society (e.g. the human development index compares overall well-being between societies and is calculated using life expectancy, measures of knowledge and standard of living).

life table  An accounting framework that shows how many persons die before, and survive beyond, successive birthdays. The methodology dates to the seventeenth century and calculates, among other measures, LIFE EXPECTANCY on the basis of how many members of a hypothetical COHORT of 100,000 newly borns survive to reach each of their subsequent birthdays, assuming that the pattern of age specific death rates that prevailed at the moment of birth continues into the future. While the intermediate information on survival rates continues to be of direct interest to those calculating insurance and pension premiums, the related method of survival analysis has emerged as an important tool in longitudinal studies of migration, marriage and poverty (Plane and Rogerson, 1994). AJB Bailey, Blake and Cooke, 2004). While stages in the life course are associated with biological age, these associations vary across time and place, given widespread differences in life expectancy and chances depending on political economic conditions.

life world  Synonymous with the TAKEN-FOR-GRAANTED WORLD, the everyday lifeworld of habitual actions and attitudes is the foundational setting of Schutzman’s PHENOMENOLOGY and the closely related SYMBOLIC INTERACTIONISM of G.H. Mead. Introduced to geographers in the HUMANISTIC GEOGRAPHY of Anne Buttimer (1976) and others, lifeworld comprised the relational and meaningful places of direct experience where intentional actions unfolded and identity was assembled. Lifeworld is socio-centric and corporeal in its range and clarity. However, it is not static but, as Buttimer stressed, dynamic, concerned with movement and rhythm that integrates parts into an experienced whole, with routines that sediment a way of life in a geographic setting (Mels, 2004). Such a fusion of intersubjective meaning and physical location is inherent to the geographies of HOME, COMMUNITY and NATION. The lifeworld is a basic building block in attempts to construct a meta-social theory by Berger and Luckmann, Giddens and others. In his influential formulation, Jürgen Habermas counters the practical intersubjective interests of the lifeworld, retrieved through HERMENEUTIC study, with the instrumentality of political and economic systems accounted for through positivist methods (see CRITICAL THEORY).

limits to growth  The proposition, central to much modern ENVIRONMENTALISM, that the finiteness of biophysical resources places absolute limits on demographic and economic growth. Although the idea is important in classical political economy, the phrase entered widespread modern circulation only in 1972, when it appeared as the title of a report by a group known as the Club of Rome (Meadows, Meadows, Randers and Brehens, 1972). Based on early exercises in computer modeling, the report argued that humanity was on
the brink of exceeding the Earth’s CARRYING 
cAPACITY and precipitating widespread social 
and ecological CRISIS. Although the report 
looked at resources in addition to those di-
rectly related to agricultural production, its 
argument was essentially a Malthusian one 
(see MALTHUSIAN MODEL). It was an impor-
tant milestone in the development of neo-Malthusian 
trends in modern environmentalism, such as a 
concern with the ‘population bomb’, as well as 
an impetus towards calls for a ‘steady-state 
economy’ and the development of the field of 
ENVIRONMENTAL ECONOMICS.

Belief in absolute limits to economic growth 
based on material scarcity, and the politics 
that follow from such a position, constituted 
a direct challenge to the Promethean views of 
human activity arguably shared by neo-clas-
cical economics and classical Marxism, both of 
which denied the necessity of such absolute 
material limits to human productivity. In 
geography, David Harvey (1974a) and others 
strongly criticized resurgent neo-Malthusian 
models for overlooking issues of distribution, 
justice, scale, changes in technology and prod-
uctivity, and other factors that would compli-
cate or undermine their predictions. A 
significant amount of geographical work over 
the subsequent several decades has essentially 
reproduced and elaborated this debate in vari-
oius arenas. Perhaps the most notable example 
is the rapid growth of scholarship centred on 
the concept of ENVIRONMENTAL SECURITY. This 
literature is constituted largely by debates be-
 tween dominant neo-Malthusian views, which 
continue to articulate theories of how demo-
 graphically fuelled conflicts over increasingly 
scarce natural resources will produce escalat-
ing violence and geopolitical instability (see 
RESOURCES WARS), and more critical voices, 
which continue to insist on attention to the 
social causes, contexts, and complexities of 
such scenarios (see Dalby, 2004).

