Haggett's influential (1965) book, *Locational analysis in human geography*, summarized and solidified the new approach to location theory (see also *Locational Analysis*). It was to be formal, empirically rigorous, and undergirded primarily by *neo-classical economics* (both indirectly via the German school and regional science and directly from mainstream economics). A central topic was the firm, a staple of *neo-classical micro-economic analysis* and underpinned by assumptions of *rational choice theory* and perfect competition (many small producers, none of which control price). The theory of the firm was translated directly into spatial terms by Isard, and later in economic geography by Smith (1981a [1971]). But chinks in the armour of classic location theory were soon revealed. First, the determinacy of rational choice was shown to be unrealistic, and ideas of 'bounded rationality', or 'satisficing behaviour' were preferred, producing a literature on the *behavioural geography* of firm location (Pred, 1967, 1969). Second, perfect competition was demonstrably imperfect for understanding the contemporary world of *transnational corporations*, leading to an alternative literature on the 'geography of enterprise' (later 'corporate geography') focused on firms as institutions, decision-making hierarchies and branch plant economies (McNee, 1960; Hayter and Watts, 1983).

The disquiet only got worse. David Harvey, who earlier in his career had drawn on classical and neo-classical models of agricultural location, including von Thünen's work, and explored general models of the evolution of spatial patterns, turned to *Marxism*, and particularly Marx's own writings, in the early 1970s and pursued a radically different approach. His subsequent analysis of the historical geography of *capitalism*, brilliantly realized in *The limits to capital* (Harvey, 1999 [1982]), did not so much ignore the questions of traditional location theory as pose them in another register altogether. His emphasis was less on accounting for the locations of economic activities than in disclosing the connections between the crisis-ridden dynamics of capitalism and its *uneven development* as a *space-economy*. Doreen Massey's work around the same time was indebted to Marxism too, but it had a much more direct impact on location theory. Like Harvey, she was trained in the orthodox approach, even studying briefly with Isard. Her formulation began in the early 1970s with a detailed internal critique of orthodoxy arguing that applying *neo-classical economic theory* to location generates fundamental and irreparable logical contradictions. The alternative that she constructed over the next decade or so combined the theoretical postulates of *political economy* with the philosophical armature of *realism*, culminating in her watershed book, *Spatial divisions of labour* (Massey, 1984). This was crucially important because it demonstrated that location theory need be neither formal nor *neo-classical*, and because it considerably expanded both what could count as factors bearing on location (in her case, *class* and *gender*, politics and culture) and what could constitute theoretical explanation (in her case, a 'geological metaphor', taking the form of *layers of investment*; Barnes, 2001).

Massey's larger point was that the object of location theory – sites of economic activity – could not be separated from the wider, geographically variegated social setting of capitalism. Her argument was starkly reinforced by the setting of her own study: the massive *deindustrialization* of the UK during the late 1970s and early 1980s (see also *division of labour; locality studies*).

A similarly inspired argument emerged shortly afterwards among a group of economic geographers in California, although their context was utterly different: the study of vibrant capitalist production associated particularly with high-tech and high-end economic activities. Scott (1988b) developed what he called 'neo-Weberian' location theory drawing eclectically on the work of neo-Marxist economist Piero Sraffa (see *neo-Ricardian economics*) and that of institutional economists Ronald Coase and Oliver Williamson (see *institutional economics*). Storper and Walker (1989) elaborated an 'inconstant geography of capitalism' roiled by technological change and social conflict. They stressed the tightly interlinked – 'network' – character of activities in which social and economic institutions cross-cut and interleaved within specific regional formations. The consequence was a rediscovery of the idea of *industrial districts*, first recognized by Alfred Marshall at the turn of the twentieth century: dense geographical nodes of tightly knit complementary manufacturing
activities, sustained by strong formal and informal social connections – which Storper (1997b) labelled ‘untraded interdependencies’. During the 1980s and early 1990s, ‘industrial districts’ seemed to be the answer to every (important) location-theoretical question. Industrial districts were variously linked to POST-FORDISM (and often presumed as its characteristic locational form); to high-tech industries and the INFORMATION ECONOMY (the stress on social connections seemed uncannily made for their study: see Saxenian, 1994); and to an emerging institutional and ‘CULTURAL TURN’ within economic geography itself.

But the shortcoming of the concept of industrial districts, as with Massey’s geological metaphor, was its confinement to the local rather than its ability to address a SCALE increasingly on the lips of economic geographers (and everyone else’s as well): the global (see GLOBALIZATION). One solution was to argue that the global was nothing more than an interlinked set of industrial districts – Scott’s (1998) answer, and at one time, Amin and Thrift’s (1992) too. Another was to continue with the network idea but to expand it to the whole world. Location theory’s charge was to represent and explain network relations – that is, social and economic institutional linkages – wherever they were found across the globe. This approach, also called ‘the relational turn’, drew upon ACTOR-NETWORK THEORY and was not only concerned with social and economic relations, but with material ones too through the incorporation of COMMODITY CHAIN analysis (for examples, see Dicken, Kelly, Olds and Yeung, 2000; Dicken, 2003; Hughes and Reimer, 2004; Yeung, 2004).

Location theory, as its long history makes clear, is no autonomous creation, propelled by its own logic. The logic is only that of its human creators, reflecting their own changing circumstances: from life on an isolated farm to life in an interconnected GLOBE. The vitality of location theory is a consequence of economic geographers keeping abreast of the restless world that they inhabit.

locational analysis A term best associated with Peter Haggett’s (1965) seminal book, Locational analysis in human geography, referring to the logically and empirically rigorous investigation of the spatial arrangements of phenomena and related flow patterns. The heyday of locational analysis in GEOGRAPHY was the 1960s and early 1970s, when vigorous attempts were made to recast the discipline as SPATIAL SCIENCE, but its roots can be traced back to the first half of the nineteenth century and the formation of a German school of LOCATION THEORY. Although locational analysis is now out of fashion in contemporary geography, it has recently been reactivated in economics and advertised as a component of a NEW ECONOMIC GEOGRAPHY.

Haggett’s (1965, p. 1) scrupulously ordered book was fundamentally about ‘the search for order’, by which he meant locational order or ‘SPATIAL STRUCTURE’, as it might be studied in (and as) HUMAN GEOGRAPHY. He (re)turned to the science par excellence of spatial order, geometry, which he described as a ‘neglected tradition in geography’ (p. 15). Accordingly, he organized his first five substantive chapters in geometric terms (see figure):

- movement – the interaction between points;
- networks – the lines of linkage among points;
- nodes – the convergence of links;
- hierarchies – the differential role played by different nodes;
- surfaces – the spaces among nodes.

For each of the five geometries, he deployed rigorous theory and formal numerical methods to analyse and explain associated location issues: this was locational analysis.

Haggett made it clear, though, that his approach was a continuation of the long-standing, albeit ‘deviant’, intellectual tradition of location theory that historically twinned geometrical reasoning with theoretical and empirical analysis. Its origins lie with the nineteenth-century Prussian landowner cum part-time geographer, Johann Heinrich von Thünen (1783–1850), who combined meticulous empiricism, theoretical innovation and a concentric geometrical sensibility to describe and explain location patterns of agricultural land use (see VON THUNEN MODEL). Later contributors to the project, and their geometries, included Alfred Weber (1869–1958) (industrial location and triangles), and August Lösch (1906–45) and Walter Christaller (1893–1969) (CENTRAL PLACE THEORY and hexagons). Walter Isard (1919– ), writing in 1956, nine years before Haggett, synthesized these contributions within his own account of
locational analysis, which he termed regional science (although it was longer on theory and shorter on geometry than Haggett’s version).

Both Haggett’s and Isard’s accounts of locational analysis enjoyed considerable success within human geography for a period, but their star waned from the 1970s for reasons both internal and external to the discipline (see quantitative revolution). During the 1990s, however, the baton of locational analysis was passed to the economists in the form of a New Economic Geography (Fujita, Krugman and Venables, 1999). Unsurprisingly, it was more theoretical and mathematical, less empirical and geometrical, than in its previous version, but the basic mission was unaltered: to represent and analyse economic geographical distributions, and interactions, at all scales using exact, formal techniques and vocabularies.

The tie that binds locational analysis over its more than 150-year history is a conviction that the secrets of location are to be revealed by a ruthless pursuit of rational enquiry and methods, which takes its most perfect form in the logical structure and techniques of mathematics including geometry. The specifics of the location question vary – from point-to-point interaction to the composition of regional networks and surfaces – but the universal rationalist method is constant, thereby ensuring certainty, progress, and truth (so its protagonists claim). In contrast, Barnes (2003) argues that it is not as clear-cut: as with science more generally, or any other form of knowledge, the historical and geographical circumstances of the locational analysts intrude and inevitably corrupt their supposedly pure rationality (cf. local knowledge). This does not detract from the achievements of locational analysis, but it casts them in a different light. For it requires an understanding of the peculiar historical and geographical context of their production, an emphasis ironically quite different from the one offered by locational analysts themselves.

logical empiricism Sometimes used as a synonym for logical positivism, but more often used to mark the post-Second World War Anglo-American movement in philosophy that built upon and extended it (drawing on earlier strands of positivism and empiricism). Committed to empirical verifiability and logic, the original logical positivists were sceptical of theory, because it was neither facts nor operations of logic. Such scepticism could not be sustained in the face of the massive explosion (sometimes literal) of war and postwar science defined by theoretical construction and empirical testing. Something had to give. In this case, ‘empiricism’ was substituted for the troubling term ‘positivism’ (and the root cause of the scepticism). Those working under the banner of logical empiricism were some of the pre-war logical positivists who had immigrated to the United States and there revised their position, such as...
Rudolf Carnap (1891–1970) and Hans Reichenbach (1891–1953), but there were also American adherents, of whom perhaps the best known was Ernest Nagel (1901–85). David Harvey (1969) drew heavily on Nagel’s logical empiricist justification of the scientific method in presenting his own argument for the importance of EXPLANATION in geography.

logical positivism A particular version of the PHILOSOPHY OF POSITIVISM associated with the work of a group of primarily Austrian scientists and philosophers in the 1920s and 1930s known as the Vienna Circle. The convenor of the discussions at the University of Vienna in 1922 was the physicist Moritz Schlick, who invited figures such as the mathematician Kurt Gödel, philosophers Rudolf Carnap and Herbert Feigl, economist Otto Neurath and physicist Phillip Frank. On the edge of the circle but not strictly members were the philosophers Karl Popper (see CRITICAL RATIONALISM), A.J. Ayer (who later popularized the movement for an English-language audience) and Ludwig Wittgenstein.

Wittgenstein was behind the defining proposal of the group, ‘the verifiability principle’. It asserted that scientifically meaningful propositions are those that (1) can be verified empirically by the five senses; or (2) are true tautologically – that is, their truth arises from the very meaning of the terms in which they are expressed such as in logic or mathematics. Propositions incapable of satisfying the principle, and which included most issues that made up the history of Western philosophy until that point concerning aesthetics, morality and religion, were judged senseless if not nonsense. Carnap declared that the Circle ‘reject[s] all philosophical questions, whether Metaphysics, Ethics or Epistemology’. Meaningful propositions would be found in philosophy only when it modelled itself on the natural sciences, and particularly physics.

An immediate criticism was that the verifiability principle could not itself be verified: it was neither an empirical proposition, nor a logical or mathematical tautology. The Vienna Circle’s criterion of meaning was thus, disturbingly, meaningless. Additionally, Popper argued early on that even those in the Circle’s Pantheon, the physicists, did not engage in empirical verification but only FALSEIFICATION: that is, they sought to disprove, not prove, their theoretical claims. As a result of these objections, as well as the physical dispersal of the group (many were Jewish and left-wing and fled Vienna with the rise of Nazism), logical positivism quickly unravelled. By the 1950s, the movement was dead. Its extreme positions were discarded, and any useful ideas were absorbed within the larger movement of analytic and empiricist philosophy that came to define the post-Second World War Anglo-American field (Reisch, 2005).

In HUMAN GEOGRAPHY, however, Guelke (1978, p. 46) suggests that ‘from Hartshorne to Harvey geographical writing on methodology and philosophy has to a greater or lesser degree shown the influence of logical positivist ideas’. But Hartshorne’s (1939) panegyric tome on regional description as the core of the geographical project makes no reference to logical positivism or, indeed, to a single logical positivist. It was in fact Hartshorne’s methodological arch enemy, Frederick Schaefer (1953), who came under the spell of logical positivism. He was influenced at the University of Iowa in the late 1940s and early 1950s by Gustav Bergmann, one of the Vienna Circle refugees, and became the first geographer to apply formal principles of logical positivism to geography through his work on morphological LAWS that were to take the form: ‘If spatial pattern A, then spatial pattern B.’ Watered-down versions of logical positivism were subsequently proffered by an intellectual disciple of Schaefer, William Bunge (1966), and in the form of a textbook by two former graduate students at the University of Iowa, who took the mandatory Bergmann course (Amedeo and Golledge, 1975). All three contributions were part of the QUANTITATIVE REVOLUTION, the movement towards modelling the study of geography on the natural sciences in general, and physics in particular, as part of the project of SPATIAL SCIENCE. That said, many quantitative revolutionaries were ignorant of logical positivism, and not interested anyway. Harvey’s (1969) prospectus for scientific EXPLANATION in geography bears only traces of logical positivism. Its central preoccupation was the scientific method, not philosophy as such, and certainly not the philosophy of logical positivism: Harvey’s understanding of the scientific method was indebted, rather, to LOGICAL EMPIRICISM. Furthermore, both Harvey and the discipline at large were subsequently to move away from this version of the scientific method, rendering discussions of the usefulness of logical positivism of only historical value.
log-linear modelling  Procedures for analysing data at the nominal level of measurement – that is, when the variables comprised unordered categories (such as a binary division – urban/rural – or a set of political parties – Conservative/Labour/Liberal-Democrat etc.). The goal – as in regression (hence the alternative term logit regression) – is to fit an equation that estimates the values in the cells of a contingency table, where the independent variables are also measured at either the nominal (categorical) or ordinal level only; models can also be fitted if one or more of the independent variables are measured at interval or ratio level. The terms of the model presented in logarithmic form, indicate the deviations from the individual cell values of the contingency table from the grand mean for the entire sample being analysed, and can be interpreted as the odds of getting a particular outcome (e.g. the likelihood that electors in urban areas are more likely to vote for one political party than those in rural areas). (See also CATEGORICAL DATA ANALYSIS).  

logit regression models  These models belong to the family of techniques for CATEGORICAL DATA ANALYSIS. They are used when the response variable is either binary (e.g. a person either moved or stayed) or a proportion (the proportion who have moved). The nature of this response variable, such that it cannot exceed 0 and 1, means that the standard regression model should not be used. Instead, the logit (the logarithm of the odds of moving) is modelled and the random part of the model takes on a binomial form so that the stochastic variation (see STOCHASTIC PROCESS) around the underlying relationship is structured to be least when the values of 0 and 1 are approached. Although the modelling is undertaken on the logits, it is simple to transform these to both probabilities and odds for interpretation. The popularity of this form of the binary response model stems from the ability when the predictor is categorical of giving a relative odds interpretation, generating, for example, the relative odds of a person aged over 35 moving in comparison to someone aged under 35.

The multinomial form of the logit model is used when there are more than two possible outcomes; the conditional form is used when analysing choice alternatives and the predictor variables may include attributes of the choice alternatives (e.g. cost) as well as characteristics of the individuals making the choices (such as income); the multi-level logit (see MULTI-LEVEL MODELLING) assesses the effects of variables measured at different levels (such as individual, household and NEIGHBOURHOOD EFFECTS on an individual moving); and the nested logit model is used when there is a hierarchical structure to the outcomes (with moves broken down into short- and long-distance, for example).

longitudinal data analysis (LDA)  A set of QUANTITATIVE METHODS that involve measures over time. In contrast to time-series analysis, in which there tends to be one entity measured a large number of times (cf. SEQUENCE ANALYSIS), LDA is usually concerned with a large number of entities (e.g. people, places or firms) measured a relatively few times. Data for such analysis come from extensive designs (see EXTENSIVE RESEARCH) such as panel or cohort studies. LDA is increasing in importance because it allows the study of development and change, including: the transition from one state to another (e.g. from single to married to separated); the time spent in a particular state (e.g. the length of unemployment); and the determinants of such duration. LDA is fundamental to adopting a life-course perspective in which people are affected by cumulative stimuli over a long period.

The value of such an approach can be seen by contrasting the data analysis of cross-sections with that of a panel. In the former, because we are measuring different people at each time point, we can only assess net or aggregate change – we can only know, for example, that the percentage of the population below the poverty line has increased from 10 to 12. But with panel data we can assess the volatility of micro-social change as individuals move in and out of poverty, thereby tackling questions about the permanent nature of an UNDERCLASS. Such questions are of particular importance in EVIDENCE-BASED POLICY when we are concerned with either affecting change or removing barriers to change. Cross-sectional analysis can also be misleading about the direction of causality, for without repeated measures over time we cannot distinguish between, say, unemployment causing
illness or illness causing unemployment. Measurements over time usually show strong state dependence in that individuals do not move rapidly and continually between different states, so that current behaviour is influenced by past or previous behaviour. Only LDA is capable of taking account of prior information when examining current situations. Moreover, only longitudinal data can separate age and cohort effects – the life experiences of those aged over sixty years may be quite different between cohorts born before and after 1945. Unlike cross-sectional analysis, which analyses variation between cases, LDA also works within cases between occasions. As such, it is much better able to take account of ‘unobserved heterogeneity’, unexplained variation due to the omission of explanatory variables that are either unmeasured or even un-measurable. LDA will improve control for such heterogeneity and help to provide a measure of the extent of its presence (Davies and Pickles, 1985).

Longitudinal data sets have a number of features that provide a challenge for analysis. Thus if the outcome has not yet occurred the sequence is censored, so that in an analysis of longevity there will be people who are still alive at the end of observation period. Standard statistical models are based on the assumption of independence, but repeated measures over time are likely to be strongly autocorrelated. Missing data are also a particular problem, as the requirement of multiple follow-up often leads to attrition: this is a particularly challenging problem when the drop-out is informative, because it depends on what would have been observed if the person had not dropped out.

Technically, there are three broad sets of approaches to LDA:

- **Repeated measures analysis**, in which data on repeated occasions are seen as being nested within individuals, so that we can examine, for example, the growth of income over time and evaluate the changing gender gap; **multi-level modelling** is increasingly being used for such data, as it does not require the measurement of every individual on all occasions to allow between-individual, within-individual and between-occasion variation to be explicitly modelled.

- **Event history analysis** (duration analysis or hazard modelling) is concerned with the timing of transitions from one state to another, so that it is possible to test how the transition rate of moving from one state (e.g. unemployed) to another (employed) is affected by other variables such as education level: these explanatory variables may be either time invariant (such as gender) and/or time varying. In such analyses, the dependent variable is the duration until event occurrence. Single non-repeatable event analysis (e.g. the transition to death) was developed first and is often called ‘survival analysis’, but it is now possible to analyse repeated events (e.g. multiple spells of unemployment and employment), competing risks (e.g. different reasons for leaving a job such as voluntary choosing another job, redundancy, retirement), multiple states (e.g. transitions between single, marriage and cohabitation states) and multiple processes (e.g. joint modelling of partnership and employment histories).

- **Sequence analysis**, which works holistically to identify characteristic time-based trajectories.

These methods have been extended to model spatial choice (Wrigley, 1990), the duration of point patterns (Pellegrini and Reader, 1996) and spatial processes more generally (Waldorf, 2003).

**Los Angeles School** A loose affiliation of Los Angeles-based geographers and urbanists, connected by their theorizations of the LA region and the implications of its dynamics for all cities. The School is associated with a notion of ‘postmodern urbanism’ and an argument that LA’s complex urban form, new economic clusters and inequality signal the future of urbanism (see postmodernism; modernity). Its members argue that contemporary urbanism can be understood less through the concepts of the Chicago School and more through the fragmentary geography of Southern California (Dear, 2001). The School’s work has been the subject of much criticism and debate continues on the efficacy of framing LA, or any single city, as an exemplar of urbanism (Dear and Dahmann, 2008; Mollenkopf, 2008; Simpson and Kelly, 2008).

Dear (2001).
macrogeography  The search for macro-scale empirical regularities in spatial distributions as a basis for generalizations about spatial structures. The approach was pioneered by a physicist, John Q. Stewart (1894–1972), and developed with William Warnitz (1922–88) in a pioneering project funded by the American Geographical Society (cf. geographical societies). Their lasting contributions to spatial analysis/spatial science were (a) the concept of population potential, a cartographic density surface that generalized point (and point-in-area) distributions and was used as a measure of accessibility, and (b) their research on the gravity model of spatial interaction and the related ‘law of least effort’. (See also fractals.) RJ

malapportionment  An electoral abuse in which districts are either defined or allowed to remain in use with unequal populations/electorates, which thereby favours one party over another in the translation of votes into seats. The most successful malapportionment strategy for a party involves defining relatively small districts in areas where it is likely to win seats, and larger ones elsewhere, thereby enabling it to win more seats with the same total number of votes than opponents who win where seats are on average larger. Malapportionment was deemed unconstitutional by US courts in the 1960s, under the equal treatment (14th) Amendment to the Constitution, and all districts within a state must be redrawn with almost exactly the same population after each decennial census. British legislation also requires Parliamentary constituencies to be of equal size, but variations are allowed and produce malapportionment-like effects in the translation of votes into seats. RJ

Malthusian model  An influential and controversial model of population and resources, proposed by Thomas Malthus (1766–1834). Malthus read mathematics at Cambridge and was then ordained in 1793. He published his Essay on the principle of population in 1798 and soon became a controversial figure. The first edition of the Essay was written as a counter to William Godwin’s Enquiry concerning political justice (1793) and the radical interpretation of the science of politics and the means of social improvement associated with the French Revolution in general and the Marquis de Condorcet in particular. Malthus was far less optimistic than his antagonists, maintaining that misery and vice were the inevitable result of the fundamental law of nature, which was impervious to institutional and legislative change.

Malthus specified two ‘postulata’: that food was necessary for life and that the ‘passion between the sexes’ could be regarded as a constant. He then gave mathematical form to his basic Principle: a maximum potential rate of population growth in the form of the geometric ratio \((1,2,4,8,16 \ldots)\) with an assumed arithmetic growth \((1,2,3,4,5 \ldots)\) in food supply. Malthus recognized that population growth would be curtailed either by a rise in mortality associated with what he saw as ‘positive checks’ (war, disease, starvation) or through a reduction in births through ‘preventative checks’ (adultery, birth control, abortion or infanticide), although he was inclined to regard these as all variants of ‘misery and vice’. This was a deductive model, but it was given empirical substance through Malthus’ interest in the population growth that had been observed in the American population, where large acreages of land were made available to settlers who had few if any subsistence constraints.

Malthus’ pessimism about the prospects for England and the Old World in the first edition was tempered somewhat in the much larger and thoroughly researched second edition, published in 1803, in which he was more optimistic than other political economists such as Smith and Ricardo, and held out the possibility of a better balance between numbers and resources achieved through moral restraint, which he primarily regarded as a restraint on marriage. He was inclined to see certain
European societies as exhibiting nuptiality controls, an observation that has led some to argue for a distinctive form of late and variable marriage age, particularly for women, in western Europe (Hajnal, 1965), and which has been used as a basis for understanding the notion of a nuptiality valve primarily responsible for English demographic growth rates rather than the positive check in the period between the sixteenth and early nineteenth centuries (Wrigley and Schofield, 1989 [1981]).

While the Malthusian model has been viewed as a particularly effective device through which to understand a key period in England’s demographic history, it has also received much criticism. It is thought to have failed as predictor of the future, at least in its more pessimistic form, since population growth was sustained at a high rate through much of the nineteenth century, and living standards rose and fertility fell as populations resorted increasingly to marital fertility control, and at the same time infant and child mortality fell dramatically, principally as a result of eradication of infectious disease, largely through relatively low-cost public health interventions. Of course, others would argue that Malthus’ arguments applied largely to an inorganic economy in which land was in fixed supply and the principal source of energy was the sun, and animal and human muscle power, so that when human societies began to use locked-up energy in the form of coal and oil, the constraints that Malthus took as a basis for this approach were removed. A major criticism of Malthus’ notion of famine as a positive check brought about by overpopulation is associated with the work of Amartya Sen (1981), who has suggested that few if any famines can be directly attributed to food availability declines but, rather, to institutional and market failures in delivering food to those whose entitlements were not being met. Critics have also rejected Malthus’ conservative acceptance of the political status quo and his objection to welfare from the collectivity in the form of poor relief, which he supposed undermined the willingness of populations to exercise moral restraint (Winch, 1998). More recently, historical demographers of Asia in particular have taken issue with Malthus’ inherent eurocentrism, reflected in his portrayal of China as exemplifying a high-pressure demographic regime in which unrestricted fertility and high mortality brought about recurrent crises as populations grew to sizes far too large for their food base (Lee and Feng, 1999). Such critics emphasize the role of breast-feeding, birth spacing and infanticide as means of constraining reproduction, notwithstanding early marriage of women, and stress the presence of effective welfare institutions, particularly controls on grain supplies and markets as insulation against harvest failure.

map A representation of all or a portion of the planet or some other vast environment: the typical map is graphic and includes discernible elements of scale, projection (see map projection) and symbolization. As this definition suggests, delineating the notion of map is hardly straightforward (Andrews, 1996). For one thing, not all maps are graphic, and even though the term is derived from the Latin mappa (the cloth-paper on which early maps were inscribed), not all graphic maps are drawn or printed on paper. Aerial photography and remote sensing gave rise to the image map, which has scale, projection and symbol-like tones, and readily becomes a cartographic map with the addition of line symbols or feature names. Digital cartography introduced the digital map, which can be queried and analysed by a geographic information system (GIS) without ever creating a graphic image. Definitions that include the territory mapped are problematic insofar as telescopes and rocketry, in making possible maps of the Moon, Mars, other planets or various asteroids (not to mention representations of the solar system, galaxies and the universe), have rendered ‘graphic representation of Earth’ inaccurately narrow. Robinson and Petchenik (1976, p. 16), who worried that ‘representation of the environment’ might unduly privilege physical features, contrived the relatively neutral but rarely used ‘graphic representation of the milieu’. Harley and Woodward (1987, p. xvi), in promoting the history of cartography (see cartography, history of) as a scholarly endeavour, offered the comparatively wordy definition ‘graphic representations that facilitate a spatial understanding of things, concepts, conditions, processes or events in the human world’, which concisely describes the focus of most contemporary scholars who claim cartography as a specialization. As this last definition implies, academic cartographers study not only cartographic artefacts but also the process of mapping and its impacts.