Other work in geography, though, has revis-
ited the question of natural limits with increas-
ing theoretical nuance, moving beyond the 
simple rejection of it in much of the Marxist 
tradition. Theorists of natural resource indus-
tries in particular have begun to take nature’s 
materiality seriously by attempting to under-
stand not only the constraints, but also the 
affordances and surprises, that biophysical sys-
tems present to human activities in specific 
circumstances, developing concepts such as 
appropriationism, substitutionism, eco-regu-
lation, hybridity, and the formal versus the 
real subsumption of nature to capital (see 
Boyd, Prudham and Schurman, 2001). Nat-

ural ‘limits’ are thus increasingly understood 
and investigated as differentially malleable 
conditions of possibility for particular forms 
of human activity, rather than as absolute 
and universal barriers. Such a perspective has 
proved compatible with recognition of the ne-
cessarily political and social character of any 
claims about natural limits, as emphasized in 
the literature on social constructionism. JM

linear programming A type of OPTIMIZATION 
MODEL used to find the optimal solution to a 
wide variety of economic, business and geo-
graphical problems, such as the minimum total 
transport cost of shipping goods through a geo-
graphical network. Optimization models have an 
objective function (the quantity to be minimized 
or maximized) and a set of constraints that define 
the possibilities and requirements (limits on sup-
ply, demand requirements, route character-
istics). In linear programming both the 
objective function and the constraints are linear 
functions and this makes solution fast and easy, 
even for very large problems. The TRANSPORTA-
TION PROBLEM is a special form that has many 
geographical applications. LWH

linkages The contacts and flows of informa-
tion and/or materials between two or more 
individuals. The term is widely used in both 
INDUSTRIAL GEOGRAPHY and the geography of 
services to indicate inter-firm interdepend-
ence and its effects on location choice (see 
AGGLOMERATION). A firm’s linkages can be 
divided into: (1) backward, which provide 
goods and services for its production activities; 
(2) forward, links with customers purchasing 
its products; and (3) sideways, interactions 
with other firms involved in the same pro-
cesses. Membership of such networks in 
increasingly seen as crucial to success and 
survival for a firm, especially a small firm. 
(See also INTEGRATION). RJ

literature Although the meanings of this 
term have varied widely, two have been of 
special interest to geographers: (a) imaginative 
writing, especially that deemed to be of espe-
cially high quality or status by a critical estab-
lishment; and (b) published scholarly work on 
a particular topic.
Literature in the sense of imaginative writing has attracted the analytical attention of cultural geographers over the past 30 years in particular. Novels, stories, poems and travel narratives have been studied for their representations of places, landscapes and nature, of regions and nations, and of geographical processes such as urbanization, migration and colonization. An interest in literature was evident in some of Alexander von Humboldt’s writings, and received scattered attention at moments through the early and mid-twentieth century. Darby’s essay on the regional geography of Hardy’s Wessex (1948) was an early outlier, but it extracted the descriptions of landscape from the novels and used them to reconstruct the regional geographies of Dorset in the first half of the nineteenth century: as Darby had it, placing “the pictures that Hardy drew” in “the sequence that stretches from John Coker’s survey in the seventeenth century up to modern accounts of the land utilization of Dorset” (p. 343). Darby displayed no interest in exploring the significance of these places for the characters and events in the novels, still less in approaching these “geographies” with the sensibility of a literary scholar (cf. Barrell, 1982). Hardy’s texts were read as more or less inert sources, and Darby had no interest in (or awareness of) how, as Brousseau (1995, p. 89) later put it more generally, a novel “has a particular way of writing its own geography.”

It was not until thirty years after Darby’s essay that literature received any sustained and systematic attention in HUMAN GEOGRAPHY, as part of the growing attention to environmental perception, imagery, attitudes and values, and to consciousness as an aspect of culture. This was the product of the critique of SPATIAL SCIENCE and the flowering of a HUMANISTIC GEOGRAPHY that renewed the discipline’s traditional connections with the HUMANITIES in different, more analytical, registers, and which had a particular impact on CULTURAL GEOGRAPHY (Salter and Lloyd, 1977; Pocock, 1981). These explorations intensified through the closing decades of the twentieth century and into the opening decades of the twenty-first. This was achieved, in part, through a much closer and usually theoretically informed engagement with the work of literary scholars and cultural critics – from Walter Benjamin and Mikhail Bakhtin through Edward Said and Raymond Williams to Terry Eagleton and Fredric Jameson – many of whom had an interest in SPATIALITY and the cultures of COLONIALISM, CAPITALISM and MODERNITY that was at once close to and consequential for human geography more generally. Their critical writings had a considerable impact on explorations of MODERNISM and POSTMODERNISM in the cities of the global North, of IMAGINATIVE GEOGRAPHIES produced under the signs of ORIENTALISM, TROPICALITY and similar projects, and on theorizations of POWER and CULTURE. These endeavours were reinforced through a second source of interest in literary matters: human geography’s engagement with styles of contemporary PHILOSOPHY that Rorty once described as forms of cultural criticism: these included his own version of PRAGMATISM but also POST-STRUCTURALISM (the literary sensibilities of Foucault and Derrida are especially salient, though Eagleton has railed against Spivak’s).

The turn to literature has raised an interesting question in a field dominated by the discourses of social science: Exactly what kind of evidence is literature? For some human geographers, it is both indicative of the capacity of human beings to make meaning and an expression of a specific meaning-filled culture (e.g. Bunkse, 2004); for others, and not mutually exclusive of other meanings, it is at once a reflection of political–economic realities and a way of thinking them through (e.g. Henderson, 1999); for others, it is part and parcel of the production of regional identity and memory (e.g. DeLyser, 2005). In human geography, the meaning of ‘imaginative writing’ extends to some degree to narratives of travel and exploration (see TRAVEL WRITING). While not pure figments of imagination, these writings are often structured around certain tropes and narrative conventions that give TEXTUALITY as such a constitutive role in their making: travel narratives do not simply mirror or correspond to the world (e.g. Blunt, 1994). It is probably safe to say that most contemporary geographical study of literature is not so much interested in literature per se than in literature as a species of REPRESENTATION, DISCOURSE and TEXT, interest in which has grown with the CULTURAL TURN in the social sciences (Barnes and Duncan, 1991). It is not entirely a one-way street, and the traffic has been marked by both interesting departures and juddering collisions: literary scholars would have no difficulty in recognizing the force and originality of Kearns’ (2006b) reading of the spatial dialectics of James Joyce, for example, and the three spatial motifs he identifies (circulation, labyrinth and palimpsest) thread out on to the wider terrain of British colonialism and Irish nationalism; but most
human geographers would be bemused at the
traces of spatial science to be discerned in
Moretti’s (1998, 2005) spatialized apprehen-
sions of the European novel and literary
history.

Literature as a social and geographical phe-
nomenon, involving the geographical spread
of avowedly ‘literary’ forms (e.g. the novel),
the emergence of publication and printing
centres, literary celebrity and certain ideo-
logical effects, has been studied extensively.
Few such studies have been undertaken by
geographers, but the classic account of ‘the
coming of the book’ in Europe devoted a cen-
tral chapter to ‘the geography of the book’
(Febvre and Martin, 1984 [1958], pp. 167–
215), and historians and historical geograph-
ers followed in their footsteps to study the
DIFFUSION of printing, the spread of literacy,
the spatial impress of censorship and other
topics. These historical treatments underscore
that both the forms and meanings of literature
have changed dramatically. Literature’s mean-
ing as a form of imaginative writing endorsed
by a critical establishment came about over
time (see Williams, 1977; Eagleton, 1983).
Its early meaning (into the eighteenth century)
was closer to the idea of literacy; that is, it was
the property or characteristic of learned, read-
ing elites. Literature’s meaning as a mark of
distinction regarding what one could do (read)
was then extended to what one read (books).
The question of what kinds of books counted
as literature then followed (Williams, 1977).
There was (and there remains) no easy distinc-
tion between fiction and fact as the way to
demarcate literature from other sorts of writ-
ing – witness the example of travel writing.
The difference between works of, say, philos-
ophy, history and politics as opposed to fic-
tional writing was codified in response to
industrial capitalism, which was seen as sup-
pressing creativity. This is not to say that lit-
erature, or more specifically what cultural
elites claimed counted as literature, escaped
an ideological function within industrial capi-
talism (Eagleton, 1983). Literature as creative
output was also caught up with the notion of a
‘national’ literature and the establishment
(and struggle over) nation-state based literary
canons. The formation of the literary canon
continued with it a new meaning: literature
exemplified for national critical establishments
the best of what a nation-state could achieve
and served the purposes of unifying national
identity (see also NATION; NATIONALISM). (The
logic of specifically regional literatures and
regional literary canon formations runs in
parallel. But contrast these impulses towards
national and regional narratives of literary
formation with the recent identification of a
‘global literary space’ à la world systems
theory: see Casanova, 2005.)