All map images have three principal elements: scale, projection and symbolization. Scale is defined as the ratio of distance on the map to the corresponding distance on the
MAP

When recorded as a ratio or fraction, a map’s scale expresses these two distances in identical units of measurement, with map distance reported first as one unit, as in 1:10,000 or 1/10,000, which means that a centimetre on the map represents 10,000 cm on the ground. (A dimensionless number, 1/10,000, also indicates that an inch on the map represents 10,000 in on the ground.) Fractional representations of scale afford a distinction between large scales such as 1/5,000 and small scales with huge denominators. Scale may be expressed verbally, as in ‘one inch represents one mile’, which some users might find more helpful than the equivalent ratio 1:63,360 (Goodchild and Proctor, 1997). Maps often include a graphical scale, on which a carefully measured line, perhaps subdivided with appropriately labelled ticks, portrays one or more typical distances. Unlike ratio or verbal scales, a graphical scale remains true when the map is photocopied at a larger or smaller scale.

Cartographic scale is occasionally confused with geographical scale, which refers to the areal extent of a physical or human process or phenomenon (see scale). Physical geographers study entities that range in size from the small drainage basin in which soil permeability affects stream discharge to the global stage of atmospheric circulation and climate change. Social, political and economic processes also involve a range of scales, in which a specific process or phenomenon is usually associated with a particular level in a hierarchy ranging from ‘local’ to ‘global’, perhaps with intermediate levels labelled ‘provincial’, ‘national’ and ‘continental’. When a geographical phenomenon is represented graphically, cartographic scale is typically determined by the size of the page, map sheet or display screen as well as the map’s geographical scope; that is, the area to be covered. That a map with a broad geographical scope typically has a small scale, while a map with a narrow geographical scope often has a comparatively large scale, underscores the inverse relationship between geographical scale and cartographic scale.

When a major portion of the planet is represented on a flat map, scale will vary markedly, not only from place to place but also with direction (see Map Projection). The latter distortion is particularly obvious on rectangular world maps, on which the poles are as long as the equator, while angles and small shapes are noticeably more distorted in poleward regions than at lower latitudes. A noteworthy exception is the Mercator projection, which is conformal, meaning that scale at a point is the same in all directions, even though scale varies enormously across the map. Devised to solve a specific problem in navigation by rendering lines of constant geographical direction as straight lines, the Mercator projection famously enlarges the size of mid-latitude countries, relative to tropical nations, and because north–south scale equals east–west scale everywhere, the poles lie at infinity. While its conformality makes the Mercator projection an acceptable choice for large-scale maps with a comparatively small geographical scope, it is a poor framework for world maps that have nothing to do with navigation.

Because a map’s projection determines the type and pattern of distortion, and thus affects the viewer’s perception of size, shape, distance and direction, selecting an appropriate projection is a crucial decision for the map author (Canter, 2002). An appropriate projection is especially important for a world map, which should never include a graphical scale because extreme distortions are unavoidable. For most thematic maps, a projection that preserves relative area is desirable, although the more extreme distortions of shape found on equal-area maps of the whole world can be mollified by a compromise framework such as the Robinson projection, which attempts to balance distortions of area and angles (Ipbuker, 2004). The point or line at which a whole-world map is centred is also important, not only because distortion is usually low near the centre but also because territories thus favoured might be perceived as more important or accessible than those on the periphery. Another useful compromise is the interrupted projection, typified by Goode’s homolosine equal-area projection, which partitions the world map into six lobes, for which separate, locally centred projections minimize shape distortion for continents and coastlines.

The third principal element of a map is the graphic coding of geographical features, or symbolization. Although labels that connote land masses, oceans and cities can expedite decoding, standardized symbols that draw on cartographic conventions, such as blue for hydrographic features and green for vegetation, are especially helpful for at-a-glance assessments of their extent. Also useful are logical linkages between a map’s content and the six ‘retinal variables’ readily manipulated by the map author. As defined by Bertin (1983), non-verbal cartographic symbols typically vary in shape, pattern, hue, orientation, size and greytone value, each of which is
especially suited for portraying a particular kind of geographical variation. For example, hue, related to wavelength of visible light and often associated with named colours such as red and green, is appropriate for representing qualitative differences among, for example, various categories of land use. Bertin’s rationale was straightforward: because red, green, and yellow look different to persons with normal color vision, they are ideal for mapping differences in kind, especially for area features large enough to require discernible patches of hue. Similarly, readily recognized differences in form among point and line symbols make shape an appropriate visual variable when a map must distinguish churches from schools and footpaths from railways. By contrast, quantitative data are better represented with symbols that vary in size or greytone value; that is, relative darkness. Viewers are well served by map authors who distinguish between count or magnitude data such as total population or number of employees, and intensity data such as population density or the proportion of the labour force unemployed. With count data, for example, point symbols that vary in size support a logical larger-means-more metaphor that promotes comparisons without looking repeatedly at the map key, whereas for intensity data symbols ranging from white to black support an equally obvious darker-means-more decoding rule (Monmonier, 2005). Although symbols that vary in direction are logical for representing phenomena such as wind direction and one-way streets, pattern variation is largely limited to dashed-line symbols and area symbols, such as the arrays of dots that connote orchard land and vineyards on topographic maps. Dynamic cartography has produced additional visual variables, notably the duration, rate of change and order of scenes (DiBiase, MacEachren, Krygier and Reeves, 1992).

Because place and feature names use natural language to link cartographic symbols to specific locations, typography is another important part of the map’s symbolic code (Wood, 2000). And because type comes in various shapes and sizes, map labels reflect conventions such as the use of italic type for hydrographic features as well as an extension of Bertin’s theory of retinal variables. Although aesthetic dictates that map authors avoid using numerous typefaces to represent qualitative differences among places or features, style variations (roman/italic, all-uppercase/initial capitals, bold/plain, underlining) support the typographical coding of differences in kind, whereas type size affords a readily decoded representation of magnitude. Some reference maps use a redundant coding in which the sizes of point symbols and their labels offer a mutually reinforced treatment of population size.

Names on maps can have deep cultural-political significance, especially when conquest or revolution allows the victor to rename places and geographical features, and even install a new language or orthography (writing system). As illustrated by the renaming and re-renaming of St Petersburg in Russia, control of a country’s official cartography presents an irresistible opportunity to underscore the loser’s defeat by replacing its toponyms (place names). As pervasive symbols of domination, names on map and road signs can arouse resentment as well as inspire alternative cartographies similar to the Palestinian maps of Israel, rendered crudely in Arabic atop photographic copies of official maps (Kadmon, 2000, pp. 80–1). And because maps reveal otherwise obscure, pejorative feature names inherited from earlier, less politically sensitive times, they can trigger the belated removal of names (Monmonier, 2006). Recent disputes over cartographic labels have focused on waters separating feuding countries (e.g. Sea of Japan/East Sea, Persian Gulf/Arabian Gulf), the toponyms and orthography of indigenous peoples (e.g. in Hawaii and northern Canada) and a country’s right to police the rendering of its name beyond its borders (e.g. Macedonia and Myanmar, both resisted by the USA).

Because cartographic scale is usually too small for an exact treatment of shape and other geometric relationships, maps are almost always generalized, even large-scale maps of small areas (Buttenfield and McMaster, 1991). Cartographic generalization begins with the selection of features, some of which represent the phenomenon portrayed while others provide a frame of reference linking new information to the viewer’s existing understanding of the region mapped. For example, coastlines, national BOUNDARIES and highway networks are common frame-of-reference features on maps not explicitly concerned with coastal geomorphology, GEOPOLITICS or transportation. Map authors must select features carefully, because legibility often requires line and point symbols proportionately thicker than the features portrayed. For instance, a road five metres wide represented on a 1:50,000 map by a barely visible line one millimetre thick occupies a cartographic
corridor corresponding to a ground swathe 50 metres across. Because the exaggeration is much greater at very small scales as well as for boundaries and contour lines, which in principle have no width, the map author must not only eliminate less significant features but also smooth out meandering streams and contorted coastlines, displace symbols that would otherwise overlap, and replace the intricate boundaries of small cities with tiny circles (Dutton, 1999). Visibility and coherence might also require, as examples, the widening of narrow entrances to important bays, the exaggeration of an important kink (jog) in a road, the amalgamation of distinct but adjoining patches for forested land, and the blurring of distinctions between diverse types of cropland. Additional accommodations are often needed to create room for important labels – although well-known abbreviations can shorten street and feature names, failure to label key features invites confusion or misinterpretation.

Generalization can be especially problematic with statistical maps, which are notorious for using aggregated counts or averages to describe trends in census data. A uniform area symbol for a large, inherently diverse nation or county can suggest an unwarranted homogeneity as well as dilute coherent patterns obvious on maps with smaller, more reliable areal units (Crampton, 2004). Potentially troublesome are choropleth maps, readily generated with commercial, off-the-shelf mapping software that arbitrarily chops the range from lowest to highest data values into five equal intervals, which are then portrayed with a spectral sequence of hues (blue, green, yellow, orange, red) that defies the logical darker-spectral sequence of hues (blue, green, yellow, orange, red) that defies the logical darker-
spectrums correspondence between diverse types of cropland. Additional accommodations are often needed to create room for important labels – although well-known abbreviations can shorten street and feature names, failure to label key features invites confusion or misinterpretation.

Maps can be categorized in numerous ways, to reflect their content (e.g., topographic map, street map), symbolization (e.g., choropleth map), intended use (e.g., cadastral mapping, road map), publisher (e.g., government map, commercial map), format (e.g. wall map, atlas map, newspaper map) or medium (e.g. paper map, video map). Especially noteworthy are several new map forms that emerged solely or largely during the twentieth century. Image maps, rooted in the invention of the hot-air balloon and photography in the eighteenth and nineteenth centuries, became an important mapping technology with the development of fixed-wing aircraft, helicopters and artificial satellites, as well as customized cameras and electronic scanners used in remote sensing (Dahlberg, Luman and Vaupel, 1990). Also known as photomaps, image maps have become a valuable supplement to the conventional topographic 'line map', so called because features are inscribed by crisp symbols rather than inferred from tonal contrast. Although a single aerial photograph is a perspective view, with distances distorted locally by variation in elevation, photogrammetry allows the compilation of topographic maps from overlapping aerial photographs as well as the efficient generation of distortion-free, 'orthorectified' photomaps (as in Google Earth: www.earth.google.com).

Electronic technology has radically altered the appearance and usability of maps. Animated maps, first produced on film but now generated by software, treat time as a scalable entity and afford historical maps with two scales, for example, ‘ten seconds represents one year’ for time and ‘one inch represents five miles’ for distance (Harrower, 2004). Dynamic maps afford dramatic fly-by renderings of terrain or statistical surfaces, while interactive topographic maps overcome conventional treatments of scale and generalization by letting viewers zoom in or out. Interactive maps that let users retrieve additional information by clicking on or merely rolling over a symbol can remove the inherent uncertainty of categories on a choropleth map, or promote a fuller understanding of an unfamiliar country or a local hazardous waste site (see Visualization). The Internet not only expedites the delivery of geographic information, such as timely radar weather maps, but also affords instant access to historic maps in public archives and free, advertiser-supported route maps with supplementary verbal directions. Societal impacts are especially apparent in Web-based deliberative mapping, which fosters negotiated solutions of planning or political issues by multiple authors (Wiegand, 2002), and in a ‘cybercartography’ that promises a wider exploitation of multi-sensor formats, an unprecedented degree of integration and customized products, and inevitable challenges for designers, politicians and scholars (Taylor, 2003). (See also Map Reading.)

**Map projection** A geometric transformation of the spherical world on to a flat map. Map
projection is readily understood as a two-stage process that begins by shrinking the world to a hypothetical globe, which establishes the map’s stated scale. The second stage develops an azimuthal, a conic or a cylindrical projection by transferring meridians, parallels, coasts and boundaries on to, respectively, a plane, cone or cylinder. Each of these three developable surfaces has a distinctive grid of meridians and parallels. Sometimes a third stage readjusts locations and shapes, as when the sinusoidal projection corrects for the enlarged poleward areas on a cylindrical projection by bending meridians inward towards a central meridian.

Because of unavoidable stretching, compression or shearing, map scale generally varies from place to place across the projection as well as with direction at a point. On a cylindrical projection, for instance, scale in the north-south direction might be constant while east-west scale grows indefinitely large near the poles. In general, scale will equal the stated scale only at the point, line, or lines of contact between the globe and the developable surface. Moreover, distortion increases with distance from the tangent point or standard line, the location of which positions a zone of comparatively low distortion. Allowing the developable surface to penetrate the globe provides a ring of low distortion on an azimuthal projection and two zones of low distortion on a conic or cylindrical projection. A map author can tailor a projection to a specific country or region by carefully selecting the developable surface and its orientation to the globe (Robinson and Snyder, 1991; Canters, 2002).

Many perspectives and orientations are possible. Although all projections distort most distances, an equidistant projection might preserve true distance from the Equator, one of the poles or some other point of interest. Similarly, an equivalent projection can preserve the true relative areas of countries and continents, whereas a conformal projection, which preserves small shapes as well as angles around points, is especially useful on large-scale maps of small areas. Unfortunately, equidistance, equivalence and conformality are mutually exclusive.

Because the mapped area of a country or region can be seen as signifying its importance, the well-known Mercator projection, which significantly reduces the relative size of tropical nations, has been attacked as biased and eurocentric, with the most strident objections emanating from proponents of the Gall–Peters projection, an equal-area map touted as ‘fair
to all peoples’ despite severe north–south stretching in the Tropics and comparatively reliable shapes and angles across western Europe and the northern USA (Monmonier, 2004b). Several other equal-area projections offer a more balanced pattern of shape distortion, and numerous compromise projections attempt to balance distortions of area and angles. Map authors eager to focus on people, rather than land area, can map socio-economic data on a cartogram, on which area represents population (Tobler, 1963).

map reading The process of extracting information from a map, which is fundamental cartographic practice (see Cartography). Textbooks on the reading and use of maps and globes were produced from the 1500s onwards, as a required part of a noble or genteel education. After 1650, they became a mainstay of public discourse and, after 1800, of regularized primary education in centralizing European states. Exercises in map-reading were integral to Heimatkunde, the initial stage of the formal curriculum in geography adopted in German primary schools after 1871 and subsequently emulated throughout western Europe and Japan. After 1900, the interpretation of larger-scale topographical maps developed as a key skill for the study of landscapes within both academic geography and the military (cf. military geography). Militaries have generated a variety of technical manuals, and military-orientated tasks dominated the curricula of introductory map-reading courses in many US universities after the Second World War. The needs of the military also drove academic research in cartography and human geography into the cognitive processes of map reading to support the production of maps that could be read easily and effectively, while behavioural geography included research into the development of map-reading skills among children and adults (and also their production of mental maps).

In all these circumstances, map reading has been understood as comprising four tasks, regardless of map scale:

(1) the identification and location of particular places;
(2) navigation, which entails route-selection, position-verification and anticipation of the future;
(3) the identification of patterns, distributions and morphologies of spatial features;
(4) the cartometric endeavours of taking measurements from maps, whether as simple as determining distances or areas or as complex as the statistical analysis of a map’s geometrical accuracy (Maling, 1989).

These tasks have all been applied to old as well as modern maps (see Cartography, History of). In terms of ontology, such map-reading practices sustain the modern ideology of cartography (see also Cartographic Reason). Their repeated performance within authoritative state institutions has naturalized the expectation that maps are intended to be used only in such specific ways. (The automatic reaction to critical approaches to cartography is thus to appeal to the functional authority and so legitimation of the road map.)

Against this limited and only partially adequate perspective, recent critics have sought to read maps as cultural documents, to elucidate their cultural and social significance (Edwards, 2003). Two approaches are especially rewarding. Strongly influenced by art-historical studies in iconography, Harley (2001b) construed maps to comprise two layers of meaning: an overt layer of factual data, directly accessed through standard map-reading techniques, and an obscured layer of cultural meaning to be elucidated through identification and consideration of a map’s conventional and iconological symbolism. Wood and Fels (in Wood, 1992, pp. 95–142) advanced a more systematic analysis of maps as semiotic systems in their reading of a common road map; their essay has deservedly become the paradigm of critical map interpretation. Even so, their analysis of the differential and structured deployment of signs was preliminary. That is, the desideratum of a comprehensive and rigorous methodology for reading maps as cultural documents remains to be completed. (See also Culture.)

market The market is indisputably an example of what Raymond Williams (1976) called a ‘keyword’. It is as a consequence rather complex, its meanings have been unstable historically, and its use and deployment always ‘inextricably bound up with the problems it was being used to discuss’ (p. 15). Adam Smith famously noted that there was an intrinsic human propensity to truck, barter and
MARKET

exchange things – in other words, to commodify the world through active participation in markets (cf. ECONOMY). Yet one of the great paradoxes of contemporary economics is that most textbooks do little to dispel the notion that markets are magical or supernatural, reflecting the extraordinary (and sometimes utopian) powers of the hidden hand. None other than Nobel Laureate Ronald Coase noted that markets had a ‘shadowy role’ in economic theory at least until they attracted the attention of other Nobel Laureates such as George Akerlof and Joseph Stiglitz (see McMillan, 2002).

How, then, is the term ‘market’ deployed? One meaning is resolutely empirical and geographical: it is a ‘public place where a market is held’, where the latter is ‘a meeting together of people for the purpose of trade by private purchase and sale’ (Online Merriam-Webster Dictionary). In this sense, of course, markets have a very deep history – commodities exchanged through some medium (money) – extending back millennia. Numismatic research suggests that while there were no formal markets as such, proto-monies facilitating exchange may date back 10,000 years; gold coins were certainly in circulation 2,500 years ago in Turkey, and the Sumerians had made use of silver bars as a money 2,000 years earlier. Markets are also in the business of commodity circulation. Markets facilitate and promote generalized commodity circulation.

The multiplication of markets – the purchase and sale of virtually everything – implies commodification and the expansion of the commodity frontier to every nook and cranny of the world we inhabit (Williams, 1983 [1976]). Even if some domain of our social world remains immune to the deadly conceits of the market, the extent to which the logic of the marketplace has insinuated our culture and social life is historically unprecedented: we do not as a matter of right or principle buy and sell children, and yet human organs, sperm and ova can and are part of brisk market exchanges. There can even be markets in abstractions and fictions – in climatic risk, in future bundles of currencies, in derivatives.

Yet this dictionary definition is superficial, because it says little of what actually constitutes – and what are the conditions of possibility of – market transactions. Most economists – influenced by transaction cost analysis, by the studies of economic norms, and by the institutionalism of some forms of neo-classical economics (see Williamson, 1985) – identify decision-making autonomy and participation as key to market operations: buyers and sellers willing participate in the exchange and can veto any deal (McMillan, 2002). The purported ‘freedom’ of the market – buyers and sellers controlling their own resources and not acting under (extra-economic) compulsion – turns on choices and preferences subject to certain constraints (on their resources and the ‘rules’ of the market). Several aspects of this definition are important. First, where an authority relationship shapes the transaction, it is not a market transaction (it is another sort of transaction: administered or forced or perhaps black market). Second, for the poor the degrees of freedom, participation and choice are very constrained. Bargaining power between buyer and seller is unequal, yet economists would see the right of veto as ‘a kind of freedom’. Third, while competition is not a defining feature of the market (markets might be oligopolistic), there is a presumption that adds to autonomy (by virtue of there being alternatives). As a consequence of these attributes, a market transaction is typically defined as:

An exchange that is voluntary; each party can veto it, and (subject to the rules of the market place) each freely agrees to the terms. A market is a forum for carrying out such exchanges. (McMillan, 2002, p. 6)

Market transactions defined in this way are, of course, limited: markets are never wholly ubiquitous and there are realms in which the reach of the market is limited even in advanced capitalist states. Many of the transactions within households, within firms and within governments are not market transactions as defined conventionally. Yet these non-market transactions take place within a universe of dominant market transactions and indeed are directly and indirectly shaped by the powerful logics of the operations of the market. It is also clear from the definition of market transaction that markets are always in a limited sense ‘free’. They always have rules, more or less formal. They require patterns of trust and social convention. And, not least, they demand the role of government in defining property rights, and typically providing complex bodies of law pertaining to contracts. All of this endorses the idea that there are many different forms of markets, that market transactions presuppose quantities and qualities of information (often unevenly available – information asymmetries is the neo-classical argot), and that market transactions
may be wildly different in their costs to buyer and seller alike.

When Simmel (1978) noted that exchange is one of the ‘purest and most primitive of forms of human socialization’, he endorsed the idea that a market is a social construction. As Stanford economist John McMillan puts it: for markets to work they must be ‘well built’: the field of market design, accordingly, refers to the analysis and pragmatics – the purposeful building – of institutions for transacting market exchanges. As McMillan says:

Market design consists of the mechanisms that organize buying and selling; channels for the flow of information; state-set laws and regulations that define property rights and sustain contracting; and the markets culture, its self-regulating norms, codes and conventions governing behavior . . . A workable design keeps in check transaction costs . . . Transaction costs are many and varied. (2002, p. 9)

And yet even in acknowledging these properties, it is not unusual to hear the claim from economists that ‘no one is in charge of the market’ (McMillan, 2002, p. 7). And to this extent, as Vaclav Havel once put it, the market ‘is the only natural economy’. This, of course, raises another meaning of market that is both ideological and political (see ideology). In addition to markets and market transactions, there is the idea of ‘the market’, or ‘the market system’ or ‘the free market’. It is an abstract notion – abstracted from the actual interactions and functionings of many different forms of market – but one that arises in a particular moment – its modern founding charter is associated with Adam Smith’s The wealth of nations – and it has a long and complex history. Smith was fully aware of the fact that markets had their limits, that government provisions and public goods were indispensable to the operations of markets, and that markets left to their own devices could in fact be destructive. And yet he retained the ideological notion that markets were natural – rooted in human impulses to truck, barter an exchange. There is, of course, an alternative narrative. Even at the time of Smith’s writing, his world was awash with the operations of a distinctively moral economy that privileged use-value above exchange-value (Thompson, 1991) and of claims for a just price. Popular reactions in defence of an arena that was seen to be beyond the market – the commons – defined much of what passed as politics (Neeson, 1993). At the very least, then, the modern market was not so much natural as the product of struggle. And it is a struggle that is central to the operations of the market in the twenty-first century. The global commons represent a frontier of contemporary resistance to – and shaping of – the rules of the market (Saad-Filho and Johnson, 2005).

The contested nature of markets – in the details or their operations or as a utopian vision – is central to any understanding of economy, liberalism and modernity (Harvey, 2005). Karl Polanyi’s The great transformation and Friedrich Hayek’s The road to serfdom were both published in 1944. Hayek, an Austrian economist trained at the feet of Ludwig von Mises, but forever associated with a largely non-economic corpus produced at the London School of Economics and the universities of Chicago and Freiburg between 1940 and 1980, is widely recognized as one of the leading intellectual architects of the neo-liberal counter-revolution (see neo-liberalism). Margaret Thatcher pronounced that ‘this is what we believe’ as she slammed a copy of Hayek’s The constitution of liberty on to the table at Number 10 Downing Street during a Tory Cabinet meeting. Hayek’s critique of socialism – that it destroys morals, personal freedom and responsibility, impedes the production of wealth and sooner or later leads to totalitarianism – is the ur text for market utopians. Collectivism was by definition a made rather than a grown order: it was, Hayek said, constructivist rather than evolutionary, organized not spontaneous, a ‘taxis’ (a made order) rather than a ‘cosmos’ (a spontaneous order), an economy rather than a ‘catal- laxy’, coerced and concrete rather than free and abstract (see Gamble, 1996, pp. 31–2). Its fatal conceit was that socialism (and social democracy for that matter) admitted the ‘reckless trespass of taxis onto the proper ground of cosmos’ (Anderson, 2005b, p. 16).

The other half of Hayek’s project was a robust defence of Western civilization – that is to say of liberty, science and the spontaneous orders that co-evolved to form modern society (‘Great Society’, as he termed it). It was a buttressing of the liberal (unplanned) market order from which the preconditions of civilization – competition and experimentation – had emerged. Hayek, like Weber, saw this world as an iron cage constituted by impersonality, a loss of community, individualism and personal responsibility. But unlike Weber, Hayek saw these structures, properly understood, as expressions of liberty. From the vantage point of the 1940s this (classical) liberal project was, as
Hayek saw it, under threat: what passed as liberalism was a travesty, a diluted and distorted body of ideas corrupted by constructivist rationalism (as opposed to what he called ‘evolutionary rationalism’). The ground between liberalism and much of what passed as Keynesianism or social democracy was, on the Hayekian account, catastrophically slight. What was required, as he made clear at the founding of the Mont Pelerin Society in 1947, was a restoration, a purging of true liberalism (the removal of ‘accretions’). There was to be no compromise with collectivism: the seized territory had to be regained. In his writing and his promotion of think-tanks such as the Institute of Economic Affairs in Britain – the brains trust for the likes of Keith Joseph and Margaret Thatcher – Hayek aggressively launched a cold war of ideas. He was part of the quartet of European theorists (Carl Schmitt, Leo Strauss and Michael Oakeshott were the others) whose ideas, while standing in a tense relationship to one another, have come to shape a large swath of the intellectual landscape of the early twenty-first century (see Anderson, 2005b). Hayek was neither a simple conservative or libertarian, nor a voice for laissez-faire (‘false rationalism’, as he saw it). He identified himself with the individualist tradition of Hume, Smith, Burke and Menger, thereby providing a bridge that linked his short-term allies (conservatives and libertarians) to classical liberals in order to make common cause against collectivism (Gamble, 1996, p. 101). To roll back the incursions of taxis required a redesign of the state. A powerful chamber was to serve as guardian of the rule of law (striking all under 45 years off the voting roll), protecting the law of liberty from the logic of popular sovereignty. As Anderson (2005a, p. 17) notes, the correct Hayekian formula was ‘demarchy without democracy’.

Karl Polanyi was a Hungarian economic historian and socialist who believed that the nineteenth-century liberal order had died, never to be revived. By 1940, ‘every vestige’ of the international liberal order had disappeared, the product of the necessary adoption of measures designed to hold off the ravages of the self-regulating market (market despotism). It was the conflict between the market and the elementary requirements of an organized social life that made some form of collectivism or planning inevitable (Polanyi, 1944). The liberal market order was, contra Hayek, not ‘spontaneous’ but a planned development, and its demise was the product of the market order itself. A market order could just as well produce the freedom to exploit as it could the freedom of association. The grave danger, in Polanyi’s view, was that liberal utopianism might return in the idea of freedom as nothing more than the advocacy of free enterprise, the notion that planning is nothing more than ‘the denial of freedom’ and that the justice and liberty offered by regulation or control becomes nothing more than ‘a camouflage of slavery’ (1944, p. 258). Liberalism in this account will always degenerate, ultimately compromised by an authoritarianism that will be invoked as a counterweight to the threat of mass democracy. Modern CAPITALISM contained the famous ‘double-movement’, in which markets were serially and coextensively disembodied from, and re-embedded in, social institutions and relations – what Polanyi called the ‘discovery of society’. In particular, the possibility of a counter-hegemony to the self-regulating market could be found in resistance to the commodification of the three fictitious commodities (land, labour and money): such reactions represented the spontaneous defence of society (Burawoy, 2003).

The market and anti-market mentalities of Hayek and Polanyi were both forged in the context of FASCISM, global economic depression, revolution and world war. To look back on the birth of The great transformation and The road to serfdom from the perch of 2008 is quite salutary: we see AMERICAN EMPIRE (military neo-liberalism), a global ‘war on terror’ (see TERRORISM), the dominance of unfettered global finance capital, a worldwide Muslim resurgence, a phalanx of ‘failed states’ (otherwise known as the failure of secular nationalist development) and a raft of so-called ANTIGLOBALIZATION movements, and the rise of civic regulation. There has been, intellectually speaking, a consequent Polanyi boom (see Williams, 2005a) within the academy, but fewer careful readings of the Hayekian ideas that helped spawn these developments. From within the bowels of this turmoil, the Hayekian vision is triumphant – the Liberal International has come to pass. Its long march, from Mont Pelerin to the collapse of the Berlin Wall and TINA (‘There Is No Alternative’) took about forty years and, according to Harvey’s (2005) brief history, passed through the Chicago Boys in Chile, the IMF/IBRD complex, the Reagan–Thatcher revolutions and the corporate (class) seizure of power in the 1970s against a backdrop of declining profitability and income share. Even if ‘global neo-liberalism’ has now assumed a neo-conservative and military cast (Saad-Filho
In other words, tracing the ways in which neoliberalism ruling undivided across the globe as the most successful ideology in world history (Anderson, 2002c). This ‘fluent vision’ of the Right has no equivalent on the Left: Anderson cedes that embedded liberalism (let alone something called socialism) is now as remote as ‘Arian bishops’, resistances are like ‘chafe in the wind’ and the Left can only ‘shelter under the skies of infinite justice’. Of course, with the vertiginous collapse of Wall Street and a raft of financial institutions in late 2008, followed by the massive bailouts initiated by various governments in Europe and America, Anderson’s grand slam now looks very different.

The very process by which neo-liberal market hegemony was established – and against which forms of RESISTANCE are to be assessed – remains a story for which at present we have no full genealogy. The cast of characters may be lined up – from the school of Austrian economics to the Reagan–Thatcher–Kohl troika – but this explains very little. Neoliberalism can be seen as a CLASS reaction to the CRISIS of the 1970s. The global multilaterals and the Treasury–Wall Street certainly imposed brutal forms of economic discipline – STRUCTURAL ADJUSTMENT – to eradicate forever any residue of collectivism in the Third World. But beyond these general descriptions we are left with paradoxes and questions, of which I will list just a few. Why did the LSE and Chicago – the centres of Fabianism and a certain sort of American liberalism – become the forcing houses of neo-liberalism? Hayek, after all, was not associated with the Economics Department; it was the arrival of Ronald Coase at Chicago that marked a neo-liberal turning point. How did the World Bank – a bastion of postwar development economics and a certain sort of statism – become the voice of laissez faire? Harry Johnson (who held Chairs at the LSE and Chicago) certainly figures in the process, but how can we explain economic liberalism’s capture of key sectors of the Bank (often by second-rate economists) against a backdrop of robust Keynesianism? How did the ideas of economists such as Peter Bauer and Deepak Lal gain traction? Criticism of Keynes dovetailed with the anti-statism levelled by many on the Left during the 1970s. In other words, tracing the ways in which government failures came to outweigh market failures in development thinking demands a complex picture of discursive contestations and political practices. Indeed, by the mid-to late 1970s many of neo-liberalism’s intellectual architects (Milton Friedmann among them) claimed that nobody took their ideas seriously – Hayek believed that The road to serfdom had ruined his career and marginalized his entire project. It was the inflation of the 1970s, said Friedmann, that revealed the cracks within the Keynesian edifice. The point is that the ‘neo-liberal grand slam’ was preceded by decades of mediocrity, pessimism and contestation, and that the class forces around and through which embedded liberalism had been built necessarily shaped the manner and forms in which the counter-revolution could proceed (if at all). How to think about the power of the market now turns on how one sees this long march through institutions. The catastrophic collapse of the US investment banks and the discrediting of the various regulatory and financial rating agencies – with the prospect of a 1930s-style world depression in the offing – suggests that the neo-liberal project has come crashing to a halt. As the New York Times put it in early 2009, ‘we are all Keynesians now’.

**Markov process (or Markov chain)** A type of STOCHASTIC PROCESS in which the probability of being in a particular state at time \( t \) is wholly dependent upon the state(s) at some preceding time(s). It is named after the Russian mathematician who first defined the process. The simplest form, known as a first-order Markov process, is where the dependence is entirely on just the immediately preceding state. This process can be represented by a transition probability matrix in which the rows and columns represent the different states and the cells represent the probabilities of movement between states. For example, migration movements between three regions A, B and C could be modelled as follows:

<table>
<thead>
<tr>
<th>State at time ( t + 1 )</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>State at time ( t )</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A</td>
<td>0.80</td>
<td>0.15</td>
<td>0.05</td>
</tr>
<tr>
<td>B</td>
<td>0.08</td>
<td>0.90</td>
<td>0.02</td>
</tr>
<tr>
<td>C</td>
<td>0.10</td>
<td>0.05</td>
<td>0.85</td>
</tr>
</tbody>
</table>
From this we may see that, between time \( t \) and time \( t + 1 \), 80 per cent of the population in A remain there, 15 per cent move to B and 5 per cent to C, and similarly for movements from regions B and C in rows 2 and 3. By repeated operation of the matrix, the population pattern redistributes to a stable pattern independent of the initial pattern (assuming no births, deaths or movements in or out of the total system). This Markov model has been used to study population migration, epidemic processes, the growth and movement of firms, and trends in regional economic convergence and divergence, and is a component of more sophisticated demographic modelling.

Suggested readings

Marxism The body of ideas and practices developed by Karl Marx (1818–83) and greatly elaborated since his death by his followers. His voluminous writings fall into several broad categories. First, there are those writings that develop a broad theory of history (historical materialism) as a succession of modes of production, in which changes in economic and class structures play a central dynamic role. Second, there are writings (such as the three volumes of Capital) that develop a more detailed political economy of capitalism as a mode of production, using the labour theory of value to explore its underlying contradictions and tendencies to crisis. Third, there are various, more sketchy, writings on dialectical philosophy and method (see dialectics). Fourth, there are a wide range of analyses of contemporary events, often designed to illustrate broader theories (such as The eighteenth brumaire of Louis Napoleon), polemical addresses and a mass of journalistic writings for various newspapers.

Marx did not present a single, codified version of his ideas, which in any case changed over the course of his lifetime. Some later Marxists, such as Louis Althusser (see Althusser and Balibar, 1970), have even claimed to detect a major ‘epistemological break’ in his work between the earlier more philosophical and ‘humanist’ texts, strongly influenced by Hegel, and the later, more ‘scientific’, analyses of political economy. Gouldner (1980) also sees a distinction between a younger and older Marx, but more in terms of a tension between a voluntaristic ‘Critical Marxism’ and a more deterministic ‘Scientific Marxism’. Even those (the majority of commentators) who prefer to stress the underlying continuities in his work differ in the emphases they place on different themes and texts. As a result of such multiple possible readings, Marxism has become more a family of theories with many strands than a single codified framework. This is part of its attraction and contributes to its continuing vitality.

Histories of Marxism usually identify several phases of development and divergence (McLellan, 1979). The first codified version of ‘orthodox Marxism’ was developed after Marx’s death by Engels, Kautsky, Bernstein and Plekhanov, who published systematic expositions of historical and dialectical materialism, the nature of capitalism and the theory of revolution. Lenin subsequently adapted Plekhanov’s orthodox ‘stages’ view of history to justify revolution in a backward capitalist state such as Russia. However, with the degeneration of the revolution and the onset of Stalinism, ‘Marxism–Leninism’ rapidly hardened into the official ideology of the centralized Soviet state.

The Western Marxism of Lukacs, Korsch, Gramsci and the Frankfurt School (Horkheimer and Adorno) was developed partly as a reaction against this dogmatism, shifting the emphasis away from political economy more towards neglected aspects of culture, ideology and art. A return to Hegel and his influence on Marx provided an underlying philosophical thread to this work (see also critical theory).

The post-Second World War period has been marked by increasing internal diversity within the Marxist tradition, as Marxists have responded to, and interacted with, other developments in philosophy and social theory. Jean-Paul Sartre tried to blend a reinterpretation of Marxism with the philosophy of existentialism. Althusser developed a re-reading of Marxism – indebted, in part, to structuralism – that attempted to save Marxism from what he regarded as the twin deviations of historicism and economism. Althusserian Marxism presented a science of social systems, with a relative autonomy of levels ‘structured in dominance’ and an economy only ‘determinant-in-the-last-instance’.

Althusser’s structuralism provoked strong reactions, leading to a proliferation of new currents over recent decades. Harvey (1999 [1982]) has preferred to go back to Marx’s own writings, demonstrating the continuing potential of an essentially ‘orthodox’ version of Marxism. The architects of analytical Marxism, such as Cohen, Roemer and Elster (Mayer, 1994), have sought to build
micro-economic foundations for Marxism using rational choice theory, and to displace dialectics with analytical philosophy and the labour theory of value with neo-classical economics. Realist Marxists have sought to provide a stronger philosophical shell for Marxism by drawing upon recent developments in the philosophy of realism (Brown, Fleetwood and Roberts, 2002). Anti-essentialist Marxists have sought to expunge the last remnants of economic determinism from Althusserian Marxism (Resnick and Wolff, 1987; cf. essentialism) and ‘postmodernist Marxists’ such as Laclau and Mouffe (1985) have tried to find a rapprochement with Jacques Derrida’s deconstruction (see also postmodernism; post-structuralism). Whether many of these lines of development are still definably ‘Marxist’ or whether they are ‘post-Marxist’ is an open, and perhaps irrelevant, question.

Indeed, some of the most interesting work is being generated through dialogues and critiques across boundaries, such as Deleuze and Guattari’s (1984) conjunction, in Capitalism and schizophrrenia, of Sigmund Freud, Marx and Baruch Spinoza, or critical realist attempts to find complementarities between Marx and Michel Foucault (Marsden, 1999) or Hardt and Negri’s fusion of elements from Marx, Gilles Deleuze and Spinoza in their Empire (2000). There have also been vital engagements with human geography. Many geographers have been influenced by the discipline’s remarkably late reading of Marx: most other social sciences – notably anthropology, economics and sociology – had a much longer history of coming to terms with Marx and Marxism, but it would be a mistake to limit the influence of Marx’s writings to the ongoing project of a marxist geography, not least because so many of the other disciplines with which human geography has entered into conversation have themselves been marked by Marxism, and those traces have in turn left their own marks on geographical enquiry. There has also been a still more belated return movement, in which contemporary Marxism has started to come to terms with the core concerns of human geography. On one side, these have involved conceptual elaborations of place, space and nature that in turn require reformulations of some of Marxism’s basic postulates. Harvey (1999 [1982]) in particular has sought to re-theorize Marxism as a historico-geographical materialism capable of addressing the characteristically uneven development of capitalism (cf. production of space). On the other side, there has been a constructive critique of the ethnocentrism of not only classical Marxism (where the formalization of an ‘Asiatic’ mode of production is today an embarrassment) but of the ‘Westernness’ of Western Marxism. This has involved an appreciation of the production of substantive geographical differences, which has been made possible by studies in regional geography that have been revitalized by an engagement with a post-colonialism that has itself been inspired and provoked by Marx’s legacy. As a result of these various challenges, critiques and conversations, Marxism continues to develop as a living tradition, interacting with surrounding currents in new ways, and spinning off a variety of hybrid forms.

**Marxist economics** A heterodox field that spans the methodological gamut from structural and class-centred relational and dialectical approaches to individual-centred rational choice approaches. If something called ‘Marxist economics’ coheres, it is because of what it is not – namely, neo-classical economics (however, subsets of rational choice Marxism that seek to give Marxist economics a ‘micro-foundation’ – these would include the projects of Adam Przeworski, Samuel Bowles, Herbert Gintis or John Roemer – veer perilously close to post-Walrasian variants of neo-classical theory). In the simplest formulation, Marxist economics, unlike its neo-classical counterpart, views individuals as social beings: as such, it emphasizes social structure more than individual behaviour. It draws attention to class struggle, which, it contends, is interwoven with every other aspect of society in complex and contradictory ways. The economy is understood as a terrain where class exploitation occurs and exerts its powerful influence over the rest of social life. ‘Exploitation’ is a key operator in most versions of Marxist economics, and refers to a ‘class process in which the person who performs surplus labor is not also the person who appropriates it’ (Wolff and Resnick, 1987, p. 167). Note that the description of Marxist economics so far is not confined to the analysis of capitalism.

The historian Robert Brenner, for example, has offered a remarkable class-based analysis of the jagged transition from feudalism to early capitalism in Western Europe and convincingly illustrated the generality of Marxist economics as a framework for understanding economic crises and growth cycles. Parting company with those rational-choice Marxists...
who claim that the institutional preconditions of economic growth are the outcome of (parametric or strategic) actions undertaken by sovereign economic actors (see Carver and Thomas, 1995), Brenner instead contends that it is unwarranted ‘to take for granted a society of free economic actors, rather than one of economic actors subject to non-economic constraints’ (Brenner, 1986, p. 25). Second, rationally self-interested action in such circumstances will, as a rule, exhibit the goal of maintaining existing property relations, thereby impeding economic development; and, third, should economic development occur, it must be viewed – in light of the second premise – ‘as an unintended consequence of . . . conflicts between [antagonistic] classes’ (ibid., p. 26).

The distinctive contribution of geographers to Marxist economics has been to show that capitalist dynamics are intrinsically geopolitical. Thus, radical geographers such as David Harvey and Doreen Massey have demonstrated, in quite different ways, how class relations involving the extraction of surplus labour are stretched out spatially and profoundly implicated in differing patterns of uneven development – whether locally, regionally or globally. Whereas studies such as those of Massey examine how place-specific contingencies – including gender and race relations – mediate economic outcomes within wider spatial structures of capitalism, others such as Harvey have been more interested to elaborate how the historical and geographical dynamics of capitalism might be charted as corrective responses to recurring ‘overaccumulation’ crises that are generated by limits immanent to it. There is continuity here with the Marxist economics of Henryk Grossman, Ernest Mandel and James O’Connor who, in varying formulations, hitch Marx’s theory of capitalist accumulation to the theory of crisis. (See also and Marxist geography; Radical geography.)

Harvey (1985b); Massey (1995).

Marxist geography The analysis of the geographical conditions, processes and outcomes of socio-economic systems, primarily capitalism, using the tools of Marxist theory. Marxist geography is significant both for its role in the evolution of the discipline and, more importantly, for its analytical claims about the world in which we live.

Marxism first became an important theoretical influence in geography in the late 1960s and early 1970s. Motivated by the radical politics of that era, many younger geographers grew dissatisfied with the then-dominant vision of geography as a technocratic, positivist science. They noted that: (i) a narrow focus on spatial patterns often left unexamined and unchallenged the social processes that produced the inequalities evident in those patterns; (ii) technically oriented, ostensibly neutral geographical techniques and analyses often served in practice to enable and perpetuate various relations of domination; and (iii) the ‘universal laws’ advanced by spatial analysts were often merely generalizations about industrialized Western societies. Marxist theory, by contrast, was dialectical, overtly political, focused on the analysis and remediation of exploitation and inequality, and internationalist. It therefore seemed to many an ideal theoretical foundation for a critical geography aimed at understanding and combating the production of unequal geographies. Radical geography framed in terms of Marxist theory grew quickly in the discipline: its arrival was signalled by the publication of the first issue of Antipode in 1969, and its theoretical architecture and points of departure from positivist spatial science were first laid out clearly in David Harvey’s Social justice and the city in 1973.

For much of the 1970s and 1980s, Marxist approaches were the dominant ones in critical human geography. Scholars working in this area developed increasingly comprehensive and detailed accounts of the geographical dynamics of capitalism, demonstrating persuasively both that Marxist theories of capitalism were incomplete without attention to spatial dynamics, and that identifiable capitalist processes and relations lay at the root of many issues of concern in contemporary human and environmental geography. Despite the fact that much of this work emerged from a critique of spatial science, some of it still bore the stamp of that theoretical tradition, inasmuch as much early Marxist geography sought to provide systematic, logical, deductive and generalizable accounts of the spatial processes and outcomes likely to result from endogenous dynamics understood as inherent to capitalism. David Harvey’s The limits to capital (1999 [1982]) remains the single most ambitious and significant work in this vein. In this and other works, Harvey sought to build upon Marx’s basic framework (see Marx, 1967 [187]) to analyse the ways in which capitalism uses and produces space and particular geographical relationships. For instance, ongoing
UNEVEN DEVELOPMENT at multiple SCALES was interpreted as the inevitable result of the tension between the need for capital to be fixed in place-bound material forms in order for production to occur on the one hand, and the imperative for it to remain liquid and mobile in the face of competition and shifting rates of profit in different places and sectors on the other. Similarly, Harvey explored how geographical relationships and strategies could be used to stave off CRISIS tendencies. Other work in this period was more historical in nature, examining the role that geographical relationships played in the origins of capitalism – whether those that concentrated large numbers of wage labourers in urban areas, thereby fostering class consciousness, or those that violently extracted and transferred labour and raw materials from colonies to industrializing core countries (e.g. Amin, 1976). Marxist geography (broadly conceived) also intersected productively with debates in THIRD WORLD Marxism in this period, leading to the development of explicitly geographical theorizations of the global capitalist economy, including WORLD SYSTEMS THEORY (Wallerstein, 1979) and DEPENDENCY THEORY (Frank, 1967), as well as critiques of the geographical imaginations underlying what often remained EUROCENTRIC conceptualizations of the global economy (Blaut, 1993). This brief review cannot do justice to the extent of Marxist geography in these decades, which also examined questions ranging from regional economic development strategies and industrial location decisions (e.g. Storper and Walker, 1989) to historical materialist interpretations of CULTURAL POLITICS (e.g. Harvey, 1989b). Marxist geographers’ engagement with the discipline’s NATURE–SOCIETY tradition proved highly fruitful as well: the intersection of Marxist theory, CULTURAL ECOLOGY and related work in the 1970s led directly to the burgeoning field now known as POLITICAL ECOLOGY (e.g. Watts, 1983a), while Neil Smith, focusing more on industrialized countries, made the strong claim that nature under capitalism was increasingly materially produced (1990). Such engagements sparked a line of work on the PRODUCTION OF NATURE that continues up to the present (e.g. Henderson, 1999), including debates about the primacy that such perspectives accord humans in general, and capitalist processes in particular, in the co-construction of nature. Much recent work in Marxist geography has focused less on structuralist MARXIST ECONOMICS, and sought instead to provide critical ETHNOGRAPHIES of capitalist societies (Postone, 1993; see, e.g., Chari, 2004; Wright, 2004), while at the same time re-evaluating core Marxist concepts, such as primitive accumulation, in light of contemporary geographies (e.g. Glassman, 2006).

Marxist geography itself soon became an object of critique, however, not least because of its very scope. Beginning in the early 1990s, much critical theory in geography and related fields moved strongly towards ‘POST-MARXIST’ theoretical frameworks that accept many basic elements of Marxist theory (e.g. the centrality of commodification and exploitation in capitalist societies) while criticizing much Marxism as fatally ‘modern’; that is, as an overly ambitious and totalizing meta-theory that seeks to explain nearly all human experiences, DIFFERENCES and POWER relations via a narrow, economic schema in which interests, conflicts, outcomes and even forms of consciousness can be deterministically read off from the position of an individual or group within relations of production (see Castree, 1999b). Whether such critiques rest upon a fair reading of all Marxist theory is debatable, but what is beyond question is that in recent years many critical geographers have found Marxism unhelpful, and sometimes even a hindrance, in attempts to analyse and combat multiple and intertwined forms of oppression. Instead, theoretical frameworks broadly characterizable as post-structuralist (see POST-STRUCTURALISM) have dominated critical geography in recent years, providing different entry points and tools with which to grapple with the problematics of GENDER, RACISM, SEXUALITY, POST-COLONIALISM and what might constitute ‘Left’ or radical politics in the contemporary era. Gibson-Graham (2006b [1996]), for instance, made a widely influential argument that Marxism often grants ‘capitalism’ far more coherence and power than it actually has, and that radical politics would be better pursued by seeking to identify and foster more modest alternatives to capitalist relations from the ground up, rather than by attempting to analyse and transform ‘capitalism’ as a global totality. Framings that pit these various theoretical frameworks against one another frequently rely upon quite reductive and static renderings of each; the most robust work in critical geography makes use of multiple theoretical perspectives in order to develop the fullest and most rigorous critical analyses possible. Nonetheless, Neil Smith’s observation (2005a, p. 897) that Marxism, ‘... may be the one oppositional politics which really has not been significantly rescripted into media fodder, integrated, in greater or lesser part co-opted, but always has to be opposed’, suggests at
the least Marxism’s enduring significance for critical geography.

**Suggested reading**

**Masculinism**

The tracing of connections between cultures of masculinity, knowledge and power. It is located within traditions of Western scientific rationality; in particular, the dualisms between mind and body, and subject and object, and the presumption that scientific knowledge can and should be objective and context free. Masculinist knowledge is criticized for claiming to be exhaustive or universal, while actually ignoring women’s existences or casting them within a gendered binary, framed from the perspective of men. Rose (1993) argues that geography is a masculinist discipline, and that masculinism determines conventions of what is deemed worthy of geographical investigation, fieldwork practice, theory development, writing and representation, as well as everyday academic life – from conduct in seminars to job searches and promotion. She identifies two masculinities (social and aesthetic) that frame this pervasive masculinism within the academic geographical imagination. (See also epistemology; feminist geographies; phallocentrism; post-structuralism.)

**Material culture**

Relationships between people and things, or, more formally put, the expression and negotiation of cultural, political and economic relationships via the material world of objects. Appadurai’s (1986) noted text in this area supplies a further shorthand definition: The social life of things. Culture has often been conceived as an immaterial and disembodied entity, composed of ideas, customs, knowledges and shared beliefs and values. One task for material culture studies – today an interdisciplinary venture, bringing together researchers from human geography, archaeology, anthropology, sociology and cultural and social theory – has been to examine how cultural beliefs and values gain permanence, power and significance through being given material form and expression in buildings, artefacts, commodities, visual symbols, displays, rituals and so on. Beyond this, however, writers in this area have also increasingly been concerned to think through the inherent materiality of culture itself. This has involved attending to the question of how cultural values are materially produced and circulated. It has further involved rethinking the categories of ‘culture’ and ‘materiality’ themselves.

The origins of material culture studies are complex. Traditionally, archaeology and anthropology have been the disciplines most clearly associated with the study of material forms of culture. Anthropology takes a realm of recovered material objects as the basis from which it seeks to reconstruct past cultures. Equally, anthropology places emphasis upon the importance of material forms and processes – objects, clothes, buildings – in the formation and communication of distinctive cultures and subcultures. However, contemporary material culture studies also draws inspiration from semiotic and interpretative analyses of the significance of particular commodity forms under capitalism. In such analyses (e.g. Roland Barthes’ 1957 Mythologies), cultural objects such as cars, wine and washing powders are understood as texts which are authored (or produced) and read (consumed) in various ways, and this is viewed as a process in which particular hegemonic or ideological cultural meanings are communicated and reproduced.

The study of commodities and their use and consumption has continued to be a mainstay of material culture studies (e.g. Miller, 1997), and this has further been one of the most important ways in which human geographers have contributed to and interacted with this field (e.g. Jackson, 1999). Over the past ten years, studies of the materiality of cultures and commodities have indeed flourished in human geography. In part, this has been framed in terms of an agenda seeking to ‘re-materialize’ human geographies (Jackson, 2000), in the wake of a cultural turn which, it is argued, placed undue emphasis upon the determining role vis-à-vis cultural practice of imaginative geographies of texts and images. This renewed geographical empiricism takes shape through studies following material objects within circuits of capital and commodity chains (e.g. Cook, 2004), and through studies focused upon the physical materialities of particular spaces and practices. At the same time, work drawing inspiration from actor-network theory and new materialisms has aimed to overcome a traditional duality in which matter is viewed as dead and inanimate, and can only be given meaning and form via the conduits of human thought and discourse. Writing in this area (e.g. Anderson and Tolia-Kelly, 2004) has been explicitly concerned to rethink the epistemological status of material objects, and has sought to develop languages and methods.
through which the agency and, it is argued, inherent ‘liveliness’ of the material world might be addressed.

**materialism** The history of materialism as a keyword in Western philosophy can be traced back to the Early Atomists in Greek thought, particularly Democritus, and thereon in the writings of Epicurus and Lucretius. Materialism has multiple strands, more-or-less mechanistic and more-or-less sensationalist. What each shares is the metaphysical claim that the nature, constitution and structure of reality are physical. Materialism is typically contrasted to various forms of _spiritualism_ or otherworldly existence (such as belief in God or supernatural beings), or _idealism_ – that is to say, a metaphysics that privileges mental entities – in other words, minds and their states – over physical entities. Of course, dualist metaphysics that admit as ‘real’ both physical and mental entities are also possible.

The Italian philologist Sebastiano Timpanaro provides one of the most forthright definitions of materialism on record. In his monograph _On materialism_, he writes:

> By materialism we understand above all acknowledgement of the priority of nature over ‘mind’, or if you like, of the physical level over the biological level, and of the biological level over the socio-economic and cultural level; both in the sense of chronological priority . . . and in the sense of the conditioning which nature still exercises on man and will continue to exercise for the foreseeable future. Cognitively, therefore, the materialist maintains that experience cannot be reduced either to a production of reality by a subject . . . or to a reciprocal implication of subject and object. (1976, p. 34)

Few would disagree that the physical world precedes life and consciousness, and that other life forms precede the human. But to contend that _nature_ is a self-evident or even autonomous domain that unilaterally conditions ‘man’ is problematic. As Raymond Williams (2005b [1980]) notes, Timpanaro’s separation of nature and human willfully ignores the fact that the materials that comprise nature are extrinsic and intrinsic to human beings. Additionally, a diverse literature on the production of nature within fields such as agrarian studies, Marxist geography, and science and technology studies (see science/science studies) – armed with a retinue of concepts such as ‘social nature’, ‘cyborg’, ‘techno-natures’ and ‘posthumanism’ (See _posthumanism_) – demolishes the notion of an independent nature.