Yet the meanings of literature have in fact
remained multiple, or perhaps become mul-
tiple once again, albeit in different ways.
Most of what human geographers have had
to say about ‘literature’ has focused on the
book, specifically the novel or the travel nar-
rative, and yet many of the scholars on whose
work they draw have also had important things
to say about other cultural media: ART, drama,
FILM, MUSIC, photography and video. Human
geographers have explored these too, but they
have displayed much less interest in literary
dramatic works (other than their staging: see
Chamberlain, 2001; Pratt and Johns, 2007)
except, by analogical extension, in ideas of
PERFORMANCE. This is surprising since, as
the image of Shakespeare’s Globe Theatre
reminds us, drama has long had important
things to show us about the production of

Printed work of many kinds continues to be
referred to as literature, whether this is the ‘lit-
erature’ produced by political campaigns, ad-
vertising literature, best-selling novels or, still,
literature-capital. Within the academy, ‘litera-
ture’ also means the collective, published schol-
arily work pertaining to some field (‘the
geographical literature’), which typically has
its own (contested) canon and its own (conten-
tious) critical establishment. Literature as spe-
cifically scholarly work is not simply a product
found on the bookshelf or downloadable as a
PDF. It is a process that involves discernment,
vetting, peer review, editorial negotiation and
not a little politics. The scholarly literature is
thus not a thing: it is a social relation out of
which are wrought scholarly debate or consen-
sus, cases for tenure (or not), new journals or
lapsed subscriptions, expectations among re-
searchers and between teachers and students,
and struggles won or lost over the lingua franca
of scholarship as such.

A much less explored resonance between
geography and literature is the idea that
scholarly geography can be literature in the
creative sense of the word (cf. Bunkse,
2004), though today’s human geography is
no stranger to experiments with literary form,
as in the work of Marcus Doel, Gunnar
Olsson or Allan Pred, for example, and there
are many other human geographers who
write with an ear to cadence and an eye to
image. But even ‘geographical literature’ in
its radically non-experimental, more technical sense can be subject to the same disciplined processes of critical reading that literary scholars apply to poems and novels, and in as many ways. The process of theoretical critique in human geography is not only about the collision of contending concepts, therefore, but is also about its text-ures, the very languages and grammars of geographical enquiry: it can and should include the analysis of METAPHOR and RHETORIC, a disclosure of the MASCLINISM and PHALLOCENTRISM of the formal structure of an argument or the DECONSTRUCTION of geographical texts. This ought to come as no surprise: the root meaning of ‘Geo-graphy’, after all, is ‘Earth-writing’.

**local knowledge** A term coined by the English philosopher Gilbert Ryle, and popularized by the American anthropologist Clifford Geertz (1983). Local knowledge refers to the double idea (1) that all knowledge is geographically and historically bounded, and (2) that the local conditions of its manufacture affect the nature of the knowledge produced. Note that local knowledge refers to the context in which knowledge is produced, not the geographical domain to which knowledge applies. The physicist’s string theory, for example, is a piece of local knowledge even though its explanatory province is infinitely large, even beyond the known universe. To take in turn the two parts of the definition:

(1) Knowledge is historically constrained, and produced within particular material settings that include geographical site, particular kinds of human bodies, and specific types of buildings, machines and equipment. The key word is produced. Producing knowledge contrasts with the conventional view that knowledge is acquired through discovery (dis-cover, literally to uncover). In the discovery view, knowledge is assumed to be free floating and pre-existent, requiring only the right conditions to be revealed. For knowledge to be produced, however, suggests something different; that there is an active process of creative construction ‘on site’ according to specific local rules and conditions. An example is graduate students making vigorous use of large desk calculators in the statistics laboratory at the University of Iowa in the late 1950s, and in the process producing geography’s QUANTITATIVE REVOLUTION (Barnes, 2004b).