What, then, binds materialism in its various forms – historical, dialectical, linguistic, cultural and _postmodern_? First, there is a rejection of spiritualism and idealism (indeed, radical materialists would contend that the dichotomy between idealism and materialism is itself an artefact of idealism); second, there is an emphasis on the social effects of an object- or material-world that is at least partly autonomous of humans; and, third, there is a commitment to forms of explanation that are attentive to the specific properties of materials as they influence – in often unpredictable ways – various sorts of interactions between human and non-human bodies. A specifically Marxist materialism might additionally assert that materialism is ultimately about how a mode of production constitutes matter (nature, human bodies, language) through social labour – which then carries the implication that any being is a historical and political fabrication.

**mean information field (m.i.f.)** The representation of a distance-decay relationship by a rectangular spatial grid, used in Torsten Hägerstrand’s (1916–2004) classic studies of migration and diffusion (see Hägerstrand, 1967). The m.i.f. was used in simulation models, in which the central square in a 5 × 5 grid represented a migrant’s origin, and the probabilities in the other 24 squares indicated the likelihood of them being the destination: the probabilities were either obtained from empirical analyses of migration patterns or pre-defined arbitrarily. Running the model many times generated an average pattern of the likely population distribution following a period of migration or the spread of an innovation – such as a new practice or a disease. (See also agent-based modelling.)

**measurement** A classification of data types, the characteristics of which are important in determining what quantitative analytical procedures can be deployed. Four levels are generally recognized:

- **Nominal** – each individual is allocated to one selected from an exclusive list of categories;
• *ordinal* – each individual is allocated to one selected from an exclusive list of rank-ordered categories;
• *interval* – in which individuals are assessed on a continuous quantitative scale; and
• *ratio* – in which the values on a quantitative scale can be relatively evaluated.

Thus, for example, 10 million people live in either Birmingham (UK) or London – which is a nominal allocation; London is bigger than Birmingham, which is ordinal; London has 9 million residents and Birmingham 1 million, which is interval; and London is nine times larger than Birmingham, which is ratio. Data from all forms of measurement can be analysed quantitatively, but different procedures are applied to different measurement types (cf. *CATEGORICAL DATA ANALYSIS; GENERAL LINEAR MODEL; REGRESSION*).

**MEDIA**

**media** Cultural technologies for the communication and circulation of ideas, information, and meaning. These are usually taken to include various mass communication media such as books, newspapers, radio, television, film and now various forms of ‘new media’.

In the past two decades, research on media-related topics has flourished in HUMAN GEOGRAPHY, without adding up to a theoretically or methodologically coherent agenda for media research. In CULTURAL GEOGRAPHY, media texts are often taken as a resource for analysing various forms of REPRESENTATION (of LANDSCAPES, PLACES, IDENTITIES, CITIES etc.). In ECONOMIC GEOGRAPHY, there is also a burgeoning literature on media production, distribution and consumption, given a further boost by the growth of digital media economies and culture industries. Nevertheless, the inherent SPATIALITY of media processes has attracted surprisingly little attention from geographers. Early work by Pred (1973) reconstructed the geographies of pre-telegraphic information circulation through newspapers in the USA in suggestive ways, but his main focus was on using these DIFFUSION processes to recover the emerging system of interdependencies between cities, rather than providing a close reading of the media reports themselves. More recent work in human geography has focused on the forms of social interaction that different media help to constitute (Adams, 1998). But in the main it is scholars working outside GEOGRAPHY who have provided most insight into the spatialities of media and communications. Thompson (1995) provides the clearest articulation of the study of media with the central concerns of SOCIAL THEORY, and in the process develops an analysis of the spatial and temporal constitution of social relations and institutions. He argues that different media and communications practices uncouple time and space, enabling the transmission of symbolic forms over time and space without physical transportation of objects; and they thereby enable new forms of simultaneous co-presence between spatially and temporally distanced subjects and contexts (see also TIME–SPACE DISTANCINATION). This type of analysis implies thinking of ‘media’ as a process of mediation operating ‘wherever human beings congregate both in real and in virtual space, where they communicate, where they seek to persuade, inform, entertain, educate, where they seek in a multitude of ways, and with varying degrees of success, to connect one to the other’ (Silverstone, 1999, p. 4).

As in other disciplines, media research in geography is prone to overestimate the causal power of media practices, and to make functionalist assumptions about the degree to which SOCIAL FORMATIONS are held together by the mass-mediated circulation of values over integrated political, economic and cultural territories (see FUNCTIONALISM). There is a tendency to assume that SUBJECTIVITY is media-dependent, and to presume that either the content of media texts or the patterns of ownership and control of media production and distribution are highly determinate in shaping patterns of belief, knowledge and practice. Media research in geography could benefit from taking seriously Garnham’s (2000, p. 5) claim that ‘the central question underlying all debates about media and how we study them concerns the way in which and the extent to which humans learn and thus how through time identities are formed and actions motivated’. Combining Garnham’s question of whether and how people learn through their engagements with media practices with Silverstone’s idea of media as processes of mediation points towards a more coherent agenda for media research: one that investigates how the spatio-temporal organization of media practices helps to distribute different possibilities of agency and communicative competency (Coulardy, 2006) (a project that also bears directly on recent discussions of PUBLIC GEOGRAPHIES, since a crucial question concerns precisely how publics are produced).

**Suggested reading**

Barnett (2003); Couldry and McCarthy (2004).
medical geography  A concern for ‘medical geography’ has been around for centuries, since Hippocrates, the Ancient Greek scholar associated with the origins of modern medicine, stated the importance of ‘airs, waters, places’ as an influence on human health, achievements and history. Such an environmental perspective has prevailed in many situations over the centuries, supplemented on occasion by a spatial perspective, and nowhere more obviously than in the celebrated case of Dr John Snow in mid-nineteenth-century London. Snow ascertained from empirical observations on the spatial distribution of cholera outbreaks something about the causal factors, contaminated water from a particular pump, within the transmission of this malaise. It is easy to detect the deep historical roots of medical geography, then, as a particular way of connecting many dimensions of human ill-health to a variety of environmental preconditions through the analysis of spatial patterns (revealing something about causes or vectors of transmission).

In more recent times, formalized in the First Report of the Commission on Medical Geography to the IGU (May, 1952), a sub-discipline of medical geography has arisen within academic geography and on the fringes of medical and related sciences. Prompted by contributions by the likes of May (1958) and Stamp (1964), the sub-discipline flourished, becoming the basis for research groups organized nationally (e.g. the AAG Medical Geography Speciality Group; the CAG Health and Health Care Study Group; the RGS–IBG Geography of Health Research Group) and with an international profile through the IGU Commission on Health and the Environment, International Medical Geography Symposia held since the 1980s, its own specialist journal Health and Place (founded 1995) and enduring prominence in the leading interdisciplinary journal Social Science and Medicine. Periodic worries have plagued the identity of the sub-discipline, however, with some objecting about too close a link with the concepts and practices of Western biomedicine, thus failing to take seriously alternative and ethno medicines rooted in quite other personnel, practices and places (Gesler and Kearns, 2002). Some (esp. Kearns, 1993; cf. Mayer and Meade, 1994) have speculated about the need for a broader characterization of the field as health geography or even ‘post-medical geography’, where health is defined as more than just the medically ascribed absence of ill health and health care as more than conventionally designated ‘medical’ interventions (Gesler and Kearns, 2002, p. 9; Parr, 2002: see HEALTH AND HEALTH CARE). The conceptual borrowings and methodological practices of the sub-discipline have also varied through time, with an empiricist and positivist stream deploying quantitative, modelling and GIS techniques being gradually supplemented – and on occasion challenged – by a diversity of approaches derived from Marxian political economy, humanism, post-structuralism, feminism and queer theory (Litva and Eyles, 1995; Philo, 1996; Milligan, 2001, Ch. 9; Parr, 2002).

It is often suggested that medical geography splits into the ‘twin streams’ of ‘geographical epidemiology’ and ‘health systems planning’ (Mayer, 1982), or ‘geography of disease/ill-health’ and ‘geography of health care’ (Litva and Eyles, 1995); although Gesler and Kearns (2002, p. 8) respond that these streams ‘have increasingly merged and . . . become more like a braided river’. One broad trajectory – connecting with population geography’s interest in mortality and morbidity – has studied geographical variations in ill-health at a range of scales from the global to the local, examining many different manifestations of ill-health for evidence of clear patterns in maps of prevalence and impact. Initially the interest here was disease, with the earliest studies concentrating on the obvious ecologies of diseases such as malaria in tropical settings (Pelzer, 1957, pp. 335–43: with links back to the colonial origins of geography), but with subsequent studies soon considering all parts of the globe (Howe, 1977). The ‘natural’ environment, in all of its climatic, topographic, fluvial, pedological and vegetative complexity, was inspected for its correlations with different diseases – chiefly those known to be infectious (tuberculosis, smallpox, influenza, HIV–AIDS), but also those with less certain aetiologies (the cancers, heart conditions, bone and nervous disorders) – creating an approach to medical geography readily positioned within the orbit of tracing human–environment relations (May, 1958; Learmouth, 1988; Meade and Erickson, 2000; Curtis, 2004, Ch. 6). An offshoot here shifted to a more narrowly conceived spatial epidemiology, building from basic mapwork to more advanced spatial–statistical techniques modelling the time–space diffusion of contagious illnesses (specifically influenza and HIV–AIDS) from person to person, place to place and through settlement hierarchies (Gould, 1993; Cliff, Haggett and Smallman-Raynor, 2004: for a rather different/critical take, see Brown, 1995 – and disease, diffusion of). Human
movements obviously shape such diffusion patterns, and some time ago Maegraith (1969) mused on what ‘jet age medical geography’, speeded up by the pace of worldwide travel and migration, might eventually look like.

This first stream of medical geography has been complicated by a concern with facets of ill-health for which the metaphor of disease is arguably less relevant, things such as malnutrition, obesity and stress, and extending to the vexed domain of ‘mental illness’ (as in Giggs, 1973, recognized as a classic of medical geography: see disability). Aspects of the social environment have also begun to feature, calling attention to phenomena such as employment, income, housing quality, lifestyle issues and related factors that predispose the ill-health of (certain) peoples in (certain) places, and demanding that medical geography foster dialogues with the likes of social geography, urban geography and other sub-disciplinary geographies (a decisive point made by Hunter, 1974; also Mayer and Meade, 1994). Additionally, as Dorn and Laws (1994, p. 107) underline, it becomes important to register the human body as more than just a host to some lesion or pathology waiting to be ‘discovered’ by the medical practitioner, and thus to recognize the variability of the human body, complete with differing material circumstances and cultural ascriptions bound up with its particular place in socio-spatial hierarchies of difference (Dear, Wilton, Gaber and Takahashi, 1997). Variable configurations of the body, marked by class, ethnicity, gender, ageing, sexuality, being a traveller or a refugee and so on (as discussed by Curtis, 2004, chs 3 and 4; see also Gesler and Kearns, 2002, Ch. 6), explain the greater or lesser likelihood of (certain) population cohorts in (certain) places ‘getting sick’, being interpreted as ‘sick’ and in need of assistance or avoidance, or as themselves being the possible sources of ‘sickness’ in others (as happened with the Chinese in nineteenth-century San Francisco: Craddock, 2000a). The emerging picture hence becomes less the hypothesized causal relations between easy-to-define environments, stable resident populations and their ill-health indicators, maybe cross-cut by the migrations of people bearing diseases, and more a mosaic of ‘health inequalities’ traced out across diverse, multiple and fluid bodies and places, wherein ecological influences enter into entangled admixtures alongside ones more obviously social, cultural, economic and political in origin (Curtis, 2004: echoing Eyles and Wood, 1983; Jones and Moon, 1987; Gesler and Kearns, 2002). Further challenges are posed by Smith and Easterlow (2005) when critiquing the ‘strange geographies’ of health inequalities research that emphasize how places determine (variable resilience to) death and disease, but neglect how such placed ill-health is itself bound into a more systematic operation of ‘health discrimination’—notably within labour and housing markets—fundamental to ‘the structuring of society and space’ (a thoroughly compositional matter, not a mere contextual effect).

The second stream of medical geography, concerned with health care as linked into health systems and planning, appeared in the 1960s when researchers began to study the spatial distributions of medical facilities. Questions were asked about spatial regularities in the locating of both hospitals of various kinds (Mayhew, 1986) and surgeries run by GPs, dentists and other primary service-providers (Curtis, 2004, 133–43), as linked to the accessibility and utilization of such facilities (Joseph and Phillips, 1984), and spatial mismatches were identified between provision and demand as a potential input to the more efficient spatial planning (location-allocation modelling) of healthcare systems (Clark, 1984). More recently, it has been argued that the basic geometries of health care cannot be explained solely by the principles advanced in spatial science but, rather, by recognizing the competing pressures on health managers in choosing where to locate facilities which arise from a wider socio-economic landscape that is itself unevenly constituted at a range of spatial scales (Mohan, 2002). Beyond such decisions, moreover, researchers have explored the political economy of health care, whether delivered by the welfare state (a public sector supposedly guaranteeing equality of access to all), an emerging shadow state (comprising voluntary-sector involvement) or an increasingly neo-liberal state in which all actors are compelled to pursue private-sector principles, entering or creating markets (internal or otherwise) to ensure competition and efficiency gains, and aiming at deregulation (even as legal–administrative demands are continually reinserted). More baldly, ‘there has been explicit recognition by health geographers of the underlying social forces that create inequalities, often expressed in terms of the impact of the capitalist economic system on health care provision’ (Gesler and Kearns, 2002, p. 51; see also Jones and Moon, 1987). Part
of this story has also been the growing commodification of health care, turning it into something that ‘customers’ elect to ‘consume’, quite likely using their (or others’) capital in the process, not a bundle of resources available to them as matter of right. The ‘selling’ of medical facilities, loosely equivalent to the marketing of places discussed by urban geographers, has become a sub-theme in the ongoing research of Kearns and co-workers (Kearns and Barnett, 1999; Curtis, 2004, pp. 125–33).

On a different but related tack, researchers have explored more cultural aspects of health care (Gesler, 1991; Kearns and Gesler, 1998; Gesler and Kearns, 2002), prompting enquiries into various cultural influences – the ‘thought-worlds’ of given societies, as well as everything from buried IDEOLOGIES through to the discursive scripting of health policies – that play out in the geographies of health care. Attention is paid to how agendas of power, control, medical authority and fiscal efficacy translate into the form, content and spaces of medical facilities, helping to explain location patterns (within overall systems), environmental associations (of particular facilities) and even architectures, decorations and layouts (of, say, hospital wards). At the latter, distinctly human scale, focus alights on the embodied relations between the ‘medics’ and the ‘medicalized’, and on how such relations are shaped by and performed across an array of in- and out-patient spaces of treatment, illuminating how both the power of the former is extended and the possible agency (maybe RESISTANCE) of the latter is expressed. This also means taking seriously the grounded experiences of the people involved, establishing how they perceive, feel about and understand what is occurring within spaces of health care, and recognizing the tensions that can fragment professional and lay judgements about what makes the best kind of ‘place’ for the delivery of the health care required (Milligan, 2001). Tellingly, this research strand begins to press at the limits of what is conventionally meant by ‘health care’, and has started to consider more ambiguous landscapes of health care – what Gesler (1992) has termed ‘therapeutic landscapes’ – wherein all manner of phenomena (mountains and springs, streets and malls) can be significant in how they promote or undermine senses of healthful well-being for those who access them. A further elaboration is work on health practices that possess an awkward relationship to Western biomedicine – that is, complementary and alter-native medicines, as well as the diverse forms of psychotherapy and counselling – which then suggests a still more inclusive interest in ‘geographies of care’ (Conradson, 2003a) wherein the overtly medical element is largely left behind (and a large step is taken towards that post-medical geography speculated about by Kearns, 1993).

megacities Very large, high-density urban centres, usually defined as those with populations exceeding 5 million. The International Geographical Union MegaCity Task Force (http://www.megacities.nl/) identified only four such centres in the 1950s, but 28 in 1985 and 39 in 2000: it estimates that there will be 60 by 2015. Most of these are in the ‘developing world’ (especially East and South Asia and LATIN AMERICA), are growing extremely rapidly, and face major problems of INFRASTRUCTURE provision and social inequalities.

Suggested reading

megalopolis A Greek word (combining those for ‘great’ and ‘city’) coined by Patrick Geddes and adopted by Jean Gottmann (1915–94: see Gottmann, 1964) to describe the discontinuous urban complex of the USA’s northeastern seaboard. It was also used some decades before by Lewis Mumford (1895–1988): to him, megalopolis was the end-state in the process of URBANIZATION, in which giant, fragmented cities become dysfunctional, whereas Gottmann deployed it as a descriptive label for extensive urban SPRAWL.

Suggested reading

memory An inherently geographical activity: PLACES store and evoke personal and collective memories, memories emerge as bodily experiences of being in and moving through SPACE, and memories shape IMAGINATIVE GEOGRAPHIES and material geographies of HOME, NEIGHBOURHOOD, CITY, NATION and EMPIRE. HUMAN GEOGRAPHY includes an important body of work on the role of the built landscape – museums, monuments, artefacts, heritage sites – in creating a sense of a common identity through memory, on how
collective memories are made material in the landscape, and the practices of memory-making through performances and rituals of remembrance. There is also a substantial literature on HERITAGE entrepreneurship as a marketable good (see also POSTMODERNISM).

Maurice Halbwachs’ book On collective memory (1992 [1941]) was an important early text theorizing memory as simultaneously social and spatial (as opposed to highly individualized and purely psychological) (Hebbert, 2005). Activities enhancing remembrance of a collective past, including commemorative rituals, story-telling, place naming and the accumulation and display of relics, trigger a social memory that solidifies a common shared identity. Halbwachs emphasized the importance of anchoring these memories in spatial imagery and physical artefacts, arguing that social memory endures best when there is a ‘double focus – a physical object, a material reality such as a statue . . . and also a symbol, or something of spiritual significance, something shared by the group that adheres to and is superimposed upon this physical reality’ (1992 [1941], p. 204).

This focus on the social constitution and context of memory informed French historian Pierre Nora’s (1997) influential project, which traced the development of French national identity through the analysis of a variety of ‘lieux de mémoires’, or sites of memory (see also NATIONALISM). Nora (1989, p. 9) argued that with the demise of peasant societies, ‘true memory’, available ‘in gestures and habits, in skills passed down by unspoken traditions, in the body’s inherent self-knowledge, in unstudied reflexes and ingrained memories’, has been replaced by ‘modern memory’ that is self-conscious, historical and archival. In modern society, we ‘must deliberately create archives, maintain anniversaries, organize celebrations because such activities no longer naturally occur’ (1989, p. 12). In short, the primordial memory of peasant societies embedded in milieux de mémoires (environments of memory) has been substituted by much more self-consciously created lieux de mémoires. The production of these lieux, or sites, has been a result of the transformations wrought by MODERNITY, including GLOBALIZATION, the rise of mass MEDIA and the institutionalization of a professional discipline of history. While Nora’s distinction between true and modern memory may be overwrought, in the 1980s his work spawned widespread interest in memory and place throughout the HUMANITIES and social sciences, and it continues to provide the impetus for a vast array of studies of different types of memory spaces (Legg, 2005).

The dominance of the NATION-STATE in framing memory has been the focus of much research on MONUMENTS and memorials. Because memory is always shadowed by forgetting, is vulnerable to manipulation and has a capacity to facilitate (or coerce) social cohesion, what is remembered and forgotten in national memory both reflects POWER relations and is of political consequence. Elite and dominant memory is typically mobilized by the powerful in the cultivation of a national imaginary, through monuments, memorials, public ritual, architectural and urban design, and through the erasure of previous PLACE NAMES or settlements of the dispossessed. However, human geographers have regularly noted the contested nature of meaning surrounding even official symbolic sites, and the production and consumption of such sites often involve CONFLICT (Till, 2001, 2005; Foote, 2003). They are neither uniformly designed nor read (and SPACE is significant in the construction of that meaning; Johnson, 2005). Nor do elites inevitably have a hold on LANDSCAPE production. Burk (forthcoming) describes the creation by grassroots groups in Vancouver of monuments to memorialize VIOLENCE against women. Recognizing the ‘power of place’ to repair cultural amnesia and nurture a more inclusive public memory, Hayden (1997) details a series of commemorative projects that concretize long histories of settlement of African American, Latina and Asian American families in downtown Los Angeles. Alderman (2003, p. 171) has examined how African Americans struggled to control and determine the scale of streets in which Martin Luther King Jr. would be remembered and thus the SCALE at which his memory would find public expression. He notes that the scale of memory was ‘open to redefinition not only by opponents to his political/social philosophy but also people who unquestionably embraced and benefited from this philosophy’.

Memory cannot be dictated, and popular memory can be an important vehicle through which dominant, official renditions of the past and present are resisted by mobilizing groups to create subaltern and counter-memories, and alternative futures (Legg, 2005). Shared memories of loss and longing for land may form the basis for collective claims to rights or reparation: Kosek (2004) argues that shared memories of dispossession from land by Mexicans living in northern New Mexico
are what make the Hispanic community in this region of the USA cohere as a social and political force. The same could be argued for Palestinians or, in Canada, First Nations groups. In diasporic and post-colonial contexts – in which memory is threatened by both nostalgia and coerced assimilation – ‘cultural memory offers promise of epistemological grounding’, though not necessarily within a singular national identity (Sugg, 2003, p. 469; see also diaspora; post-colonialism; transnationalism). Counter-memories may be assembled and transmitted through oral tradition, but also in less bureaucratised time-places: the body, domestic spaces (Blunt, 2003), neighbourhoods or ‘temporal re-territorializations’ of formal spaces (such as carnivals, festivals or rallies; Legg, 2005).

The memory projects of marginalized groups may bear the traces of trauma, such that the possibilities of memory are altered. With traumatic recall, events remain in the vivid present, resisting integration through narrativization. Though the state often incorporates violent or tragic events into a linear narrative of national redemption and overcoming, what Edkins (2003) calls ‘trauma time’ works differently, and its repetitive disruptive quality can reveal the violent foundations of sovereign power. Trauma thus has a relation not just to time but also space and geography; for instance, to narrations and experiences of nation and persistent claims to homeland. Sugg (2003) draws on Hirsch’s concept of post-memory to understand the ‘suspended migration’ of second-generation Cuban Americans: children of exiled parents may inherit the collective cultural trauma of their parents and remember their parents’ stories of exile as their own within a dynamic of longing and return. Alternatively, memorializing trauma in the landscape may constitute a witnessing public, setting in motion an emerging narrative (and a potential release from traumatic recall; Burk, forthcoming).

The recent tendency has been to expand the scope of memory studies by considering the role of performance and bodily and non-bodily practices in the making of memorial landscapes (Hoelscher, 2003), by examining the wider production of social memory beyond demarcated sites of monuments and memorials, and by considering the landscape implications of the memories of animals or other than human beings (Lorimer, 2006).

mental maps/cognitive maps Perhaps the best-known research outcome from behavioural geography was the retrieval of the imagined or mental maps widespread in the popular knowledge of places, mental constructs that were seen as intervening between geographical settings and human action. An early study was the simple sketch mapping of urban areas from memory supervised by Kevin Lynch in the pursuit of good urban design, which permitted an image of the city to be constructed, revealing districts of knowledge and ignorance, and the role of such remembered features as nodes, edges and landmarks in establishing urban legibility. Behavioural geographers, including Roger Downs and David Stea (1973), in contrast referred to cognitive maps, which they associated with the spatial tasks of orientation and way-finding. More formal and widely replicated were the experiments with paper and pencil tests conducted by Peter Gould and his students (Gould and White, 1993 [1974]), which were intended not so much to identify place knowledge and place ignorance but, rather, to establish a surface of place preferences. From surveys in several countries, mental maps were constructed that revealed both a national preference surface and also a local surface of desirability for a home area. Subsequent work sought to establish the developmental growth of maps among children of increasing age, and examined linkages between geographical preference surfaces and future residential choice and migration propensities (Gould and White, 1993 [1974]).

Mental maps were part of a broader movement in environmental perception, which in turn has elided into an interest in the representation and social construction of places in a variety of disciplines using less positivist methods and emphasizing social rather than psychological factors. Nonetheless, the older analytical methods continue to generate interesting results (Kitchin, 1994), even if with interdisciplinary dissemination the links with the original work are truncated or forgotten. So a current study of the role of the media in shaping the spatial surface of fear in Los Angeles (Matei and Ball-Rokeach, 2005), contains the key words mental maps, GIS and spatial effects, but omits any reference to Gould’s work, including his celebrated feature in Time magazine that included a map of the perceived fear of urban areas.

**metageography** ‘The set of spatial structures through which people order their knowledge of the world: the often unconscious frameworks that organize studies of history, sociology, anthropology, economics, political science, or even natural history’ (Lewis and Wigen, 1997, p. ix). The prefix ‘meta-’ implies an abstraction, a concept that in some sense goes beyond the term to which it implies, so by extension a metageography is a conceptual grid that structures how geographies are ordered. These grids are cultural constructions, and the emphasis Lewis and Wigen place on the fact that they are used more or less automatically and unconsciously, without critical reflection, connects the concept to that of a geographical imaginary. ‘Meta-’ can also imply an umbrella concept, and Lewis and Wigen focus their attention on the global scale and the conventional division of the world into continents. But the division of the globe into a mosaic of states is no less commonplace and taken-for-granted, against which Beaverstock, Smith and Taylor (2000) have proposed ‘a new metageography’: a global network of flows between cities. DG

**metaphor** For Aristotle, a metaphor ‘consists in giving the thing a name that belongs to something else’. Such practice is rampant in giving the thing a name that belongs to some other discipline: cities are plant biomes (CHICAGO SCHOOL), cultural landscapes are texts, economic localities are geological strata ‘layers of investment’ and non-renewable resources take on a life-cycle.

While pervasive, some writers have criticized metaphors for being ornamental and obfuscatory. Plato said that they make ‘trifle points seem important, and important points trifles’, while Thomas Hobbes believed that they ‘deceive others’, and in geography, Harvey (1967, p. 551) argued that they ‘hinder objective judgment’. In each of these cases, metaphor was attacked because it resulted in ambiguity: it is ‘a sort of extra happy trick with words’, as I.A. Richards (1936, p. 90) put it. More generally, such misgivings result from a particular view of language held by such critics: that language should be transparent, limpid and utterly dependable, all of which are undermined by metaphor.

Over the twentieth century there was an increasing recognition that language takes on none of those characteristics (see, in particular, DECONSTRUCTION) and, concomitantly, that metaphors are an indispensable part of both writing and theorizing. Metaphorical use comes in two shapes and sizes (Barnes and Curry, 1992).

**Small metaphors** that pepper individual writing and research are part of the very infrastructure of language construction, an omnipresent principle’ (Richards, 1936, p. 92). Mobilizing them requires skill and sensitivity, forming an important component of RHETORIC, the attempt to persuade others of the force of one’s argument by using tropes such as metaphor (Lakoff and Johnson, 2003 [1980]). Large metaphors, in contrast, structure entire research paradigms. Some, such as ‘organism’ or ‘mechanism’, are so deeply ingrained that they become ‘root metaphors’ (Pepper, 1942), whereas others are only temporary, mobilized for a particular use and then discarded. However long their durability, all large metaphors operate through a process of metaphorical re-description’ (Hesse, 1980); that is, transferring meanings and associations of one system in order to re-describe the explanation (the part of the explanation that does the explaining) of another system. An example is Isaac Newton’s metaphorical re-description of sound in terms of waves. Metaphorical re-description is ubiquitous, as well as ‘potentially revolutionary’ (Arib and Hesse, 1986). When Adam Smith coined the metaphor of the ‘invisible hand’ to describe the efficacy of the market, or when Marx said ‘workers have nothing to lose but their chains’, or when Bunge (1966, p. 27) asked, ‘Why cannot . . . concepts dealing with exotic and dioramic streams be applied to highways?’ revolutions, albeit of different kinds, were set in motion.

There has been sporadic interest in metaphor in GEOGRAPHY since the 1960s, when the proponents of SPATIAL SCIENCE first discussed the linkages between MODELS and metaphors (Haggett and Chorley, 1967). Later, those who advocated a HUMANISTIC GEOGRAPHY, such as Tuan (1978) and Livingstone and Harrison (1981b), were drawn to metaphors because of resonances with human creativity and meaning, twin planks of the larger project (see also HUMANITIES). Most recently, critical attention has come from geographers interested in EPISYSTEMOLOGY. Large metaphors sometimes carry unexamined intellectual freight, resulting in unintentional and sometimes contradictory meanings. They need to be unpacked, inspected critically for their coherence, consistency and compatibility. Doing so also means scrutinizing their historical and material origins. Metaphors require ‘worlding’ (Smith and Katz, 1993).

**methodological individualism** The view that social events must be explained by reducing them to individual actions, where, in turn, those actions are explained by reference to the intentions of individual actors. For the methodological individualist, all macro-scale social entities are ultimately decomposable to the acts and underlying intentions of individuals. Society, therefore, is a chimera, something that appears real, but which is not. As a perspective, methodological individualism is usefully contrasted with, on the one hand, approaches that accentuate the importance and reality of trans-individual social structures (as found, for example, in structural Marxism, a form of Marxism that trades on structuralism) and, on the other hand, approaches that deny the autonomy of individual human subjects altogether (as found, for example, within post-structuralism).

The term ‘methodological individualism’ was first systematically deployed by the German sociologist Max Weber, in his book *Economy and Society* (1968 [1922]). He was keen to argue that social collectivities such as firms or governments must be treated as solely the resultants . . . of the particular acts of individual persons, since these alone can be treated as agents in a course of subjectively understandable action (Weber, 1968 [1922], p. 13). Weber’s point was not to privilege individuals over social institutions, but to stress that understanding social phenomena should rest methodologically on action-based theory; that is, theory providing motivations for agents to act (in Weber’s theory, this turned on the methodological protocols of *Verstehen* (“understanding”) and ideal types).

In subsequent versions this point was lost, however, and methodological individualism was used to privilege the individual primarily for the purpose of disparaging especially Marx’s theory of historical materialism, which rested precisely on collective social entities. This impulse is found in Friedrich von Hayek’s and Karl Popper’s writings of the 1940s and 1950s, and then again in Jon Elster’s (1982b) work on analytical Marxism in the 1980s and 1990s. While there are differences among these three writers, they also have commonalities. First, Hayek and Elster, and perhaps Popper too through his model of psychological reductionism, adhered to a rational choice model of the individual derived from neoclassical economics: rationality was posited as the only action-based motivation for agents. Second, all three accepted that rational individuals represented ‘rock-bottom explanations’ of social phenomena (Watkins, 1957, p. 105).

Both the specific rational choice model and the more general notion of an individualist ‘rock-bottom’ explanation have been criticized: the underlying intentions of an act are not always known, and so it may be impossible to provide individual action-based accounts; non-individual based forms of explanation – for example, aggregate-statistical – can in some cases provide better explanations than ones resting on individual motivations; individuals in interaction with one another produce emergent effects irreducible to individual acts; and individuals are the consequence, not the cause, of social structures and institutions (‘methodological holism’).

Because of the association with the rationality postulate, in human geography methodological individualism was found most readily in economic geography, since it was most influenced by neoclassical economics, and it also reappears in regional science and the new economic geography. But the cultural turn and the turn to institutional economics have resulted in the strong assertion of the importance of social phenomena on their own terms, and hence a falling away of methodological individualism from the one sub-discipline where it had gained a foothold (Lee and Wills, 1997).

Heath (2005).

**methodology** The principles and assumptions underlying the choice of techniques for constructing and analysing data. Methodology should not be confused with ‘methods’: it is the conceptual rationale for which methods are used, and how. Methodology brings together and links the underlying philosophical and conceptual bases of a study with appropriate techniques. Good methodologies thus align the ontology of a study, how it conceives of the world, with its epistemology, how it claims to know things about the world. This is more than, though it includes, competently using one or more research ‘techniques’. This Dictionary, for instance, lists at least 11 groups of techniques and many more analytical and representational procedures for the data thus created. Methodology is a meta-level issue about fitting techniques to research questions, rather than simply learning a method.

A weak formulation of methodology as recounting how research was done was
inspired by the sciences and is often a hallmark of social science perspectives. This recounting of procedures offers a methodological transparency that is the hallmark of scientific studies in that it allows readers the chance to ‘disprove’ a study’s conclusions. Even beyond formally scientific studies, transparency is often still advocated as a way of ensuring rigour and validity across a variety of approaches. Baxter and Eyles (1997) suggest adapting ideas from Lincoln and Guba so that for all methods, including qualitative methods, the following have to be shown:

- credibility of the account (i.e. authenticated representation of what actually occurred);
- transferability of the material (i.e. making what occurred intelligible to the audience);
- dependability of the interpretation (i.e. that it is not illogical, or how partisan it is); and
- confirmability of the study (i.e. the ability to audit the process that made it through personal reflection, audit processes or opportunities for informants to reply).

The emphasis here is on the clear statement of procedures undertaken, the techniques and steps of analysis as a means to enable the reader to examine the process leading to the results and conclusions. Traditions of transparency are variable across even sub-disciplinary fields where, for instance, in a comparison of the Journal of International Business Studies and Economic Geography, around 80 per cent of articles in the former had formal sections on methodology and the collection of data, while in the latter only 30 per cent or less had such sections (Poon, 2007). A degree of transparency might also be intended to enable a reflexive account that positions the research process, and allows the reader to see the contingent and situated production of knowledge. This may in fact be aimed at undercutting notions of authoritative social science by demonstrating fallibility and the limits to knowledge, and may be inspired by approaches to research ethics that foreground the contributions of research participants. Thus feminist methodology stretches from design to dissemination of research, but must also consider the ‘relationships among people involved in the research process, the actual conduct of the research, and process through which the research comes to be undertaken and completed’ (Moss, 2002, p. 12).

A stronger definition of methodology points out the different ways in which these criteria of reliability reflect theoretical approaches. For example, sampling within extensive research would have to meet criteria of representativeness to support statistical analysis of the data, while within qualitative methods it might aim to capture a particular group’s perspective, where its validity depends on the quality of material derived from their positionality. In this case, methodology is about joining the stages in the research from underlying philosophy to research questions to techniques generating data to forms of analysis and presentation of the results.

A methodology thus involves considering how the specific techniques can be assembled and used to generate the sort of data that will enable an answer to the questions posed through a specific conceptual framework. There have been extensive arguments about whether specific conceptual frameworks demand specific methodological linkages and preclude some methods. For instance, feminist geography had a long debate over whether it required feminist methods, that sought to empower, give voice to women and treat them as ‘subjects’ who made knowledge, or whether it could use the quantitative methods that feminist theorists had often critiqued for treating people as objects of knowledge and using a detached masculinism in its logics. This debate has seen special issues of journals, such as the Professional Geographer in 1995, assessing whether a feminist methodology can include various techniques such as GIS.

If methodology is about assessing how to create material that will answer the conceptual questions in a study, the answer may well be to use multiple methods. Thus some parts or issues might be addressed via one method while others could be addressed by another. This is often called triangulation, named metaphorically after the surveying practice of taking bearings from different landmarks. Here, methodology is about combining methods to help validate each others’ findings and, optimistically, integrating different forms of data in the analysis (Knigge and Cope, 2006). On the other hand, it might be argued that the different techniques, with different ontologies, construct radically different versions of the world that cannot be brought into the same epistemological approach. How can, say, a social constructivist account be allied to modes of statistical inference that rely on realism or assumptions of objectivity? In
such a case, a methodology might be about holding tensions that show these gaps and differences to offer a ‘transgressive validity’ that problematizes or crystallizes the issues of reliability and truthfulness between methods, rather than integrating them or using one to corroborate the other (Guba and Lincoln, 2005). An exemplary account in geography is Nightingale (2003) on forest cover in Nepal, illustrating the partiality of and contradictions between both villagers’ oral histories and aerial photography.

Methodology is thus about organizing research practices in relation to concepts. There is no singular way of doing this; nor is methodology simply the application of methods. It involves thinking through the connections relating concepts, topics, information-gathering and representation, which will inevitably vary from project to project.

**metropolitan area** A general term for large urban settlements. Metropolitan districts were first defined by the US Bureau of the Census in 1910, by grouping together large central cities (i.e. administrative districts) with their contiguous suburbs into a single built-up area to be used for reporting data. Over time, with continued urbanization and urban sprawl, definitions changed and there is now a hierarchy of areas:

- **Metropolitan Statistical Areas (MSAs)** – groups of counties (or similar administrative units) with total populations exceeding 100,000, comprising a central city (with 50,000 + residents) and surrounding suburbs;
- **Consolidated Metropolitan Statistical Areas (CMSAs)** – larger units with populations exceeding 1,000,000; and
- **Primary Metropolitan Statistical Areas (PMSAs)** – separate components within CMSAs: the Detroit/Ann Arbor CMSA comprises the separate Detroit and Ann Arbor PMSAs, and the New York/New Jersey/Long Island CMSA contains ten separate PMSAs.

Analysts have also defined Metropolitan Labor Areas, which extend beyond the built-up areas to incorporate places from which at least 5 per cent of the workforce commutes to a metropolitan area.

Similar schemes (with terminological variations) have been defined by the census authorities to represent and report data for the urbanized areas in a large number of other countries.

**micropolis** A term introduced by Thomas (1989) and adopted by the US Bureau of the Census in 2003, referring to urban agglomerations with total populations between 10,000 and 49,999. Each micropolis comprises a number of separate but socially and economically integrated settlements (as measured by commuting patterns), one of which (the ‘core centre’) has a population of at least 10,000; for example, the separate settlements of Lebanon (CT), Hanover and Enfield (NH) and Norwich and Hartford (VT) in the Upper Connecticut Valley comprise a micropolis based on Hartford. Using 2001 census data, 578 separate micropoli were identified, containing about 10 per cent of the total US population. (See also metropolitan area.)

Heubusch (1997).

**microsimulation** Microsimulation operates at the ‘micro’ (not aggregate) scale, where the ‘units’ include the individual, household, firm or vehicles (International Microsimulation Association, www.microsimulation.org). These units and their socio-economic trajectories are modelled by assigning them data attributes that are altered over (simulated) time by a set of rules governing the system in which they exist. Changes may be deterministic (they must happen, given certain characteristics) or stochastic (see stochastic process: there is a probability that they might happen). In this way the impacts of, for example, government policies and economic decision-making can be modelled. There are links between microsimulation and geocomputation, especially cellular automata and agent-based modelling.

**Middle East, idea of** The term has its origins in European and eventually American
DISCOURSES of diplomacy, geopolitics and security, and in a more diffuse cultural register as imaginative geographies of a largely Arab ‘Orient’. The two cross-cut in complex ways, but they have their origins in Napoleon’s military occupation of Egypt in 1798 (see occupation, military), in some measure part of a plan to cut Britain’s lines of communication with India, and the bloody campaigns that he fought through the Levant. In invading Egypt, Cole (2007, p. 247) argues, ‘Bonaparte was inventing what we now call “the modern Middle East”,’ and ‘the similarities of the Corsican general’s rhetoric and tactics to those of later North Atlantic incursions into the region tell us about the persistent pathologies of enlightenment republics’. Said (2003 [1978]) locates the formation of a distinctly modern orientalism in the textual and visual appropriations of Egypt made for a European audience by the scientists, scholars and artists who accompanied the French troops.

French politicians and diplomats had described the Ottoman Empire as la Proche-Orient (‘the Near East’) from the end of the eighteenth century, and for most of the nineteenth century the ‘Eastern Question’ that concerned high politics in Europe was invariably an Ottoman one. But in the course of the nineteenth century civil servants in Britain’s India Office started to describe what was then Persia and its surrounding regions as ‘the Middle East’, and it was the geo-strategic relation to Britain’s Empire in India that gave the term its eventual currency. In 1902 an American naval officer, Alfred Thayer Mahan (1840–1914), in what proved to be an extraordinarily influential essay on ‘The Persian Gulf and International Relations’ (Mahan, 1902), argued that Britain’s control over its approaches to India via Suez and the Gulf (which is how he loosely defined ‘the Middle East’) was threatened by Russian advances in Central Asia and by the proposed construction of a rail link between Berlin and Baghdad; not surprisingly, he championed the importance of sea power, and recommended that the Middle East would ‘some day need its Malta as well as its Gibraltar’. The term was popularized by Valentine Chirol, who published a major series of articles in the Times, followed by a book under the title The Middle Eastern question, or some political problems of Indian defence (1903).

The ‘Middle East’ was envisioned as a security belt running from Persia through Mesopotamia and Afghanistan to Kashmir, Nepal and Tibet: as Scheffler (2003, p. 265) notes, an abstract space whose common denominator was a strategic location across the northern and western approaches to India.

The region was redefined after the First World War, the collapse of the Ottoman Empire and the attempt by the Great Powers to divide most of the spoils between them, but it retained its strategic inflection and gained new geo-economic significance as the importance of oil came to be recognized (at first, as the basis for naval supremacy). The European powers drew new lines on the map to create new states. In 1921, Churchill created a Middle East Department in the Colonial Office, whose area of responsibility was Iraq, Palestine, Transjordan and Aden; and during the Second World War Britain established a Middle East Command, whose area of responsibility spiralled out from Iran, Iraq, Palestine, Syria, Transjordan and the Arabian Peninsula to include Greece and Malta in the Mediterranean and Egypt, the Sudan and swathes of East Africa. After the war, the region was plunged back into conflict by the partition of Palestine, the foundation of the state of Israel in 1948 and the dispossession of hundreds of thousands of Palestinians. By then, Britain’s star was fading – a fact dramatically confirmed by the Suez Crisis of 1956 – and growing American geopolitical and geo-economic interest in the region, partly in response to the expanding Soviet sphere of influence during the cold war, was signalled by the US State Department’s focus on a Middle East that it now delimited as Egypt, Syria, Israel, Lebanon, Jordan, Iraq, Saudi Arabia, Kuwait, Bahrain and Qatar. This new regionalization was underwritten by financial support for area studies and Centers for Middle Eastern Studies at major American universities.

Europe and America continued to be exercised by the region throughout the second half of the twentieth century and on into the twenty-first, and its geopolitical construction as what Sidaway (1998) called an ‘arc of crisis’ spanned successive wars between Arab states and Israel, the Israeli occupation of Gaza and the West Bank after 1967, the unresolved Palestinian question and the intifada, chronic crises and civil wars in Lebanon, the Iraq–Iran War (1980–8), the Iraqi invasion of Kuwait and the first Gulf War (1990–1). A key US response to these crises was the formation of a unified combatant command in 1983, US Central Command (CENTCOM), to cover the “central” area of the globe between the European and Pacific Commands’ and which (in significant part) retraced the outlines of the former British Middle East Command.
Its importance was further increased by the terrorist attacks on the United States on 11 September 2001 and the US-led invasions of Afghanistan in 2001 and Iraq in 2003 (see Terrorism).

CENTCOM articulates a highly particular imaginative geography of the region (Morrissey, 2009), but the invasions of Afghanistan and Iraq were underwritten by, and also extended, a series of cultural formations that could be traced back through the long history of British and American interventions in the region to a deep-seated Orientalism (Gregory, 2004b). In doing so, they confirmed that the ‘Middle East’ is a profoundly ethnocentric construction, as Bernard Lewis (1999) once had it, ‘meaningless, colorless, shapeless, and for most of the world inaccurate’. This reached its nadir in portrayals such as this, from Fareed Zakaria, writing in Nieuwsweek soon after 9/11: ‘This is the land of suicide bombers, flag-burners and fiery mullahs.’ In one astonishing sentence, the various, vibrant cultures of the region were fixed and frozen into one diabolical landscape (Gregory, 2004b, p. 60). And yet this (in)sensibility captured the accumulated rhetorical effect of constructions of the Middle East with dismal fidelity. For the ‘Middle East’ as a concept has been constructed, both geopolitically and discursively, largely from the ‘outside’: and yet its problems and predicaments are almost always assigned solely to those on the ‘inside’. As Mamdani (2002) put it, within the optic of a Euro-American ethnocentrism, the world is divided into two, ‘so that one part makes culture and the other is a prisoner of culture’. DG

migrancy The state or condition of being a migrant; ‘migrancy’ generally emphasizes the cultural, social and political constructions and experiences of migrant groups and displaced people (cf. migration). Historically, the slow and discontinuous process of sedentarizing populations and fixing political borders and boundaries was often accompanied by a suspicion of those who remained constantly on the move. Thus, for example, the figure of the merchant forever travelling to fairs and distant markets occupied an ambiguous position within the territorializations of feudalism in much of medieval Europe, even though such movements provided essential functions for trans-regional economies. Mobility was often a privilege, to be sure, and it was threaded in to wider circuits of power and authority, so that it was (and remains) those who were homeless and forced to move (through disease or poverty, for example) who attracted the most suspicion and even hostility. Some social groups regarded migrancy as a cultural formation constitutive of their very identity: ‘travelling peoples’ such as the Roma (‘Gypsies’), the tramping artisans of nineteenth-century Britain (Southall, 1991) or the hobos of late nineteenth- and early twentieth-century America (DePastino, 2003).

Even though globalization and modernity are predicated on movement and depend on migration, these capacities are still subject to social discrimination. Under neo-liberal globalization, the world may be ‘flat’ for business travel and international tourism, but those who travel under other, no less legitimate, signs are subject to policing, restriction and even detention: the Roma continue to encounter social exclusion (Sibley, 1998; Bancroft, 2005) and groups such as asylum-seekers and refugees, and guest-workers in Europe, the Gulf, Asia and Canada, find their living conditions and civil rights circumscribed by their very migrancy. The suspicion of migrancy is shared by colonial and post-colonial states alike, whose governments often view migrant populations as threats to their ordering design and apparatus of control. Pastoralists and shifting cultivators were (and continue to be) seen by states as lesser producers whose activities thwart efficiency, erode environments, and undercut the positive externalities that putatively attach to private property and sedentary agriculture (see pastoralism). Lurking in these assessments is a sense that migrancy equates to vagabond conduct, an equation that is frequently sharpened through racialization: thus the Bedouin in Israel have been constructed by the Israeli government as inimical to the property and political regimes of the settler state, and, through their supposedly aberrant spatiality, left literally ‘out of place’ and ‘suspended in space’ (Shamir, 1996; Mair, 2008).

In counterpoint to these bleak assessments, however, and the unilinear teleology of a singular Western modernity that sustains some of them, Gidwani and Sivaramakrishnan (2003) have emphasized that the subject-positions produced through migrancy cannot be axiomatically reduced to passivity or victimhood and that, in particular circumstances, these mobilities – often marginalized in conventional accounts – may be vehicles for cultural and political assertion. To recover the
complex contours of MIGRANCY and the web of DIASPORIC populations thus requires both critical analyses of the institutions that frame and facilitate, entrap and exclude migrants, but also careful and intrinsically spatialized ETHNOGRAPHIES of the migrant condition.

migration The residential relocation of an individual, family or group from one place to another (see also MIGRANCY). It is distinct from TOURISM or other short-term visits that do not involve a change in residence. Geographers have been particularly interested in migration, since it is so clearly related to both the development of PLACES and the relationships between them (Skeldon, 1997; Black, 1998). According to the most recent figures, there are nearly 200 million migrants in the world, defined as people who are living outside their country of birth (Global Commission on International Migration, 2005). Traditionally, migration is classified according to four broad criteria: intra-national versus international; temporary versus permanent; forced versus voluntary; and legal versus illegal (Bailey, 2001; Castles and Miller, 2003). Within GEOGRAPHY and other social science disciplines, scholars tend to specialize according to these distinctions. For example, the field of intra-national migration (also known as MOBILITY) is generally distinct from that of international migration. Similarly, largely separate groups of researchers study forced migration, or the movement of REFUGEES and ASYLUM seekers, versus those who study migration arising from economic motivations. If nothing else, these categories reveal that migration is a complex phenomenon that can be generated by a number of processes. Just as there are many causes of migration, there are also many consequences. Recently, critical geographers and other progressive scholars have called these sharp distinctions into question, noting that most migrants take a variety of factors into account when making their decision to move (Bailey, 2001). While it may seem an obvious point, this is a crucial issue, since all of the systems that seek to regulate migration are based on the assumption that the causes of each individual movement are identifiable and discrete.

Ernest George Ravenstein is acknowledged as the first person to theorize migration and he introduced a number of 'laws' – in the 1880s – that he believed captured the most important processes involved (Grigg, 1977). For example, he stated that: the tendency for migration varies inversely with the distance between source and destination (i.e. there are far more short-distance moves than long-distance ones); the majority of migrants move in order to improve their economic circumstances; therefore migration is mainly directed to places of concentrated economic opportunity, particularly cities; migration accelerates when movement becomes easier (e.g. once TRANSPORTATION infrastructure is in place); women tend to move shorter distances than men; and migration in one direction eventually generates its opposite – movement in the opposite direction. These early generalizations are still seen as relevant and form the basis of the most prominent model of migration. The GRAVITY MODEL uses a simple mathematical equation to predict the amount of migration between any two places, which is projected as the product of the population size of the two places divided by the distance, squared, between them. More elaborate versions of the gravity model take more factors into consideration and are correspondingly more mathematically complex.

Migration theories today are dominated by three strands of thought. The first is a legacy of the Ravenstein approach, but informed by more recent economic theories. It posits that individuals migrate when it is in their economic interest, and will go to the place that maximizes their life-long earning potential. Meanwhile, governments create migration policies to attract the talents that they lack (cf. PUBLIC POLICY). The world is therefore seen as a kind of 'migration MARKET', much like the labour market, with rational actors and predictable outcomes (Borjas, 1989). Individuals with high levels of human capital (education and work experience) go to places that provide the highest wages for that group. Meanwhile, less-skilled individuals gravitate to countries with the least polarized wage rates and the most generous welfare policies. These types of migration are labelled, respectively, 'positive' versus 'negative selection'. There is also an emerging new economic theory of migration that considers families the basic unit of decision-making rather than individuals. According to this theory, families seek to enhance their survival through minimizing risk (as opposed to atomized individuals seeking to maximize their earnings), and therefore attempt to place individual family members in several countries at the same
time, providing multiple possibilities should life become difficult in any particular place (Massey, Arango, Hugo, Kouaouci, Pellegrino and Taylor, 1993). Economic theories of migration, old and new, are often used to generate predictions of the scale and direction of migration. For this reason, they are considered to be highly relevant by governments that are interested in regulating migration. Critics charge that these models make invalid assumptions (e.g. that individuals are fully informed about opportunity structures in other countries), and produce highly simplified results.

The second major strand of migration theory is based in the logic of world systems theory. According to this view, migration is generated by the expansion of the capitalist system throughout the world, which destabilizes traditional ways of life – both economically and environmentally – in an ever-expanding periphery (Black, 1998). People move because their livelihoods are compromised, especially when they also become captivated by the lure of high wages and consumer capitalism in affluent countries. However, affluent countries create barriers to migration in an effort to preserve their privilege. They therefore allow the selective admission of highly skilled individuals (such as trained medical professionals or high tech engineers) and relatively small numbers of individuals who are deemed to be unskilled, who are expected to accept jobs that are protected by professional associations or unions. Migration regulations are therefore implicated in a continuing process of development versus underdevelopment, both across societies and within them (Massey, Arango, Hugo, Kouaouci, Pellegrino and Taylor, 1993).

The third major body of theory emphasizes social aspects and is especially concerned with the relationship between social networks and migration. Individuals make migration decisions in the context of imperfect information that is shared across social networks, which often include people who have migrated (Tilly, 1990b; Weiner, 1995). Migrants tend to follow those who have gone before them, in a process that is called chain migration. This is a rational process, since new migrants benefit from the experiences of their predecessors. Newcomers are also assisted when they arrive in the destination country. As this process gains momentum, immigrant communities emerge and gradually build in-group sociocultural institutions. Frequently, these communities are geographically concentrated and may be seen by mainsteam society as ghettos, places that are both isolated from mainstream society and also disadvantaged – though there are important exceptions to this tendency (cf. underclass). The network approach to migration has led to three particularly powerful insights. First, chain migration leads to a process of cumulative causation; that is, each move helps build pathways that facilitate additional migration. Migration begets migration (Massey, Arango, Hugo, Kouaouci, Pellegrino and Taylor, 1993). Gradually, people in the source society become convinced that migration is 'normal' and even expected as a rite of passage. Second, social networks become stretched between source and destination societies, with people who are closely connected on both sides. Echoing the point first made by Ravenstein, people begin to move back and forth across these networks in a process of circular migration. Frequently, these moves are linked to significant lifecycle turning points, such as entering tertiary education, looking for work, raising a family and retirement. Moreover, information flows quickly across these stretched social networks, as people communicate on a regular basis and economic links also intensify. People in these transnational networks develop new, combinatorial identities that include elements of both source and destination societies, and are conscious of political and social developments in both societies (Vertovec, 1993; Levitt and Glick Schiller, 2004). Geographers have contributed significantly to understanding these forms of transnational behaviour and identity. Finally, scholars who study migration networks highlight the significant differences between men and women in all aspects of migration, including: the reasons for migration; migration pathways; and the consequences of migration for the individuals involved (Pessar, 1999; Silvey, 2006; Yeoh, 2006).
MILITARISM

All of these theories are much better equipped to understand voluntary migration, where people make choices about when to leave and where to go. Actually, the bulk of international migration is forced: people are compelled to leave their residence due to conflict, persecution, environmental degradation, natural disasters or development projects (Black, 1998; Hyndman, 2000). Certain types of forced migration are monitored and, to a degree, regulated by international agencies, particularly the United Nations High Commissioner for Refugees (UNHCR) and the International Organization for Migration. These organizations assist migrants by helping build and service refugee camps, facilitating repatriation when circumstances in conflict zones improve, and arranging resettlement in other countries in cases when conflict or persecution persists. In 2006, the UNHCR estimated that there were approximately 20 million ‘persons of concern’, or refugees, worldwide. The UNHCR and other agencies attempt to ensure that the principles of the 1951 UN Convention Relating to the Status of Refugees, and the 1967 UN Protocol Relating to the Status of Refugees are upheld. Note that other types of migration are mainly regulated by nation-states rather than international agencies. That is, nation-states generally have the right to decide who can enter their borders and on what terms (Castles and Miller, 2003). However, signatory states to the aforementioned UN Convention and Protocol are obligated to provide asylum to refugees.