(2) The material and historical setting, and associated social interests, enter into the very lineaments of knowledge. Knowledge does not come from the sky, from heavenly inspiration, but from engaging in particular kinds of social practices that are historically and geographically grounded (see SITUATED KNOWLEDGE). Knowledge is irreducibly social, never innocent, always coloured by the context of its production. This does not mean that it is singularly determined by its context. Multiple responses to any situation are possible, though their range will be constrained by the places and predicaments that have in various ways, sometimes unremarked and unconscious, both summoned and shaped them. Examples are legion: ENVIRONMENTAL DETERMINISM expressed (and helped to legitimize) the racist and imperialist impulses of late-nineteenth-century Europe; REGIONAL SCIENCE represented the INSTRUMENTALIST, MASCLINIST and economistic sentiments of much of mid-twentieth-century America; and POSTMODERNISM reflected a late-twentieth-century consumer capitalism constituted by flickering images and fabricated identities. In each of these cases, the knowledge that emerged is shaped by the particular, non-repeatable constellation of forces, causes and determinations found at a given time and place. One can begin to trace their effects, and they clearly travel and will be found in other times and places too, but not in the exact same combination with the same consequence. Each local context will be different, producing different knowledge. The important corollary is that universal claims to truth are unsupportable. Knowledge is always made inside the bubble of local context, with no means of moving outside for ‘a god’s eye view’ (Haraway, 1991c, p. 193).

The issue of local knowledge has been central recently in at least two disciplines. First, in anthropology, Clifford Geertz (1988, p. 137) argues for the impossibility of ‘telling it like it is’, because ethnographic accounts are as much about the world of the ethnographer as the world that is represented (and transparently obvious in early ethnographies; Geertz,
1988: see also ethnography). A recent complication is the effect of an increasingly fluid, mobile and hyperactive world, which seemingly undermines the idea of fixed local knowledge. The problem is that while knowledge is produced at local sites, it increasingly travels. The response has been to examine networks of knowledge, conceived as inter-local interactions. Local knowledge travels, but it never achieves universality.

Second, in the field of history and philosophy of science, ‘telling it like it is’ is also not an option, since Kuhn (1970 [1962]) devised his concept of a paradigm. Science is conceived as being shot full of social interests, reflecting the time and place of its manufacture: it is local knowledge. Initially the Edinburgh School, and feminists such as Haraway (1989), provided detailed, historical studies, laying bare the local social interests at play. Other work—for example, Latour and Woolgar (1979)—concentrated on specific local sites, such as the laboratory, and concomitant micro-practices of research and relations of power that produce knowledge. The point, as Rouse (1987, p. 72) writes, is that scientists ‘go from one local knowledge to another rather than from universal theories to their particular instantiations’.

In spite of geography’s historical concern with the local, the discipline’s recent past has been dominated by a quest for universal knowledge. After the Second World War much of geography, or at any rate those areas colonized by spatial science, was bound up with the search for grand theory and its universals, predicated on essentialism and foundationalism. Things have changed since the 1990s with the advent of postmodernism and post-structuralism. Although the term ‘local knowledge’ is rarely used as such, the sentiments that it expresses are now found in recent works on disciplinary history (Livingstone, 2003c: see geography, history of), around biophysical process in nature (Castree, 2005a) and economic geography (Gibson-Graham, 2006b [1996]).

Rouse (1987, ch. 4).

local state The set of institutions of the state that have sub-national territorial remits. The local state includes elected local government as well as local agencies of public administration and public service provision and local regulatory and judicial authorities. However, it does not include all the actors involved in local governance, some of which are drawn from the private and voluntary sectors.

The concept of the local state came to prominence with the publication of Cockburn’s The local state: management of cities and people (1977). Cockburn argued that the local state should be understood as an integral part of the capitalist state as a whole, and that it operates to sustain the social relations of capitalism at the local level through its management of social reproduction. Rejecting this approach, Saunders (1979) proposed a ‘dual state’ thesis that theorized the state in terms of two distinct roles: the promotion of production (the sphere of the central state) and the maintenance of consumption (the sphere of the local state). In this view, the local state is concerned particularly with providing the means of collective consumption, such as housing and local public services. These two positions were representative of a more general debate about the degree of autonomy of the local state. Is the local state merely an arm of the central state operating at the local level, or does it have at least some effective independence? All large nation-states find that some system of local administration is a practical necessity to cope with the complexities of managing extensive territories. However the autonomy of local state actors varies considerably according to the legal, constitutional and fiscal framework within which local institutions operate and the extent to which they can be ‘captured’ by political parties or interest groups opposed to central government policies.