Since the 1980s, researchers have sought to understand the ethical issues involved in migration. This sub-field tends to concentrate on three major issues. First, is migration a human right? That is, should individuals have the right to live where they choose (based on an individual rights perspective; Carens, 1987), or should states have the right to control their membership by selective admission policies (based on a collective rights perspective; Weiner, 1996)? Second, who should realize the rewards of migration and, conversely, pay the costs associated with it: the migrant, the destination society, or the source society (Castles and Miller, 2003)? Generally speaking, governments of countries that receive migrants create admission policies that are intended to secure the benefits of migration for their societies, and pay little attention to migrants and virtually none to source countries. For example, affluent countries frequently encourage highly trained medical personnel to immigrate without considering the difficulties involved for the migrants (in re-establishing their credentials) or for the consequences for source countries (which are losing scarce individuals who have typically been trained in public education systems). Third, what should be expected of migrants once they join a new society? Should they be required to assimilate or be encouraged to retain their cultural traditions? Each of these questions has generated vigorous debate in the scholarly and policy-oriented literatures.

militarism The extension of military influence into civilian political, social and cultural spheres. This is achieved through both the direct extension of the immediate influence of state militaries and the indirect influence of military agendas on political institutions, social norms and cultural values (see Woodward, 2005). In his farewell address to the nation in 1961, US President Dwight D. Eisenhower warned against the ‘acquisition of unwarranted influence’ by what he called ‘the military–industrial complex’: since then, the connections between militaries, defence industries and the global arms trade have become ever more intimate, but over the same period the multiple extensions of militarism have prompted many analysts to identify an even more extensive military–industrial–media–entertainment complex (MIME). Geographically, militarism is manifest in military control of place, space and landscape; military influence over civilian law enforcement and legal geographies, and the militarization of security; military research within universities and research and development organizations (for militarism in geography, see Barnes and Farish, 2006; Barnes, 2008b); and military themes in popular geopolitics, linked to the dissemination of distinctive imaginative geographies through films, novels, video games, web sites, and television drama and news (see, e.g., Power, 2007; Stahl, 2006, and Stahl's documentary film on the militarization of American popular culture, ‘Militainment Inc.’: description and trailer at http://www.freewebs.com/apocalyptic/militainmentinc.htm). In these various ways, militarism serves as an ideology that makes particular claims on notions of citizenship (Stahl, 2006; Cowen and Gilbert, 2008) and, not least through its appeals to particular
notions of masculinism, also legitimizes and even glorifies the pursuit of war. (See also military geography.)

**Military geography** The study of geographical activities of military activities and operations. Facilitating the military activities and operations of nation-states was central to the emergence of modern geography as a formal academic discipline. The enlistment of geography in the service of empire has become a commonplace of the history of geography (see geography, history of), and the foundation of the Royal Geographical Society in Britain in 1830, for example, was closely associated with the desire to formalize geographical knowledge to be put to work in the extension and management of the British Empire through exploration and survey, often closely connected with military personnel and military objectives, and through the conduct of military campaigns (Woodward, 2005). Some historians point to the Franco-Prussian War of 1870–1 as a major spur to the institutionalization of the discipline in Europe: the unexpected victory of the Prussian army was attributed, in part, to its superior training in geography. Across the Atlantic, a sub-discipline identified as military geography could trace its origins to the establishment of schools of geography at military establishments such as the US Military Academy at West Point in the early nineteenth century. These versions of military geography were not only instrumental (as one would expect) but also largely descriptive, and they emphasized the use of geographical knowledge, particularly location – via cartography and map reading – and physical terrain to facilitate military operations. Perhaps the closest connections between in-service military geography and the academic discipline came during the Second World War, when many professional geographers collaborated in the production of detailed regional geographies, for use in identifying targets and conducting offensive campaigns (Clout and Gosme, 2003; Barnes and Farish, 2006). Geographical knowledge remained crucial to the subsequent conduct of the Cold War, and its ‘hot’ campaigns in Indochina and elsewhere. Much of the traditional function of regional intelligence in the USA was contracted to programmes in area studies rather than geography, while the armed forces and intelligence agencies (on both sides) placed a premium on surveillance from air- and space-platforms, and new technologies of remote sensing, satellite photography and the like.

The repeated emphasis on regional knowledges and regional intelligence, even in more sophisticated, space-sensing technical forms, may seem to reduce military geography to what Woodward (2005) calls a ‘largely atheoretical, descriptive regional geography’, divorced from intellectual developments in the academic discipline at large. There are elements of truth in this, but two caveats are crucial. First, the technical elaborations of regional intelligence could be conceptual ones too; Barnes and Farish (2006) identify a series of vital connections between these seemingly commonplace activities and the conceptual ferment of spatial science and the quantitative revolution, and it is surely no accident that the Office of Naval Research in the USA took such a close (and often financial) interest in what might otherwise seem remarkably abstract spatial modelling and geographical research. Second, advanced militaries (and the paramilitaries that they now often find themselves fighting) have recognized the need to think of what the US Army now calls ‘battlespace’ as more than physical terrain. Wars have always depended on the visualization of space, but ‘battlespace’ not only has a much more complex geometry than conventional battle fields or theatres of war – it is no longer possible to make clear, linear separations between fronts (even during the First World War the front line decomposed into a bewildering maze of trenches and dugouts; contemporary conflicts transpose these geometries to the large scale) – but it is also increasingly understood as a human geography. The Pentagon has become increasingly preoccupied with urban warfare, which has required the construction of new, militarized models of cities and urbanization, particularly in the global south, a development that Graham (2009c; see also 2004a) calls ‘a new military urbanism’, while the experience of military occupation (see occupation, military) and the revival of counterinsurgency in the wake of the American-led invasions of Afghanistan and Iraq has prompted the US military to undertake a cultural turn of its own in order to map ‘the human terrain’ in ways that resonate, however awkwardly and imperfectly, with contemporary developments across the social sciences (Gregory, 2008b, 2009c).
MIMESIS

All of these issues can be studied critically, as most of the references above testify. But while Palka and Galgano (2000) suggest that writings such as these have cast ‘a persistent shadow on military geography as an academic discipline’, critical interventions in military geography, seeking to enlarge its compass beyond military circles, have only become a significant strand of work in HUMAN GEOGRAPHY in recent years: and over that same period many advanced militaries, particularly in Europe and North America, have redoubled and rethought their interventions in the production and appropriation of geographical knowledge. Significantly, these have involved far more than the direct application of geographical methodologies and knowledges to ‘kinetic’ (offensive) and now ‘non-kinetic’ operations: they have also involved a deepening engagement with the IDEOLOGY of MILITARISM.

mimesis Described in ancient aesthetics as the ‘imitation of nature’, mimesis is generally concerned with how REPRESENTATION in ART is related to truth, or how effectively a copy may mirror or make present an original scene or perception. Can the image reproduce an actual object as it is? Or does it merely reproduce the appearance of the object as it looks, as semblance? The question, famously allegorized in Pliny’s tale of a contest staged between two fifth-century painters, features centrally in Plato’s analysis of VISION and EPISODE. Plato’s answer is that representation is not only antipathetic to reality, but that the degree to which it aspires to lifelikeness is the degree to which it is adulterated, or distorted. While this remarkably ‘modern’ position prefigures present-day debates – from Marxian critiques of COMMODITY fetishism to the unmasking, within POST-STRUCTURALISM, of ‘given meaning’ – the mimetic tradition has been notably resilient. From the Italian humanists onwards (see HUMANISM), it has been thought of as the desire to bring nature towards its specular perfection. As an aesthetic formulation, mimesis also has applications within political PHILOSOPHY, especially within ENLIGHTENMENT struggles between custom and reason. Thus for Edmund Burke, as for David Hume, the perpetual forging of resemblances forms the condition for all human sociality: ‘It is by imitation, far more than precept, that we learn everything … It is one of the strongest links of society; it is a species of mutual compliance’ (Burke, 1906).

If mimesis in aesthetic theory refers us to the consensual and reproductive in social terms, it is no surprise that the concept has been variously modified and attacked in contemporary cultural and critical theory. Thus Adorno (1977), Lacoue-Labarthe (1989) and Derrida (1981) not only variously demonstrate how mimetic imitation subtends all of our institutions as well as our concepts of history and LANGUAGE. They also argue the ways in which a critique of mimesis requires us to rethink the relation between NATURE and technology, and to re-conceive the mediations between lived experience and aesthetic expression. From a different perspective, Homi Bhabha’s (1984) deconstructive appropriation of the mimetic principle has become a critical concept in post-colonial analysis, in which the colonized SUBJECT’s mimicry of colonial knowledge systems serves to estrange the basis of an authoritative discourse and so registers as a form of counter-domination (see POST-COLONIALISM).

minor theory A way of thinking that takes off from and builds upon Deleuze and Guattari’s (1986) notion of minor literature. It offers a means of working with material that self-consciously refuses ‘mastery’ in practices and claims, striving instead for a self-REFLEXIVE scholarship that subverts ‘major’ THEORY from within. Minor theory is a different way of ‘doing theory,’ a way of reading, writing, and talking that is insistently material – embodied, sensual, positioned – and refuses to ignore the different political-economic and social conditions in which knowledge is produced and shared. It recalls Adrienne Rich’s (1976) anguished call to ‘think through the BODY’ in the hopes of making a materialist knowledge streaked with the peculiar temporality and SPATIALITY of EVERYDAY LIFE (Katz, 1996). This SITUATED KNOWLEDGE is interstitial with and inseparable from ‘major’ productions of knowledge, and uses displacement to expose and chafe their limits so that they crack. In these cracks new knowledge and practice can emerge, but the process itself is transformative. In dynamic relation major theory, minor theory, and the relations that hold them in tension are reworked.

Deleuze and Guattari (1986) focus on the writings of Franz Kafka, a Czech Jew living in Prague, who wrote in German. They argue that Kafka was doubly displaced in this ‘major language’, which was neither his mother tongue nor the language of his community,
but that he pushed this displacement to its limits to create what they call ‘lines of escape’. Minor LITERATURE is about the conscious use of displacement to call into question and change dominant modes of writing and using language. By extension, minor theory is intent on making alternative SUBJECTIVITIES, SPATIALITIES and temporalities. It seeks to rework major theory from within, destabilizing received modes of knowing and the power/knowledge that produces and frames their objects. What is constituted as major or minor is historically and geographically specific. Deleuze and Guattari make clear that the major and minor are not different languages but, rather, different ways of working with the same language. This work – or play – can enliven and renovate language (and theory) so that it is made to express something new because the limits of its traditional forms are breached.

The idea of ‘becoming’ is crucial to Deleuze and Guattari’s notion of the minor. ‘Becoming’ suggests change and mutability, but also movement that ruptures, decomposes and recomposes. ‘Becoming’ invokes temporality, but its space is one of betweenness. Both work against the sort of dualism that would pit major against minor, or vice versa, but if the notion of becoming is to produce a critical politics, it must be understood as positioned somewhere (Braidotti, 1994; Katz, 1996). As a mode of thinking relationally, minor theory offers a means to reframe and move through theoretical impasses between, say, MARXISM and FEMINISM or local and global (cf. Massey, Allen and Sarre, 1999; Anderson 2000b). It can be a powerful strategy for recognizing and re-imagining DIFFERENCE; of thinking RACE through CLASS through GENDER, for instance, and through the iterative displacements such work calls forth, creating new spaces of and for political practice and engagement.

mobility There are two main uses of the term in HUMAN GEOGRAPHY: (1) the movement of people, ideas or goods across TERRITORY (physical mobility); and (2) change in social status (social mobility). Reflecting current interest, the journal Mobilities was instituted in 2006. Human mobility occurs over varying temporal and spatial scales, with MIGRATION referring to mobility that involves a change in residential location, whether within a city or across continents and daily mobility, including COMMUTING, referring to movements that do not entail a change of residence. Involving any one of a variety of means (e.g. feet, automobile, train, bicycle, airplane, wheelchair), mobility incurs costs in both time and money. As the costs of mobility have fallen (for example, the cost of sending a letter; the cost of travel between London and Mumbai), the separation between places has shrunk, a process known as TIME–SPACE CONVERGENCE, which has contributed greatly to GLOBALIZATION. In addition to incurring costs, mobility – the ability to move between and among places, whether on a daily basis or over the LIFE COURSE – also confers benefits; indeed, humans could not exist without some form of mobility, and at every geographical scale we have been consuming ever more of it. Because mobility is important for ACCESSIBILITY, it is often considered an important component of independence and quality of life (Hanson and Pratt, 1995), such that populations who lack the temporal or financial resources required for mobility (e.g. the elderly, CHILDREN or working parents with young children) become the focus of concern and mobility-enhancing programmes.

With the advent of telecommunications, physical mobility is no longer required for SPATIAL INTERACTION, and geographers have devoted considerable attention to understanding the complex relationship between physical mobility and virtual mobility (e.g. shopping for books on the INTERNET after browsing in a local bookstore). Whereas physical mobility does not require NETWORKS (one need not cross a meadow on a path), it is certainly enhanced by them, as movement is easier on a network than off of one. Virtual mobility does rely on network structures. For both physical and virtual mobility, networks are crucially important in channelling and shaping mobility patterns.

Social mobility, which refers to upward or downward changes in the socio-economic status of individuals or HOUSEHOLDS, has drawn considerable attention in URBAN and SOCIAL GEOGRAPHY. Of particular interest has been the relationship between social mobility and spatial mobility; in theories associated with the CHICAGO SCHOOL of urban sociology: for example, the upward social mobility that accompanied the assimilation of immigrants into American society took place via residential movement ever outwards from the urban core. Like other forms of mobility, social mobility also involves networks; the size, social composition and spatial location of a person’s network of social contacts can affect the probability of
upward or downward mobility (Granovetter, 1982; Hanson and Pratt, 1991).

**MODE OF PRODUCTION**

Karl Marx refined ‘mode of production’ to explain determinate ways of harnessing social labour to the transformation of NATURE. Nonetheless, Marx and Engels use the concept variously: sometimes as a unity in tension between ‘forces of production’ (technology, materials, human–environment relations) that fetter the transformation of ‘relations of production’ (PROPERTY, work, LAW, CLASS); while elsewhere, well-known passages from the Communist manifesto lend weight to an epochal, teleological interpretation of successive modes, including primitive communism, SLAVERY, FEUDALISM, CAPITALISM, SOCIALISM and, finally, COMMUNISM. Marx’s Capital systematically explores the dynamics of one mode of production, through COMMODITIES produced by ‘free labor’: dually freed from the means of production of necessities for survival, and free to sell all they have left, their capacity to labour, without obligations from workplace or employer. On this exploitation, Capital constructs ramifying, spiralling, anarchic forces of INNOVATION, class struggle, CRISIS, resolution and destruction – dynamics long debated as periodic or catastrophic (see DIALECTIC). Twentieth-century orthodox Marxists carried the burden that precise determination of the mode had vital political effects.

This orthodoxy was called into question, at least ‘West’ of the Iron Curtain, through the revisionist MARXISMS of the 1970s. The revival of ‘modes of production’ in the plural spoke to new exigencies: British Marxists broke with Stalinism and evolutionism, as social history reopened histories of transition to capitalism; scholars of DECOLONIZATION and DEVELOPMENT in AFRICA, LATIN AMERICA and ASIA questioned the politics and POLITICAL ECONOMY of peasantries (see PEASANT) in relation to capitalism and IMPERIALISM; and Marxist feminists questioned agrarian HOUSEHOLDS’ internal and external relations to MARKETS (see AGRARIAN QUESTION). A translation of Marx’s (1857) ‘Introduction’ to his *Grundrisse* exemplified a hinge between his early and late thought, calling into question an economicist, mature Marx. Passages from Marx’s corpus were re-read with an eye to ‘subsumption’ and persisting relations between modes of production. In debate with radical DEPENDENCY and WORLD-SYSTEMS theorists, French structuralists (see STRUCTURALISM) – in particular, the philosophers Louis Althusser and Etienne Balibar, economic anthropologists Claude Meillassoux and Maurice Godelier, and sociologist Nicos Poulantzas – conceived of internally systematic modes ‘structured in dominance’. Debates in Economy and Society, collected in Wolpe (1980) – including Wolpe’s own classic article on South Africa – questioned the historical and political articulation between the reproduction of capitalism and that of subordinate, pre-capitalist modes within the social formation.

Eric Wolf’s (1982) critique of Marxist structuralism appealed instead to consciousness and historical diversity, to show how ‘people without a history’ organized capitalist, tributary and kin-ordered modes of production in relation to a diffusing global capitalism. Talal Asad (1987) questions Wolf’s recourse to ‘permanent criteria’ in distinguishing modes rather than explaining complex histories of articulation to the unequally global history of capitalism. Instead, ‘articulation’ would have to contend with traditions, constructions, aspirations and conditions through which people could or could not participate in ‘making history’. Central to work in this vein since has been Stuart Hall’s (1980) reworking of ‘articulation’ as both ‘joining up’ and ‘giving expression to’: a Gramscian analytic that he uses to explain state-sanctioned RACISM as one form of cultural, material and political articulation of multiple modes.

**MODEL**

An idealized and structured representation of (part of) the world (cf. ABSTRACTION; IDEAL TYPE). Model-building has a long history in many sciences, but its formal and conscious incorporation into GEOGRAPHY is usually attributed to attempts to establish geography as a SPATIAL SCIENCE in the 1960s and 1970s. Scientificity was central to the benchmark collection of essays edited by R.J. Chorley and P. Haggett as Models in geography (1967). They treated models as ‘selective approximations which, by the elimination of incidental detail [or ‘noise’] allow some fundamental, relevant or interesting aspects of the real world to appear in some generalized form’. The accent on generalization was vital to their project, and this was achieved through visual-geometric representations of SPATIAL STRUCTURES and through mathematical-statistical generation of spatial patterns. The twentieth anniversary of the original Models was marked by an international conference attended by both revisionists who sought to rethink and revitalize the project and
dissidents who were sceptical of its ability to address what they regarded as more important questions. On one side, Harvey claimed that ‘those who have stuck with modelling since those heady days have largely been able to do so by restricting the nature of the questions they ask’. To Cosgrove, modelling was the quintessential expression of high MODERNISM, and the privilege it accorded to abstraction, functionality, generalization and simplicity was altogether incapable of responding to the challenge of DIFFERENCE in a late modern, even POSTMODERN, world. On the other side were a large number of unrepentant spatial scientists who had no time for such concerns, and who reaffirmed their faith in the central, INSTRUMENTAL importance of formal modelling. The publication of these exchanges two years later, as Remodelling geography (Macmillan, 1989) coincided with a radically different collection edited by R. Peet and N. Thrift entitled New models in geography (1989). Their subtitle indicated a tectonic shift in the foundations of model-building: ‘the political-economy perspective’ signalled a range of different approaches that had a common grounding in various forms of POLITICAL ECONOMY, CRITICAL SOCIAL THEORY and HISTORICAL MATERIALISM. Partly as a consequence, the original claim for analytical model-building as the central object of geographical enquiry: ‘That there is more order in the world than appears at first sight,’ Haggett and Chorley reminded their readers, ‘is not discovered till the order is looked for.’ Since then, many human geographers have been drawn to forms of cultural and social theory that insist on the radical non-innocence of just ‘looking’, and NON-REPRESENTATIONAL THEORY, POST-STRUCTURALISM and SCIENCE STUDIES (among others) have directed attention towards the ways in which ideas and images enter directly into the very constitution – the ‘ordering’ – of the world.

**modernism** Strategies of REPRESENTATION closely identified with late-nineteenth- and twentieth-century movements in the arts that challenged the conventions of romanticism and REALISM. There are many modernisms, but Lunn (1985) identified four common preoccupations:

1. **Aesthetic self-consciousness.** ‘Modern artists, writers and composers often draw attention to the media or materials with which they are working’ and in doing so emphasize that their work is a fabrication in the literal sense of ‘something made’; they thus seek to escape from the idea of art as a direct reflection of the world (cf. MIMESIS).

2. **Simultaneity and juxtaposition.** Modernism often disrupts, weakens or dissolves temporal structure in favour of simultaneity: different perspectives are often juxtaposed within the same frame or narrative.

3. **Paradox, ambiguity and uncertainty.** Modernism often explores ‘the paradoxical many-sidedness of the world’: instead of an omniscient narrator, for example, modernist writers may use multiple points of view.

4. **The demise of the centred subject.** Modernism often exposes and disrupts the fiction of the sovereign individual or the ‘integrated subject’.

Modernism did not emerge in a vacuum: it was a critical response to a series of crises within capitalist MODERNITY. Its coordinates included: the explosive growth of modern cities and the radical transformation of their built forms, economies and cultures; the restructuring of European CAPITALISM, especially through the Agricultural Depression at the end of the nineteenth century and the intensified technical changes brought about by a new round of INDUSTRIALIZATION; the aggressive advance of European COLONIALISM and IMPERIALISM; and the turbulence of the First World War and the Russian Revolution. This mapping has three implications of direct relevance to HUMAN GEOGRAPHY:
MODERNISM

(1) These episodes involved significant changes in conceptions of time and space in the west (Kern, 1983) which also had dramatic repercussions far beyond the shores of Europe and North America. Huyssem (2007) insists that modernism 'cut across' imperial and post-imperial cultures – it included Baudelaire's Paris and Joyce's Dublin, but also Borges' Buenos Aires and Kahlo's Mexico City – so that 'metropolitan culture was translated, appropriated and creatively mimicked in colonized and post-colonial countries in Asia, Africa and Latin America'.

(2) The ways in which these changes were registered in the arts, literature and elsewhere were profoundly gendered and sexualized. 'The territory of modernism,' Pollock (1988, p. 54) argues, 'so often is a way of dealing with masculine sexuality and its sign, the bodies of women'. Representations of modern spaces were made to revolve around masculine subject-positions – like the mobile figure of the flaneur – and to privilege encounters 'between men who have the freedom to take their pleasures in many urban spaces and women from a class subject to them who have to work in those spaces often selling their bodies to clients or to artists'. Indeed, Lefebvre's account of the production of space, which was partly inspired by his encounters with surrealism and the Situationists, repeatedly draws attention to the significance of modernism for the triumph of a 'visual-phallic-geometric space'.

(3) Modernism was connected not only to experimentation in the arts, but also to new styles of philosophical reflection and to the formation of the social sciences (including critical theory and Western Marxism, Lunn's primary concern). But most of these intellectual projects retained the social markings, marginalizations and exclusions written into metropolitan modernism.

Lunn's characterizations work best when applied to modern art and literature and probably have less purchase on modern architecture, which has its own chronologies (Frampton, 1992). These architectural motifs assumed a wider significance in the 1950s and 1960s, when a high modernism emerged as a dominant cultural thematic, distinguished by what Bürger (1992) described as a 'pathos of purity'. 'In the same way as architecture divested itself of ornamental elements,' he argued, so 'painting freed itself from the privy of the representational, and the nouveau roman liberated itself from the categories of traditional fiction (plot and character).’ In much the same way, too, spatial science divested human geography of an interest in the particularities of areal differentiation, which became so much 'surface noise', in order to reveal the purity of geometric form and spatial structure (often, like architecture, cast in terms of functionalism). It would not be difficult to present other high modernist movements in social thought in much the same way, notably structuralism.

From such a perspective, postmodernism becomes a critique of high modernism rather than of modernism tout court. It contains important echoes of the early-twentieth-century avant-garde, and a number of writers have urged the reclamation of that earlier modernism as an indispensable moment in the formulation of critical social theory. In fact, Berardi (1983) suggests that it had its roots even earlier, in the nineteenth-century writings of Baudelaire and Marx, both of whom (in different ways) sought to come to terms with a world in which 'all that is solid melts into air'. Those human geographers most invested in these reclamation projects have paid close attention to the historical–geographical coordinates of modernism (above). Thus Harvey (1989b) sought to expose some of the connections between the cultural formations of modernism, the experience of time–space compression and the changing political economy of capitalism, which in turn provoked a critique of the ways in which his own representations erased the characteristic gendering and sexualization of their maps of modernity (Deutsche, 1996c). There have also been specific studies: Harvey's (2003a) excavation of modernism and its material foundations in nineteenth-century Paris, and Pinder's (2005c) exploration of forms of utopian modernism in the twentieth century (see situationism).

But the most deliberately modernist contributions to contemporary human geography are to be found in the work of Gunnar Olsson and Allan Pred. Pred's experimental studies of European modernities (1995) and his extraordinary re-creation of a 'heart of darkness' at the very centre of 'Swedish modern' (2004) were freely informed by the example of Walter Benjamin; they beautifully exemplify all four of Lunn's diagnostics (above) and the radical, critical impulse of early modernism that
Berman so admires. In a transposed key, Olsson’s (2007) critique of CARTOGRAPHIC REASON recalls those earlier modernisms too, and stages crucial encounters with the art of Duchamp, Malevich and Rothko; but its careful minimalism also reinscribes the pathos of high modernism in a newly critical register. Taken together, these thought-works show that modernism still has much to contribute to the jaded critical cultures of human geography (and much more besides).

**modernity** A notoriously ambivalent and highly contested concept, the notion of ‘modernity’ has nonetheless acquired wide currency within HUMAN GEOGRAPHY, not the least prompted by the proliferation of ideas drawn from POSTMODERNISM in the 1980s and 1990s. Broadly speaking, the term has been used to designate a number of discrete, yet interrelated, phenomena that, in most cases until recently, place EUROPE at the centre of the world stage (see EUROCENTRISM):

1. First and foremost, modernity is used as a means to periodize European (and, by implication, ‘world’) history by designating a distinct epoch. The boundaries surrounding this ‘modern’ epoch are unclear, starting as early as the dawn of the Italian Renaissance (fourteenth century), through the invention of the printing press (fifteenth century) to the INDUSTRIAL REVOLUTION (eighteenth and nineteenth centuries). As Bauman (1993, p. 3) put it: ‘How old is modernity?’ is a contentious question … There is no agreement on dating. There is no consensus on what is to be dated.’ Common to all epochal definitions, however, is the idea of a break with the past: with established modes of REPRESENTATION, for example, with economic practices and regimes, with technologies, or with cultural and social relations.