The concept of the local state was particularly important in geographical research during the 1980s (e.g. Clark and Dear, 1984; Duncan and Goodwin, 1988). This was in part a reflection of the conflict-ridden nature of central–local relations during the political ascendancy of the New Right. Since then, a number of factors have contributed to a decline in the use of the concept. First, the hegemony of neo-liberal models of social and economic development in many countries has curtailed the scope for the local state to pursue alternative political strategies. Second, the recognition that non-state actors play important roles in shaping local areas has contributed to a shift in research focus away from theories of the state and towards theories of governance. Third, extensive research on the re-scaling of the state has drawn attention to the relational nature of scale, and challenged the notion that particular kinds of institutions or practices necessarily operate at particular spatial scales. Fourth, the idea that ‘the’ local state exists as a unified or coherent entity has
been undermined by new theoretical perspectives including post-Marxism and various forms of post-structuralism.

**local statistics** A local statistic is often a numerical value describing some aspect of a locality or its population (e.g. the percentage unemployed) and offering greater detail than more aggregate regional or national statistics. The meaning is similar in spatial statistics, where local statistics are values obtained for geographical subsections of a larger study region, often compared to each other or to an average. Here they contrast with global methods, including regression analyses fitted for the entire region, that risk missing statistically significant and geographically localized variations in the relationships between variables. Local statistical methods include point pattern analysis, geographically weighted regression and local indicators of spatial association (Anselin, 1995).

Fotheringham, Brunsdon and Charlton (2000).

**locale** A setting or context for social interaction, typically involving co-present actors. In structuration theory (Giddens, 1979, 1984), locales provide the resources on which actors draw. Different kinds of collectivities are associated with characteristic locales (Giddens, 1981, p. 39): the locale of the school is the classroom; that of the army, the barracks; and so on. Despite his emphasis on co-presence, Giddens (1984, p. 118) also suggests that locales may range ‘from a room in a house . . . to the territorially demarcated areas occupied by nation states’: as Thrift (1983) emphasizes, ‘a locale does not have to be local’.

**Suggested reading**
Thrift (1983).

**local–global relations** A concept that seeks to capture the dialectical nature (see dialectics) of the connections between global processes and local forces. The term ‘local–global’ resonates differently for different scholars, resulting in a number of different approaches to the intersections of local and global forces. Some scholars have pursued empirical cases in which they identify strong global forces – especially those of modernity and the market – that impact and alter local places and customs. An example of this type of scholarship can be found in Allan Pred’s (1990) work on late-nineteenth-century Stockholm, where the rapid growth of capitalist production processes greatly affected the language and symbolic codes of the city residents (see also Pred and Watts, 1992).

A second type of research investigates the ways in which local places and cultures incorporate and/or transform global processes. Particularly prevalent in the work of cultural anthropologists, this body of scholarship eschews meta-narratives of global capitalism and emphasizes instead the power of diverse local traditions in altering the meanings and workings of global processes. A good example is Watson’s (1997) edited volume investigating the localization of American corporate and culinary culture (via ethnographies of McDonald’s) in numerous cities of East Asia.

A third body of research attempts to combine and transcend these earlier formulations by arguing for a process of globalization, foregrounding the ways in which the local and the global are completely interwoven and impossible to pull apart. Economic geographers who seek to emphasize the inter-textual, multi-layered nature of scale have employed this concept (Swyngedouw, 1997; Brenner, 2003). It has also been used frequently by those interested in the changing nature of citizenship and the hybrid qualities of identities formulated in conditions of transnationality (Yuval-Davis, 1999).

A number of critiques have been levelled at all three of these employments of the local–global concept. The strongest has emerged from the feminist literature, which has interrogated the binary nature of the paired words as well as the often uncritical and ungrounded invocations of both the global and the local (see also Freeman, 2001). As Hart (2001, p. 655) notes:

In addition to active/passive and dynamic/static, these [binaries] include economics/culture, general/specific, abstract/concrete and, very importantly, dichotomous understandings of time and space, in which time is accorded active primacy while space appears as a passive container. This conflation of ‘the global’ with dynamic, technological-economic forces restlessly roving the globe defines its inexorable – and inexorably masculine – character. By the same token, ‘the local’ appears as a passive, implicitly feminine recipient of global forces whose only option is to appear as alluring as possible.
Other critiques include the observation that many of the local–global narratives that scholars employ have focused on the moment of impact between global and local processes, and as a result have underplayed the ongoing power dynamics between local–local forces (Ortner, 1995). By the same token, the actual workings and trajectories of perceived global forces such as CAPITALISM are often assumed rather than investigated empirically, leading to a blind spot with respect to global–global dynamics. This latter critique has been taken to the extent of questioning the very nature of capitalism itself (Gibson-Graham, 2006b [1996]). A final, more implicit critique has emerged with the literature on TRANSNATIONALISM, wherein scholars have preferred to privilege the ongoing movements between scales and across BORDERS rather than the perceived static conceptualization of both scales and borders that is suggested by the local–global terminology.

**locality** A place or region of sub-national spatial scale. Locality studies were a prominent feature of British urban and regional research in the 1980s and 1990s. They developed from attempts to understand the process of socio-economic RESTRUCTURING and the role of place and spatial variation within it. Locality was a key organizing concept for three research programmes funded by the UK’s Economic and Social Research Council in the 1980s: the ‘Changing Urban and Regional System’ initiative (CURS), the ‘Social Change and Economic Life’ initiative (SCELI) and the ‘Economic Restructuring, Social Change and the Locality’ programme. At the centre of each was a series of studies of the impact of restructuring on particular places or regions. A key concern of these ‘locality studies’ was to collect detailed empirical evidence to assist the identification of the nature, causes and consequences of spatial differentiation in processes of change (Cooke, 1989).

The research raised a series of methodological and theoretical issues that became bound up with wider and sometimes acrimonious debates. These included: the delimitation of localities for research; the relationship between locality studies and critical REALISM; the extent to which localities should be seen as ‘pro-active’ agents of their own transformation; the politics of the ‘empirical turn’; the question of whether a concern with local difference risked limiting the scope for generalization and theoretical development (Smith, 1987); and the gendered implications (see GENDER) of most locality studies’ focus on the sphere of waged labour and their limited treatment of cultural relations.

Since the end of the formal research programmes, the concept of locality has been much less prominent in the geographical literature, but two more recent developments during the 1990s may be noted. First, there has been a much stronger emphasis on relational and networked concepts of locality and on the links between localities and other spatial scales. Murdoch and Marsden (1995) draw on ACTOR-NETWORK THEORY to suggest that ‘localities should be seen as constituted by various networks operating a different scales’ (p. 368), while Amin (2004b) has proposed a wholly non-territorial view of places as ‘unbound’.

Second, many of the issues highlighted by the localities debate have been translated into new conceptual frameworks. For example, the upsurge of interest in GLOBALIZATION during the 1990s has involved a recasting of the issue of local specificity in terms of global–local relations, while the further development of CULTURAL GEOGRAPHY has seen increasingly sophisticated treatments of the relationships between politics, place and IDENTITY.

Suggested reading

**localization** A term often contrasted with GLOBALIZATION and meant to capture the importance of PLACE-based activities. Localization refers to the necessary embeddedness of economic processes, which always reflect their social, political and geographical context. All activities require some degree of spatial fixity and many obtain significant advantages from being geographically localized. These advantages include economies of AGGLOMERATION as well as more sociocultural advantages pertaining to face-to-face contact, the formation of personal NETWORKS, and the creation of centres of innovation and knowledge (Amin and Thrift, 1994a).

**location quotient** A quantitative measure used to describe the concentration of a group or an activity in a locality or region relative to that of a larger area such as the countrywide or national norm. The quotient is the ratio of the
LOCATION THEORY

local concentration to the national figure, and location quotients have been widely used to measure regional employment specialization. For example, if locality A has 53.2 per cent of its employed population working in manufacturing and the national percentage is 28.6, then the quotient for region A is 53.2/28.6 = 1.86. A quotient greater than 1.0 indicates greater concentration in the region than the national norm, and a value less than 1.0 indicates relative absence. Location quotients provide a simple way of making ECONOMIC BASE THEORY operational.