2. Modernity is also used to designate a particular mental attitude that seeks rationally to understand the world we live in by finding order within and achieving domination over NATURE (cf. Withers, 1996). Here, ‘modernity’ becomes synonymous with the notion of progress and gradually affects most areas of life, from the medicalization of bodies and environments to the rationalization of urban life through the discourse of PLANNING (see also BIOPOWER). SCIENCE and the pursuit of knowledge in the wake of the European ENLIGHTENMENT was central to this evidence-based spirit of modernity, which finds its perfect geographical expression in the notion of Cartesian, isotropic SPACE. Aspirationally, it is perhaps best captured by Kant’s famous 1784 maxim, sapere aude, or ‘dare to know’.

3. A third dimension employs ‘modernity’ to designate a thoroughly secular project of liberation and emancipation that arguably culminated in the related American and French Revolutions of the late eighteenth century, and which led to the emancipation of slaves and the establishment of HUMAN RIGHTS across a range of differences. This ‘political’ modernity heralds a set of historical tasks that seeks the implementation of novel forms of political representation, of legal and social rights of individuals, and of justice in a host of different contexts (cf. Schama, 1989; Howell, 1993; Delaney, 2001: see also LIBERALISM).

4. A final sense in which the concept of ‘modernity’ is used specifies a particular process of global incorporation that leads directly from the Age of Exploration to the European COLONIALISMS of the nineteenth and twentieth centuries. In this context, 1492 marks the dawn of a new era: the beginning of GLOBALIZATION within and through a set of clearly structured, if historically developing, CORE–PERIPHERY relationships (Taylor, 1999) and motivated, perhaps, by what Max Weber famously described as a ‘protestant work ethic’. The most basic element to this notion of modernity is the NATION-STATE and its territorially expanding capacity to organize and make social processes anonymous (see also Harris, 1991).

Thus, it would seem best initially to conceptualise ‘modernity’ as a broad semantic field marked by tensions, contradictions and possible DIALECTICAL energies, rather than streamlining them into an organic totality. The concept is thus implicitly linked to other concepts such as CAPITALISM, ‘nation-state,’ MOBILITY, literacy, DEMOCRACY and URBANIZATION, to name but the most prominent. Any one of these, individually or in combination, are customarily invoked when attempting to define ‘modernity,’ so much so that often the
link is established by rendering modernity as an implicit adjectival, and thus clarifying, part of any of the nouns just listed. In other words, while ‘ways of thinking’, ‘economic practices’ or ‘modes of transportation’ become paradigmatically different by being prefaced and hence associated with ‘modern’, ‘democracy’ and other key concepts appear semantically to embody ‘the modern’ as such. Furthermore, throughout its history (however conceptualized), ‘modernity’ has been contested (e.g. the Counter-Reformation in the seventeenth century, the Romantic Movement in the late eighteenth century, the back-to-nature movements of the late nineteenth century, the student and worker uprisings associated with May 1968, or the current religious revival, especially in the USA).

What perhaps unites most definitions of ‘modernity’ is an emphasis on the notion of the ‘new’. Modernity is synonymous with change and thus becomes a declared enemy of traditions. This is the root of many subsequent binary distinctions that characterize modernity: the ‘new’ is explicitly set apart from the ‘old’ – and it is the distance between the two that acquires explanatory power. The importance of this threshold is encapsulated in the different figures employed to characterize modernity: Georg Simmel’s ‘stranger’, Max Weber’s ‘adventurer’, or the ‘FLÂNEUR’ and the ‘gambler’ invoked by Walter Benjamin all emphasize a border, be it between inside and outside, old and new, presence and absence or PRIVATE AND PUBLIC (Shields, 1992; Strohmayer, 1997). It is in the nature of such borderlines to invoke an ‘uncanny’ sense of existence where the ‘new’ constantly has the power to threaten or disrupt, as exemplified in Fritz Lang’s 1931 film *M*.

The notion of the ‘new’ (and the close, intertwined relationship between modernity, and filmic and urban space: see FILM) also points us towards another geographical context surrounding modernity: its thoroughly urban, or better yet metropolitan character (Ogborn, 1998; Frisby, 2001; Pile, 2005). It is in urban settings that the ‘new’ materializes an exuberant side of modernity, where the ‘new’ is not synonymous with order but paradoxically becomes associated with a set of practices subverting traditions (Berman 1983). The undermining of sexual mores, diversification of CONSUMPTION practices, the rise in artistic freedoms and forms of expression culminating in the notion of an avant-garde, the growth in new and decidedly urbane forms of ‘destructive’ capital assem-

bled in the hands of the bourgeoisie so effectively analysed by Marx, or simply the development of different lifestyles all encompass ‘experiences of modernity’ (Frisby, 2001, p. 2; see also Glennie and Thrift, 1992) that are not so easily, if at all, attained in non-urban spaces. Small wonder, then, that it takes another quintessentially modern and urban figure, the detective (as exemplified by virtually any film noir), to reorder a world threatening to become unreadable. The urban has become synonymous with the ‘modern’ in another sense as well: novelty principally also attaches to architecture, where ‘order’ translates into a functional approach to questions of housing and urban design (Dennis, 1994; Heynen, 1999). L.H. Sullivan’s phrase that ‘form (ever) follows function’ (1896) and A. Loos’ insistence that ‘ornament is crime’ (1908) together capture the architects’ aspirations materialised in modern buildings. Rather crucial for any understanding of modernity is the tension emerging at the heart of this and related ‘ordering’ impulses: the tension between any order given or imparted upon architecture or urban design and the restless, destructive tendencies embodied by the ever-changing nature of ‘the new’ (Donald, 1999: see MODERNISM). As postmodernists would later lament (and remaining within Loos’ dictum), ‘order’ thus becomes its own ornament.

A solution to this impasse is offered by a further element common to many definitions of modernity: the projection of ‘progress’ on to constantly developing technologies. Effectively reconciling the notion of ‘the new’ with the desire (or necessity) to impart order, the very idea of ‘progress’ imparts a sense of direction to ‘modernity’ and thus renders it potentially legible. Trusted or not, technological developments ranging from seafaring innovations, the invention of paper moneys, the steam engine, entertainment technologies such as panoramas or the cinema to the INTERNET of our present age all impacted upon everyday life in a way that has lent credence to the idea of an ephemeral and constantly changing; that is, a modern world that is defined by its technologically progressing nature (Asendorf, 1993). As this listing implies, these technologies have threaded different places into new conjunctions, and the intensification of multiple processes of TIME–SPACE COMPRESSION under contemporary modes of GLOBALIZATION has reworked both senses of PLACE and structures of SPACE (Entrikin, 1991; Hetherington, 1997b; Oakes, 1997).
Modernity does not, of course, merely denote a set of particular constellations characteristic of the material world. In addition to such historically contingent interpretations of modernity (or interpretations of the world through the lenses crafted by ‘modernity’), a number of critiques of modernity have been formulated within PHILOSOPHY and the social sciences, themselves a direct product of modernizing tendencies within society at large. Perhaps chief amongst these is the recognition that the quest for order inherent in many modern tendencies embodies an element of systemic control that has been used historically to suppress progressive movements. Examples include the rationalization of urban space in Haussmann’s Paris, seen by contemporaries as the very ‘capital of modernity’ (Harvey, 2003b), the BIOPOLITICS and the central function of MARKETS under NEO-LIBERALISM. Returning to the four main definitions of modernity presented above, we may thus infer a formative tension, not to say contradiction, between modernity as scientific progress and modernity as an emancipatory project. Even so, to state matters in this way may well imply an all too overt reliance on modern ways of seeing. As Bruno Latour has insisted, most attempts to infuse a clear sense of ‘order’ have always been implicated in non-ordered, HYBRID and networked social practices (cf. Swyngedouw, 1999).

Another critique that has gained wide currency in the geographical literature is that modernity is inherently REDUCTIONIST in its insistence on the primacy of the ‘eye’ over other sensual modes of connecting to the world (see also VISION and VISUALITY). Chiefly building on the work of Walter Benjamin and the writings of Guy Debord and the SITUATIONISTS, this strand of critique centres on the importance of optical METAPHORS and instruments in modern environments (Crary, 1990a). From René Descartes’ early-seventeenth-century insistence on the importance of evidential modes of reasoning to telescopes, microscopes and cameras, through the optically structured spaces of modernity such as the arcades, boulevards and parks (Ogborn, 1998; Strohmayer, 2006), to ‘ocular’ writing in general with its focus on LANDSCAPES and the mappable nature of events (Guarassi, 2001; Dubbini, 2002: see also CARTOGRAPHIC REASON), modernity is characterized as a mode of engaging with the world that favours visual relations over and against other modes of connecting with and being in the world. As before, this critique has a double edge: it attaches to a ‘modern’ world that has become increasingly reliant on visual modes of communication, while also being critical of modes of understanding the modern world that in turn rely on visual technologies, rhetoric and categories. The ensuing dual practice of deploying the visual both as a structuring principle informing modern spaces and as a mode of understanding such spaces has perhaps best been characterized in the notion of the SPECTACLE, as critically developed by Debord (1994).

Central to this critique is the reliance common among critical social scientist and geographers alike on that which arguably requires critique itself: visual modes of existence. We ‘shed light’, we ‘illuminate’, we ‘enlighten’ – all the while the world we live in has become saturated with visual forms of commerce, information and entertainment. In other words: the critique of modernity all too often relies on modern modes of communication and exchange, rendering it vulnerable to the charge of being but another mode of consumption and distraction. Theodor Adorno and Max Horkheimer’s earlier disenchantment with an Enlightenment, and their claims that modernity had surrendered its better impulses to an ‘entertainment industry’ are akin to this critique.

In all of this it is important to remember that such dis-enchantment, especially in the context of the twentieth century, was often brought about by real and often life-threatening CRISIS experiences. Nazism in particular and its thoroughly rational implementation of the HOLOCAUST, but also the Stalinist experiments, Hiroshima and the constant development of UNDERDEVELOPMENT structurally endemic to modern capitalism have all contributed (see also WAR). So too have those politico-legal responses to modern crises that have worked to produce an ‘outside’ to the modern, a heterogeneous and dispersed space of EXCEPTION where particular groups of people are expelled from the privileges and protections of the modern even as they are made subject to its disciplines and punishments (Minca, 2007a).

For some commentators, this disenchantment inspired the development of the concept of ‘POSTMODERNITY’. Others have seen fit to speak of a second modernity (e.g. Beck, 1992) or of hypermodernity (e.g. Pred and Watts, 1992). More interesting still, given the complexities surrounding the term and its thoroughly EUROCENTRIC origins, are recent developments that attempt to broaden the linguistic field surrounding ‘modernity’ (Gilroy, 1993; Appadurai, 1996; Gaonkar, 2001; Venn and Featherstone, 2006: see also Martins and Abreu, 1996;
Power and Sidaway, 2005; Walton-Roberts and Pratt, 2005). The resulting post-colonial notion of ‘modernity’ aims to reconcile the often devastating impact that modernity has on non-Western cultures and societies with the progressive, emancipatory impulse also associated with modernity (see POST-COLONIALISM). Acknowledging that modernity has impacted unevenly across space, the focus of these often surprisingly modern investigations is chiefly on the concrete negotiations that contextualize adaptive or rejective practices locally in a global setting. Gilroy’s (1993) studies of the complex formation of a ‘Black Atlantic’ exemplify this strand of scholarship. The main innovation of such work resides in its willingness to break with a notion of linearity that has characterized notions of modernity from Descartes to Hegel (see Duncan, 2002). At the same time, and in close analogy to other attempts to broaden analytical concepts, any gains achieved need to be measured against losses in clarity, argumentative bite and explanatory power: ‘broadening’ often also entails elements of diluting argumentative claims. In the case of ‘modernity’, with (as we have seen) its already wide semantic field, the abandonment of linearity carries the risk of no longer being able critically to differentiate if, or to what extent, societies (or elements thereof) can meaningfully be compared through the use of the conceptual apparatus developed in conjunction with the term ‘modernity’. In the absence of such comparative yardsticks, how can scholars translate findings from one geographical locale to another?

In fact, ‘translation’ may well be an apt term to use within modern DISCOURSES. Translations have always posed quite fundamental problems in that acts of translation tend to reduce a semantic multitude to more circumspect and singular set of equivalences. Attributing modernity to this process at least has the practical virtue of ensuring compatibility at a relatively accessible point in an argument. Traditional notions of modernity would, for instance, have firmly placed practices associated with or emanating from ‘witchcraft’ as being either pre-modern or outside the realm of the modern by presupposing incompatibility between the two terms. The very thought of ‘alternative modernities’ (Gaonkar, 2001) undermines this robust principle. By ensuring that translation between different practices can always involve or lead to a broadening of categories or non-linear historical trajectories, the notion of ‘the modern’ risks the loss of normative aspects associated with modernity as an emancipatory and, in the words of Jürgen Habermas, an ‘unfinished’ project (see CRITICAL THEORY).

Arguably, many debates currently taking place in the first decade of the new millennium labour with precisely this point: the possibility of the universality of modern dreams, aspirations and normatively inspired practices. Can we think of ‘modernity’ in the absence of pre-formulated yardsticks, or clearly associated practices? Whether we invoke the notion of a ‘clash of cultures’, a re-investigation of notions of ‘tolerance’ or insist on established, modern norms (especially in the legal context) in the face of challenges, we are talking about modernity and its survival into an increasingly less certain future. Modernity may yet prove its most enduring qualities by remembering its own inherent insistence on the importance of the ‘new’. In geographical terms, this ‘new’ translates into an insistence on the importance not of preserving a status quo but of constant experimentation and improvement (Toulmin, 1990). In other words, it involves a resolve to preserve and produce alternative spaces of modernity, rather than spaces of alternative modernities.

Suggested reading

modernization Often conflated with DEVELOPMENT in general and Westernization in particular, modernization describes processes unleashed by the transformation of traditional societies into capitalist ones or by their incorporation through adaptation into an increasingly globally operating form of CAPITALISM. If the former process is traditionally held to characterize the transformative processes attaching to Western societies in the context of the nineteenth century, it is the latter, non-indigenous form of modernization that has come to dominate the world since the end of the Second World War. As such, notions of modernization partake in discourses of the evolutionary transformation of societies and are often deeply implicated in notions of progress, growth, liberalization and the DIFFUSION of particular values. Up until fairly recently, such processes of modernization were thought to entail a clearly legible and often TELEOLOGICAL register of changes in the economic, cultural, social and political sphere of societies undergoing transformation. Not so any more. Initially criticized for being too narrowly focused on economic forms of modernization and for disregarding the many different direct
and indirect costs linked with modernization processes, attention has also moved to forms of contestation and resistance that accompany and often undermine modernization processes (Scott, 1985; Nabudere, 1997).

More recently still, the term has been recast as reflexive modernization in the work of Ulrich Beck and others (cf. reflexivity). Rather than following a preset and, indeed, general path (see modernity), modernization is now thought to entail the ability constantly to adapt and thus to create a 'second modernity'. Where older modernization discourses argued with reference to timeless and abstract principles, a newer and reflexive practice seeks constantly to review its goals and practices in dialogue with incoming information. Key in this attempt is the geographical term 'boundary', which is seen less as a fixed entity than a conscious practice (Shields, 2006): just as boundaries emerge from processes of negotiation and remain open to future negotiations, reflexive modernization both relies on the boundedness of its practices while acknowledging their potential for change. Structurally similar to recent attempts to broaden the notion of 'modernity' by incorporating non-Western practices, reflexive modernization thus constitutes a discursive process, rather than marking the outcome of discursive practices, as older notions of modernization had attempted to do (see discourse). It is hence no surprise to see the term 'reflexive modernization' often being conflated with the notions of 'third way' or 'third (or 'new') modernity'. Likewise, the realization that modernity may well have become a problem in its own right shares the key assumption of a required discursive openness with reflexive notions of modernization. Principally, such problematization takes place through the recognition that unintended consequences within industrial societies, which proliferate as risks beyond the accepted certainties, are created within modernity. In this form, 'reflexive modernization' has been heralded by many as an agency-orientated alternative to postmodern discourses and attitudes (Beck, Bonss and Lau, 2003) and is related to structuration theory (Beck, Giddens and Lash, 1994). US

modifiable areal unit problem (maup) A particular form of ecological fallacy associated with the analysis of spatial data sets, in particular those in which data on individual observation units (such as households) are aggregated into areal units (such as census tracts and counties) for analysis.

Robinson (1950) provided the classic exposé of the maup for social scientists (see also Gehlke and Biehl, 1934), in which he showed that a high correlation between two variables (the percentage of the population who were African-American and the percentage who were illiterate) at the state scale within the USA was not replicated at the individual level; in other words, whereas the aggregate data analysis showed that states with more African-Americans also had more illiterates, leading to the ecological inference that African-Americans were more likely than non-African-Americans to be illiterate, this strong claim could not be substantiated by analyses of individual level data. (The correlation coefficient for the state-level analysis was 0.946, but for the individual level it was much smaller, at 0.203.)

The maup was introduced to the geographical literature by Openshaw (1977; see also Openshaw and Taylor, 1979), whose empirical studies corroborated and extended Robinson's. With one data set, for example, they showed that different aggregations (or regionalizations, since most geographical examples involve aggregations into territorial blocks) could generate correlation coefficients covering almost the entire potential range from −1.0 to +1.0 (in one example, the range found was −0.73 to +0.98), although most distributions were leptokurtic, with the majority of observed coefficients close to the median value. They showed that the problem is made up of two components. With the scale effect, there is a tendency for larger correlations to be associated with larger (and thus almost invariably a smaller number of) spatial units. The aggregation effect refers to the large number of different ways in which individual units can be combined into a set of areal units – usually with constraints such as size and contiguity (Openshaw, 1982).

The maup is important in many areas of spatial science using quantitative methods, because it indicates the need for caution in inferring a relationship between two variables based on a single aggregation at a particular scale: a result identified from one such analysis may not be replicated exactly in another. Openshaw and Taylor (1981) identified three possible responses to the maup:

- it is an insoluble problem, and so can only be ignored;
MONEY AND FINANCE

- it is a problem that can be assumed away, with the results obtained from the particular available data set being accepted as 'the real ones'; or
- it is a very powerful analytical device for exploring various aspects of geography and spatial variations, since alternative regionalizations can be produced – this allows the creation of both frequency distributions with which one regionalization can be compared and, in some cases, optimal regionalizations for particular purposes (see CLASSIFICATION AND REGIONALIZATION).

Although the existence of the maup is widely recognized as posing a problem for much SPATIAL ANALYSIS, in very many cases researchers have had to adopt either the first or the second of these positions because they are constrained by available data sources (especially those provided by CENSUSES). Attempts have been made to develop methodologies that can take the maup into account and produce unbiased ecological estimates (as in the work of Holt, Steel, Tranmer and Wrigley, 1996, and King’s, 1997, classic volume on solving the ecological inference problem; see also a recent overview in Swift, Liu and Uber, 2008), but few analysts have adopted the third of Openshaw and Taylor’s suggested responses, preferring to accept the outcome of one aggregation as providing a reliable estimate of the ‘real’ relationship.

The maup is not only an issue in spatial analysis: it is also relevant to a range of practical issues – notably REDISTRICTING. Many electoral systems use territorially defined constituencies, which comprise aggregations of smaller territorial units; UK Parliamentary constituencies, for example, are aggregations of contiguous local government electoral wards with a size constraint. Johnston and Rossiter (1982; see also Cirincione, Darling and O’Rourke, 2000) have shown that there is a large number of possible solutions to the constituency-building problem in every area, which can produce different election results, so that the selection of a particular aggregation can not only lead to a particular outcome in one constituency (hence the widespread practice of gerrymandering in some countries), but can also contribute to considerable bias in election results, whereby not only is the percentage of seats won by a party disproportionate to its share of the votes cast, but other parties with the same share of the votes might win very different shares of the seats (Johnston, Pattie, Dorling and Rossiter, 2001: see ELECTORAL GEOGRAPHY).

money and finance HUMAN GEOGRAPHY was late in recognizing the geographical significance of money and finance, with few attempts to write geographies of money and finance much before the 1980s (for exceptions, see Conzen, 1975, 1977). However, since then a new sub-field of geographical research has emerged (Corbridge, Thrift and Martin, 1994; Leyshon and Thrift, 1997; Martin, 1999; Clark, 2005a). As this work has evolved, it has followed a similar trajectory to the wider discipline, with earlier work being influenced by more abstract economic and SOCIAL THEORY, while more recent work has tended towards substantive, cultural accounts of the geographical consequences of money and finance.

The first systematic engagement with the geography of money and finance emerged from MARXIST analyses of the broader dynamics of CAPITALISM, best exemplified by the work of David Harvey (1989b, 1999 [1982]). Marx drew attention to the role that money and finance played in the financial system within capitalism, which revolves around money and the social power that its possession delivers in a MARKET economy. Drawing on this insight, Harvey developed the concept of TIME-SPACE COMPRESSION, which provided a propulsive element to earlier theories of a shrinking world, such as TIME-SPACE CONVERGENCE and TIME-SPACE DISTANCINATION. The social power of money increases the pace of life over time as part of a generalized process to reduce the turnover time of capital, and the faster realization of profits and incomes. This encourages the introduction of new space-shrinking technologies, bringing in their wake the progressive dislocation of economic and political systems. Money has become ever more mobile and fungible, and is now the most heavily traded COMMODITY in the global ECONOMY. The sheer weight of money in circulation within and between financial markets has made governments more sensitive to their operation, and economic development has been destabilized by a series of serious financial CRISES in various parts of the world, including LATIN AMERICA and Sub-Saharan AFRICA in the 1980s (Corbridge, 1993a), and South East Asia and Latin America (again) in the 1990s (Beaverstock and Doel, 2001;
Webber, 2001; Rock, 2002). These crises have often been caused by the movement of hot money, which moves in but, significantly, also out of economies at short notice in search of investment opportunities. Growing attention is being paid to such investors, such as hedge funds and pension funds, which control large volumes of capital in circulation within the global economy. For example, Clark (1999a) has argued that the current era is characterized by ‘pension fund capitalism’. The rise of these institutions has coincided with the retreat of the state, particularly within Anglo-American economies. As voters have demonstrated their unwillingness to pay the taxes that would fund social welfare programmes and public infrastructure development, so large institutional investors have moved in to fill the gap, footing the bill, but for private gain. This has implications not only for what kind of infrastructure is built, but also for how it is run. Similar arguments about the growing power and influence of the financial system have been made in a body of work that emerged in the early twenty-first century, which has a focus on the process of financialization, which has focused on the ways in which money and finance has been colonizing economic life, both in the boardroom (Froud, Sukhdev, Leaver and Williams, 2006) and in the household (Langley, 2004, 2006).

A second area of research has focused on the regional effects of money and finance, mainly through the impacts of the reorganization of the financial services industry. Since the 1970s, and working in parallel to, and combination with, the process of financialization, there has been a process of neo-liberalization that has brought about a wave of financial re-regulation to economies in North America, Europe and South East Asia (Moran, 1991, 2003; Dymski, 1999). These developments have brought about an increase in retail financial services employment, and economic geographers have documented and explained these uneven geographies of growth (Leyshon, Thrift and Toomey, 1989; Richardson, Belt and Marshall, 2000) (see neo-liberalism).

A third area of work has focused on the urban dynamics of money. One strand of research has sought to explain the persistence of financial centres in an era of time-space compression. Geographers have sought to explain why financial centres such as the City of London and New York continue to control the majority of the world’s financial activity (Thrift, 1994a; Agnes, 2000; Clark and Wojcik, 2001). The answer is to be found in the ways financial centres facilitate close interpersonal contact through episodes of co-presence. This facilitates the rapid generation, capture, interpretation and representation of business information (Boden and Molotch, 1995; Boden, 2000). The financial centre may therefore be seen as a collective way of coping with the vast amount of monetary information that circulates within the global economy. It is a centre of financial expertise founded in a complex division of labour embodied in the skills of the workforce, technology, and textual material (Thrift, 1994a), and which collectively generates and disseminates financial information as well as interpretations and narratives about what this information actually means. This is the reason why it is unlikely that financial centres ‘will simply melt away into a generalized “space of flows”’ … leaving money obligations to speed their way along the cables and through the aether [sic], to and from many different terminals located in places’ across the global economy (Thrift, 1994a, p. 327). A second strand of research focuses on the urban dynamics of money upon spaces of financial exclusion, the process by which people of poor and moderate incomes are directly and indirectly excluded from the formal financial system and denied access to mainstream retail financial services (Leyshon, Burton, Knights, Alferoff and Signoretta 2004a; Dymski, 2005).

A fourth area of research has focused on geographies of money as they are played out through institutions and individual actors. A particular focus of this work has been on the bodies that perform tasks in the service of the financial system. This work has focused in the main on the changing ‘gender cultures’ of financial institutions (Jones, 1998), such as the transformation of cultures of paternalistic masculinity within British retail banking (Halford and Savage, 1995), and analyses of labour market segregation within the City of London, and the ways in which highly paid jobs in corporate finance and trading are implicitly and explicitly coded as masculine.

A fifth and final area of research has been that which has focused on local currency systems, such as Local Exchange and Trading Systems (Lee, 1996; Lee, Leyshon, Aldridge, Tooke, Williams and Thrift, 2004). This work, influenced by debates on diverse or alternative economies, has sought to explore the moral geographies of money and exchange, and the possibilities of local communities of creating their own systems of exchange based more on the pursuit of social
and welfare gains, rather than narrow financial advantage (Williams, 1996; Williams, Aldridge, Lee, Leyshon, Thrift and Tooke, 2001; Maurer, 2003).

monuments Built icons of identity usually in the form of public statues or symbolic buildings that are designed and executed to evoke a sense of national and regional identity, and to induce in the collective imagination remembrance of specific events or people. Although the study of monuments has increased in human geography over the past 20 years, a result of a heightened interest in the symbolic, ritualistic and performative dimensions of identity formation, historians were the first to explore the relationships between public monuments and nationalism. Mosse’s (1975) study of the role of the public statue in the development of German nationalism is still an exemplary analysis, while Schorske’s (1979) discussion of the redevelopment of Vienna’s Ringstrasse in the nineteenth century provides a brilliant interpretation of the role of Austria’s rising middle class in impressing their political vision on the architecture of the city.

There are several reasons for studying the links between monuments and political-cultural identities. First, the erection of public monuments in public space has proliferated since the nineteenth century, and this expansion of public statuary corresponds with the heyday of nation-building projects. Second, unlike other arts such as painting or literature, monument-making is usually a collective process ‘more democratic than painting because it is simpler and more solemn, more appropriate to the public square, to huge dimensions, and to emblematic figures that are both a product of, and stimulus to the imagination’ (Agulhon, 1981, p. 4). Third, the rituals surrounding the unveiling of monuments and the dynamics of their reception and consumption help us to identify their role in the public consciousness. Icons in bronze or stone are made meaningful by the ways in which they visually and verbally invoke particular versions of identity. Finally, the spatiality of public statuary is important in the constitution of meaning and it is here that geography has a particular contribution to make (see also memory).