**location theory** A historically and intellectually varied body of THEORY and techniques concerned with the EXPLANATION and sometimes PREDICTION of the location of individual and aggregate economic activities. Until around 1980 location theory was a distinct canon, with a well-defined history, core issues and methods, and a roll-call of alumnae. No more. Location theory is less shapely, more voluminous, spilling out of its earlier constraints, but more interesting as a result.

Scott (1976a, p. 106) claims that the first location theorist was Sir James Steuart (1712–80), a Scottish political economist. Most other histories, however, start with the German location school, whose first member was Johann Heinrich von Thünen (1783–1850) (Blaug, 1979; Ponsard, 1983). A Prussian landowner, agriculturalist, political reformer and embryonic neo-classical economist (Alfred Marshall said, ‘I loved von Thünen above all my masters’; quoted in Blaug, 1990, p. 23), von Thünen crafted an abstract location MODEL using a method he called ‘*Form der Anschaung*. Deploying calculus and capacious observations made from his country estate, he developed a theory of concentric agricultural land use based on the variation of land RENT by location (see VON THÜNEN MODEL).

Alfred Weber (1869–1958), brother of sociologist Max, was a second member of the German school (‘the true heir of von Thünen’; Blaug, 1979, p. 28). Although much of his work concerned cultural history, he also experimented with a method of establishing the most profitable location for a factory in his quest to understand the origins of AGGLOMERATION in an early twentieth-century Germany racked by a pervasive sense of crisis in its great cities. His discussion isolated the relative geographical pull of FACTORS OF PRODUCTION conceived initially on a triangular grid, and he used both a physical model (the Varignon frame) as well as complex mathematics (so complex that he needed help from Georg Pick, the mathematician who assisted Einstein in formulating relativity) to derive a solution for optimal location (minimizing costs, maximizing revenue).

August Lösch (1906–45) and Walter Christaller (1893–1969) round out the school. Christaller, who was trained as a geographer, developed CENTRAL PLACE THEORY in the 1930s both to explain the location of different kinds of services and also to undertake regional planning. Its geometries assumed a truly grotesque form when Christaller was employed by the Third Reich’s Planning and Soil Office in 1940: he proposed to deploy the theory to reconfigure the geography of Poland following its depopulation by relocation, deportation and extermination (see HOLOCAUST). Lösch, an economist trained at Bonn University, independently developed his version of central place theory during the same period, but unlike Christaller couched it in mathematical terms as spatial equilibrium, with services, industry and consumers arranged within a hexagonal net of market areas. Like Christaller, there was a NORMATIVE impulse to his project, but Lösch despised Hitler (as did Alfred Weber), and died from deprivations he suffered in maintaining his values against those of the Nazis (see FASCISM).

The contributions of the German location school were rigorous, conceptually pointed and abstract. Theirs was a world apart from the a-theoretical approach that dominated ECONOMIC GEOGRAPHY until the mid-1950s, in which location was ‘explained’ by merely inventorying a set of *ad hoc*, unique geographical factors. Isard (1979, p. 9) recalls that economic geographers at that time had ‘little concern for analysis’ and that they made ‘no attempt’ even ‘to fuse ... location[al] factors into a simple cost calculus’. Isard’s own REGIONAL SCIENCE movement, which for a period was symbiotically linked with economic geography, helped from the outside to push the sub-discipline into the mould of the German locational school – and which Isard (1956) was also concerned to extend. A similar move to reshape the field came from inside the discipline, with the attempt to establish human geography as SPATIAL SCIENCE during the QUANTITATIVE REVOLUTION of the late 1950s. Work at two of the earliest sites of that revolution was explicitly directed towards creating a location theory that was systematic, general and empirically exact: McCarty, Hook and Knox (1956) at Iowa drew on CORRELATION and REGRESSION techniques to explain regional industrial location, while Garrison, Berry, Marble, Nystuen...
and Morrill (1959), including several of his soon-to-be-famous graduate students (the "space cadets"), combined German location theory with demanding statistical analysis in their studies of highway development in Washington State.