A seminal geographical study of a monument is Harvey’s (1979) analysis of the Basilica de Sacré Coeur in Paris and its role in the development of class politics in the capital. Subsequent studies have pursued several different themes. Studies of the role of war monuments in articulating national and sectional commemoration range from extensive surveys of memorials to the two world wars (Heffernan, 1995; Johnson, 2003b) to in-depth studies of individual statues (Till, 1999). These analyses pay close attention to the iconographic debates surrounding the use of particular motifs (see Iconography) and to the conflicts over identity engendered by them. The spatiality of commemorative sites has been another focus: Leib’s (2002) analysis of the Arthur Ashe statue in Richmond, Virginia, for example, highlights the role of place and race in the public discussion of the location of the monument, while Benton-Short (2006) recovers the politics of location that animated recent discussions of monuments and memorials on the Mall in Washington, DC. All of these studies focus on the visual and verbal languages surrounding public monuments, but more recently human geographers have started to address the performative dimension by examining the textual and non-textual, bodily and non-bodily practices involved in the making of public icons (e.g. Howe, 2008).

moral geographies The study of the inter-relationship of moral and geographical arguments. Work has considered the way in which assumptions about the relationship between people and their environments may reflect and produce moral judgements, and how the conduct of particular groups or individuals in particular spaces may be judged appropriate or inappropriate. D.M. Smith (1998a) sees moral geographies as one of six research areas linking geography and moral philosophy, alongside the historical geography of moralities, inclusion and exclusion in bounded spaces, the moral significance of distance and proximity, questions of social justice and environmental ethics. Smith extends his discussion in Moral geographies (2000a), a wide-ranging treatment of geography, morality, ethics and justice (see also moral landscapes).

The term ‘moral geographies’ achieved prominence within human geography through Driver’s study of allied ‘environmentalism’ and ‘moralism’ in nineteenth-century social scientific urban studies: ‘“Moral science” was . . . a science of conduct and its relationship to environment, both moral and physical’ (Driver, 1988, p. 279). Driver argues that such moral
geographies ‘permitted the birth of social science in England’ (p. 276), the implication being that subsequent academic geographies may also have drawn on moralistic assumptions concerning environment and society. Jackson’s account of the work of the early-twentieth-century CHICAGO SCHOOL of urban sociologists conversely shows how the identification of forms of moral order underlying ‘apparent social disorganization’ (1984, p. 178) may allow a critique of conventional moralistic assumptions concerning life in the modern city. Matless (1994) develops the theme of moral geographies of conduct by considering how the geography of a particular region, the Norfolk Broads in eastern England, can be understood in terms of competing formulations of appropriate behaviour in the landscape. Moral geographies are here constituted through assumptions concerning class and landscape. Such work echoes studies of social exclusion and transgression in highlighting the basis on which people may be labelled as in or out of place feedback.

Some moral geographical work has sought a prescriptive role. Sack (1997) argues for the inherently geographical nature of moral actions in order to develop a framework through which we might improve ourselves as moral geographical subjects: ‘Thinking geographically heightens our moral concerns; it makes clear that moral goals must be set and justified by us in places and as inhabitants of a world’ (p. 24). Sack recognizes the complex variations of morality between different times and places, but the aim, in common with the tenor of much HUMANISTIC GEOGRAPHY, is to seek a normative framework for being human; for being, in Sack’s terms, a ‘geographical self’. For other work noted above, however, the term ‘moral geographies’ is not prescriptive, its use being informed by a philosophical and political assumption that senses of moral order are produced through environmental and spatial practices that are always bound up with relations of POWER. Here, the connection of the moral and the spatial in moral geographies is bound up with a suspicion regarding any claim to be able to define morality, and with a sceptical attitude to the social power of the moral.

MORAL LANDSCAPES

The association of particular LANDSCAPES with schemes of moral value (see also MORAL GEOGRAPHIES). Tuan (1989) reviews the wide-ranging historical and geographical association of particular moral values with the landscapes of city, country and garden. A moral–spatial DIALECTIC may also be identified whereby moral landscapes both reflect and reproduce senses of moral order. Work has focused on such processes in the geography of institutions, in the use of architecture and landscape design to promote particular moral principles, and in the production of consciously ‘alternative’ social spaces.

The institution as moral landscape is considered in Ploszajski’s (1994) work on the Victorian reformatory school as an ‘environment of moral reform’. Such moral landscapes are one element of a geographical interest in relations of SPACE and POWER, whereby spatial organization is shown to be not only reflective of but central to the workings of power. Daniels’ (1982) study of the ‘morality of landscape’ in the work of Georgian landscape gardener Humphry Repton shows how aesthetic values of landscape design were at the same time moral values concerning social harmony, plebeian deference and aristocratic responsibility. The theme of moral landscapes thereby connects to aesthetic, social, political and economic issues: indeed, all of those categories are shown to be mutually constitutive. Pinder’s (2005c) study of utopian URBANISM in the twentieth century similarly draws out the strong senses of moral order informing the modernist urban schemes of architects and planners such as Le Corbusier (see UTOPIA).

Studies of moral landscapes may also address the ways in which moral value is located in particular environments. Matless (1997) considers how moral debates over conduct in open-air landscape shaped cultures of landscape, LEISURE and the BODY in twentieth-century England, and served to reproduce versions of English national IDENTITY. Associations of morality and NATURE, whereby moral order may be equated with a sense of natural order, may also serve to enable particular groups or individuals to claim a moral landscape close to nature. Locating the moral in the natural is a common trope of certain forms of ENVIRONMENTALISM, which cultivate an ecological morality or environmental ethic around an assumed moral community of the human and nonhuman. Such work differs from much of the work discussed above in operating with a strongly normative sense of morality (see also MORAL GEOGRAPHIES). A normative use of the term moral landscape is also found in Ley’s (1993) work on co-operative housing in Canada, presented as embodying moral
principles of community and individuality through an oppositional postmodern architectural style. Other forms of ‘oppositional’ moral landscape might be traced in studies of the geographies of transgression, where landscapes labelled by others as immoral are upheld as pointers towards the production of alternative social space.

morphogenesis (The study of) change in form over time. The term derives from developmental biology, and is sometimes used as a synonym for positive feedback in systems analysis (see also complexity theory). Its most developed use in human geography to date has been in studies of landscape change in historical geography. (See also morphology.)

morphology Form or the study of form. Morphology became a contested term in the struggle between the human geography of Paul Vidal de la Blache and the emerging sociology of Émile Durkheim at the turn of the twentieth century. Durkheim argued that the systematicity of the social – and thus what made its scientific study possible – was the result of its morphology, by which he meant the spatial forms through which individuals were held together as a social structure. For this reason, any account of the constitution of social life would have to include many of the propositions of human geography, which Durkheim regarded as one of the ‘fragmentary sciences’ that had to be drawn out of their isolation to contribute to the plenary social science of sociology (Andrews, 1993). This sense of social morphology can be traced through twentieth-century sociology in the writings of Maurice Halbwachs, Georg Simmel and others, but Vidal complained that Durkheim’s view ignored the physical–ecological dimension and left society suspended in the air.

It was exactly this conjunction between ‘the social’ and ‘the natural’ that prompted Carl Sauer to insist that the morphology of landscape was the central object of geographical enquiry. For Sauer (1963b [1925]), geography was ‘a science that finds its entire field in the landscape on the basis of the significant reality of chorological relation’. Sauer’s conception did not neglect spatial arrangements, in his terms ‘the connections of phenomena’ (as these differed from place to place: see chorology), but his emphasis on morphology derived from J.W. Goethe’s eighteenth-century interest in ‘the science of forms’ and registered two other claims of equal importance:

- ‘Nature’ and ‘Culture’ had to be seen as interdependent in the co-production of landscapes; and
- the same basic forms recurred across the whole field of transformations.

The first of these was focal to Sauer’s sense of historical geography, so that his enquiry was not confined to the morphology of landscape but was directed towards its morphogenesis; that is, the development of its forms over time. It was in this sense that Sauer described ‘all geography [a]s physical geography’: in its focus on physical form, on the material inscriptions of culture on the surface of the Earth. This intersected with his second claim, because he insisted that ‘a definition of landscape as singular, unorganized or unrelated has no scientific value’ and he was concerned to develop a conception of landscape as ‘a generalization derived from the observation of individual scenes’. Much later, others developed this in directions that Sauer refused to take. In particular, some early work in spatial science involved a search for geometrical and mathematical regularities in the evolution of spatial patterns of settlement (see Harvey, 1967). This too can be seen as a revivification of the science of morphology, but it usually acknowledged a debt neither to Goethe nor Sauer but to D’Arcy Thompson’s On growth and form (1922 [1917]) and his pioneering search for ‘essential similarities’ between ‘animate and inanimate things’.

The interest in morphogenesis has continued in both European and American geography. There has been a long-standing interest in the historical evolution of rural landscapes (e.g. Helmfrid, 1961) and urban landscapes (e.g. Conzen, 1960; see Whitehand, 2001). Much of the early work was qualitative and descriptive, but in recent years, and in conjunction with parallel studies in archaeology, there have been considerable advances in the quantitative measurement of landscape forms (metatological analysis), including the integration of space syntax with GIS (Bin Jiang and Claramunt, 2002; Lilley, Lloyd, Trick and Graham, 2005). Urban morphogenesis remains a vital area of geographical enquiry (Vance, 1990).
1996 and publishes a journal devoted to *Urban Morphology*. There has been a particular interest in the *political economy* of urban morphogenesis (Whitehand, 1987), and more recently in the cultural and symbolic dimensions of urban morphology (Lilley, 2004a,b).

Lilley (2004a); Whitehand (2001).

**mortality**  The incidence of death, or rate of dying, in a population. Along with *fertility*, this controls natural increase which, together with *migration*, completes the balancing equation that is used in *demography* to assess population growth, decline and *age composition*. Exploring national and regional variations in crude death rates, infant mortality rates, infanticide and *life expectancy* has increased understandings of epidemiological transitions (Omran, 1983), *uneven development* and gender discrimination (Rafiq, 1991) (see *health geography*; *medical geography*).

**Suggested reading**
Weeks (1999, ch. 4).

**multiculturalism**  An *ideology* and *state policy* that seeks to establish a model of *government* to permit the coexistence of culturally diverse populations. Its distinctive feature is a respect for cultural difference and, in contrast to *assimilation*, support for the maintenance of old-world cultures. While not new, cultural diversity assumes its accentuated current profile from the large movements of documented and undocumented workers from the global South to the depleted *labour markets* of the global North (see *migration*; *north-south*).

Multiculturalism is not an inevitable policy response to cultural diversity; in western *Europe*, while the UK invoked some commitment to multiculturalism, France’s republican model rejected reference to pre-existing immigrant cultures in favour of assimilation to a putatively egalitarian national citizen, while the German tradition of *ius sanguinis*, or ethnic exclusivity (see *ethnicty*), envisaged temporary guest-workers rather than permanent immigrants. The UK, the Netherlands and the Scandinavian states would most readily have described themselves as multicultural nations, though there has been some back-pedalling of late. More complete multicultural commitment occurs in Australia and especially Canada, the only country with a Multiculturalism Act and which includes multicultural *rights* within its constitution.

In an important respect, all states are multicultural inasmuch as they include culturally distinct minorities. But the existence of *demographic multiculturalism* is no basis for assuming that institutional and legal recognition of diversity will occur. A necessary development is, at minimum, a tolerance of ethnic difference, and more positively a respect and welcoming of cultural diversity that may lead to *heritage multiculturalism*, where the state celebrates diversity with grants to permit the expression and survival of folk cultures, including literature, dance and religion. In the USA, the principal manifestation of multiculturalism has been the often controversial use of Spanish as a heritage *language* of instruction in schools in some districts with concentrations of Latino immigrants. But heritage multiculturalism offers no protection of *citizenship rights*, and a more mature development is a *rights-based multiculturalism* that offers legal protection against group-based discrimination, where minorities can claim rights in such fields as anti-*racism*, social service delivery, employment equity, *policing* and *immigration policy*.

Despite its liberal objectives, multiculturalism has attracted considerable criticism. The political right fears the escalation of an *identity* politics that fragments the national project (Huntington, 2004: see also *nation-state*; *nationalism*). The political left, in contrast, challenges the existence of a veil of cultural equality that conceals structures of economic inequality, and suspects that multiculturalism has been co-opted as a vehicle to promote neo-liberal trade and investment (Mitchell, 2004b; see *neo-liberalism*). To this, Ghassan Hage (1998) has charged that multiculturalism in Australia has become a tool of an older white elite to divide new immigrants, thereby maintaining traditional political privileges. But following September 2001 and subsequent *terrorist* attacks in *Europe* and *Asia*, such intellectual challenges have been superseded by a populist and media barrage that has falsely blamed multiculturalism for nurturing hostile criminal and terrorist cells within the matrix of tolerated cultural difference. In the present decade, multiculturalism is a policy forced on the defensive (Joppke, 2004).

**multidimensional scaling** (MDS) Methods for simplifying matrices of distances between a set of points, while as far as possible retaining their relative ordering (i.e. of the distances between the observations). Developed by psychologists for identifying similarities among individuals on a wide range of attitudes (the distances measure how much each pair differs on a set of attitudinal scales), MDS locates the individuals in a smaller number of dimensions than the original scales, so reducing a multidimensional situation to more comprehensible proportions (cf. factor analysis). MDS has been adapted for simplifying maps on the basis of, for example, the time taken to travel between two points rather than the distance between them.

**multilateralism** Foreign policy actions involving agreements, treaties and co-operative actions between more than two states. In contrast to actions by single states (unilateralism) or between two states (bilateralism), multilateralism involves international treaties between many parties or regional agreements between groups of neighbouring states. Multilateralism is often a strategy advocated by medium-sized states hoping to shape international agreements in their favour in the face of the greater power of large states. The term is sometimes used derisively by power brokers in the great powers, and as a term of virtue and aspiration by those anxious to limit the capabilities of great powers to act unilaterally.

But in fact superpowers and great powers frequently use multilateral institutions; indeed, the USA used its power after the Second World War to establish many multilateral institutions, especially through the Bretton Woods financial arrangements and alliances such as the North Atlantic Treaty Organization (NATO), which in turn were useful in the pursuit of its hegemonic international goals (Latham, 1997). Multilateralism is often directly linked to such institutions. Ruggie (1993, p. 14) suggests that the term ‘multilateral’ is best understood as ‘an adjective that modifies the noun “institution.”’ What distinguishes the multilateral form from others is that it coordinates behavior among three or more states on the basis of generalized principles of conduct.’ This suggests that multilateralism is frequently also about building norms or rules that guide state conduct.

Currently, the most high profile multilateral institutions are the United Nations (UN) and the World Trade Organization (WTO), which deals with most international trade in the global economy. Given that these organizations provide legitimacy for states, and act to censure and sanction those that violate the multilateral codes of conduct, great powers frequently use these institutions to justify their actions. The USA’s use of the UN in 1990 and 1991 to justify military intervention in Iraq during the first Gulf War, and the invocation of the alliance commitments under NATO in the aftermath of the terrorist attacks on 11 September 2001, illustrate that multilateralism has many uses even for superpowers.

Multilateralism in European history is usually traced to the ‘Concert of Europe’ arrangements set up after Napoleon’s final defeat in 1815. Designed to produce the peaceful resolution of conflicts, the Concert facilitated diplomatic agreements and, despite notable lapses such as the Franco-Prussian war of 1870–1, managed to maintain relatively peaceful relations between the European powers for a century. This system was shattered by the First World War in 1914 and replaced by the League of Nations, which in turn was replaced in 1945 after the Second World War by the UN in a further attempt to establish a multilateral institution to prevent war between states. The UN now includes all the states in the system as members. Among the multilateral norms that the UN system has established as ground rules for international conduct three are of particular importance: territorial integrity (see territory); non-intervention; and sovereign equality among states (see sovereignty). In combination, these have produced a territorial order of formally sovereign states in the aftermath of the decolonization of the European empires. This multilateral norm has also effectively fixed the boundaries of states, creating a (relative) territorial permanence to the world political map (Zacher, 2001).

Ironically, however, just as state borders are becoming increasingly fixed, and thus a major source of international conflicts is being removed, many major problems are spilling over those borders and require concerted international co-operation. In recent decades, multilateral action by international social movements and campaigns on human rights, global warming and a host of other predicaments confronting what is sometimes described as global civil society have injected
new norms into the international system and thereby added a further dimension to multilateralism (see also COSMOPOLITANISM). Arguments about humanitarian intervention in the face of state failure and environmental disasters have suggested a more activist stance for international institutions in the face of human suffering, and in the process challenged the UN norm of non-intervention. Advocates insist that all states have a responsibility to protect their citizens and that, in extreme cases when they obviously fail to do so, intervention from abroad is justified (International Commission on Intervention and State Sovereignty, 2001): a claim that is controversial precisely because it overrides the territorial integrity principle of the UN. Simultaneously, in the aftermath of 11 September 2001, the Bush administration in the USA frequently preferred to act alone in a unilateral manner, and refused multilateral co-operation on such matters as the International Criminal Court and the Kyoto Protocol on climate change. This stance makes multilateral action more difficult on many issues, and yet, given the increasing number of international agreements on numerous matters, multilateralism as a foreign policy approach has now become a widely accepted and routine diplomatic practice. But in the process territorial sovereignty has become a more fluid principle in INTERNATIONAL RELATIONS (Agnew, 2005b).

MULTI-LEVEL MODELS

Quantitative methods that can analyse research problems with a complex data structure. In a hierarchical structure, the lower-level unit is nested in one and only one unit – for example, people in neighbourhoods in a two-level structure, and people in neighbourhoods in regions in a three-level structure. Other examples are repeated measures of individuals as in a panel study (cf. LONGITUDINAL DATA ANALYSIS) and a multivariate design when there is more than one response variable, so that it is possible to model several aspects of individual behaviour simultaneously. There are two types of non-hierarchical structure. In a cross-classified design, lower units may nest within more than one set of higher-level units, so that pupil performance may be affected by individual, school and neighbourhood characteristics (cf. NEIGHBOURHOOD EFFECT). Both schools and neighbourhoods are higher-level units, but they are not nested within each other. The remaining type is a multiple membership model in which lower-level units are affected by more than one higher-level unit, so that people’s voting behaviour may be affected by the different HOUSEHOLDS and neighbourhoods they have been members of, with a weight proportional to the relative time spent in each. It is possible to combine these structures in a rich fashion, so that spatial MODELS (e.g. GEOGRAPHICALLY WEIGHTED REGRESSION) can have a hierarchical structure in which individuals are affected by the area they live in, and a multiple membership relation by which they are affected by spillover effects from nearby neighbourhoods (see ECOMETRICS).

Such models can handle continuous and CATEGORICAL DATA responses and variables and, indeed, interactions between predictor variables at each level of the structure (cf. MEASUREMENT). In terms of specification, in addition to the usual REGRESSION coefficients that estimate the mean (or fixed) relationship across all structures, there is considerable development of the random stochastic part of the model (see STOCHASTIC PROCESS) so that it is possible to separate between-individual from between-neighbourhood variation and, indeed, to allow a variable to have a differential effect on the outcome in different neighbourhoods. Because of this specification, these are also known as random coefficient or mixed models (fixed and random).

Multi-level models are increasingly being used in social science research, as they have a number of advantages. Technically, they can model complex data dependencies, including spatial and temporal CORRELATION, and thereby give correct standard errors for the fixed estimates; this is particularly important for variables measured at the higher level. They also allow explicit modelling of heteroscedasticity at any level of the model. Substantively, by modelling simultaneously at the micro- and macro-levels, they overcome the atomistic fallacy of modelling individuals and ignoring context, as well as the ECOLOGICAL FALLACY, of not modelling at the individual level. Most importantly, they can incorporate an element of context so that there does not have to be a single relationship fitted for all times and places, so that the class effects on individual voting can be allowed to vary from place to place (Jones, Johnston and Pattie, 1992).

multiple nuclei model  Generalization of the internal structure of cities. The concentric-zone theory is a generalization for all cities. The arrangement of the sectors in the sector theory varies from city to city. The diagram for multiple nuclei represents one possible pattern among innumerable variations (Harris and Ullman, 1959).

multiple nuclei model  A model of intra-urban land-use patterns developed by Chauncy Harris (1914–2003) and Edward Ullman (1912–76: see Harris and Ullman, 1945) that combines and extends the features of the earlier ZONAL MODELS and SECTORAL MODELS of the CHICAGO SCHOOL. Rather than being based on a mono-nuclear city, this model has land-use patterns organized around several nodes (see figure), on the argument that different uses cluster together (in some cases to share specialized facilities) and wish to avoid other uses, thereby creating a number of nuclei around which the city is organized.

multipliers  A measure of the total economic impact of an investment decision, policy change or external ‘shock’. This includes not just the initial, immediate impact, but also the indirect or ‘knock-on’ consequences. Thus a new manufacturing plant creates initial employment; this creates a demand for services in the locality, so triggering other new jobs. The manufacturing expansion also generates demand for additional inputs of energy and steel, so having ripple effects on supplying sectors. Such multiplier effects can be traced using INPUT-OUTPUT models. There is also a need to track the geography of these multiplier effects, to see what ‘leaks’ from the local economy into other regions, and estimating spatial multipliers undertaken in SPATIAL ECONOMETRICS. music  Although GEOGRAPHY has often been dominated by visual means of REPRESENTATION, the study of music, and indeed sound more generally, has a long if discontinuous history within the discipline.
work is probably that by the Finnish geographer J.G. Grano¨, whose studies of sonic landscapes in Finland date back to 1929 (see Grano¨, 1997 [1929]). However, evidence of a concerted interest in either music or sound does not exist until the early 1970s. Studies influenced by the Berkeley school of cultural geography examined musical performances, music association memberships, musical listening and musicians’ birthplaces alongside a variety of other cultural artefacts. The purpose was to identify cultural hearths and trace diffusions across space and through hierarchies, mapping out culture areas, regions and landscapes. This traditional approach to the geography of music is exemplified in Carney (2003). Early studies focused substantially on rural folk cultures and regional styles in the USA. More recently, the focus has switched to consider how popular musical genres such as those based in Nashville, Seattle or Liverpool evolve within a given place (Carney, 2003, pp. 1–2).

Geographical studies of music have proliferated since the mid-1990s. Developing themes and methods from the cultural turn, studies have examined issues concerned with sense of place, belonging, gender, style and identity, the politics of landscape representation, and national and transnational identities (Leyshon, Matless and Revill, 1998; Brunn and Waterman, 2006). One theoretical starting point was the concept of ‘soundscapes’ adopted by S.J. Smith (1994b) to bring out the inherently spatial aspects of auditory environments. However, many of these studies drew substantially from theoretical developments in related disciplines. From sociology, for instance, these include the functioning of institutions and organizations in the production and consumption of music and the role of sound in the fabric of everyday life; from cultural studies/anthropology, the place of music in politics of cultural hybridity, subaltern groups and alternate lifestyles; and from critical musicology, the social production of musical experience and critiques of conventional conceptions of popular and elite, worthy and worthless musics. The rise to prominence of culture industries as a vehicle for economic regeneration has provided further impetus, resulting in studies centred on the merits of cultural policy, cultural quarters, cultural tourism, creative capital and festivals, as well as local and regional place marketing. The context of new digital and networked communications media has produced studies grounded in new economic geography primarily concerned with media synergies and with global, regional and local networks of production and marketing (Connell and Gibson, 2002).

Recent work often critiques the new cultural geography’s apparent preoccupation with text and representation. Although music can be considered a material artwork like painting or literature, the ephemeral qualities of sound make music a distinctively performative cultural medium. As geographers have engaged with art forms beyond their conventional concern for the visual, so the performative aspects of music and dance have become an increasing focus of study. Investigations of affect and emotional geography have resulted in studies centred on listening practices, performing and making music, rhythm, embodiment and the dancing body. Much of this work explores both the subjective experience of music and its physical presence as it is embodied in objects such as instruments, recordings and sheet music; their associated organizations and infrastructures, venues, recording companies and radio stations; and the practices of performing and listening. Concerns for the co-construction of nature and the materiality of cultural life now produce studies that explore the multi-sensory richness of environmental experience whilst remaining sensitive to both the phenomenology and cultural politics of sound (Anderson, Morton and Revill, 2005). Such studies connect environmental history and ecology with a critical interrogation of regional and local cultures, in ways that acknowledge the pioneering work of Grano’s early sonic geographies.
narco-capitalism  It is almost impossible to assess the gross value of the global illegal drug trade – a worldwide black market in the production, processing, distribution and retailing of illegal psychoactive substances. According to the United Nations World Drug Report in 2006, the retail value of illegal drugs (including drugs seized) was $322 billion. Other sources estimate the total figure to be well in excess of $400 billion. The trans-border trade typically links – consistent with a much longer history of the drugging of the First World by the Third – impoverished producer states (Afghanistan, Colombia) with transatlantic economy consumers. The consumption of illegal drugs is, however, a global phenomenon (200 million people between 15 and 64 years have consumed some type of illegal drug in the past 12 months, according to the UN Drug Report in 2006). Illicit drugs are as central to the slum world of Rio and Jakarta as they are in the white-collar Wall Street and American ghettos. The massive scale of the drug business and the direct (and complex) actors in the cocaine or heroin global commodity chain – the peasant producers, the local processors, the middlemen, the whole-salers, the mules, the drug cartels, corrupt military and state security apparatuses and so on – can only be grasped as a particular sort of market – albeit exceptionally violent, well-policed, often quite competitive, and of course illegal. Narco-capitalism refers to the structure and organization of the production, distribution and sale of illegal drugs, understood as a system for the production of profit; that is to say, a global system of accumulation not unlike other drugs (sugar, coffee).

It is commonplace to assume that the key illegal drugs – especially in trans-border activity – are cocaine, heroin and cannabis, but narco-capitalism also includes the illegal sale of legal drugs (tobacco, for example, is often smuggled across borders, taking advantage of differential tax and tariff systems, while some prescription drugs may be available through illegal networks, thereby eliminating the need to manufacture and process the drugs). Some forms of narco-capitalism – the industrial manufacture of LSD or methadone – may be largely national or local in organization. The proliferation of small-scale marijuana production systems under hydroponic conditions may lend itself in particular to local urban markets in the same way that some centres of cannabis production (northern California; Vancouver, BC) may supply regional rather than international demand. Narco-capitalism for hard drugs such as cocaine, ecstasy, meth and heroin has a number of structural features that are especially important in understanding the dynamics of the industry. First, a number of key cartels – Cali and Medellin in Colombia, Juarez and Sonora in Mexico and Puerto Rico – are often linked through a syndicate-like organizational structure (e.g. the Mexican cartels typically traffic drugs provided by the larger Colombian cartels). Second, the cartels cannot operate without the complicity and active co-operation of corrupt governments and militaries that facilitate the transit operations by ‘mules’ (carriers).

To the extent that cocaine is representative of narco-capitalism in general (80 per cent of all cocaine is consumed in the USA), there have been no large US cartels discovered, and much of the drug profit is not returned to Latin America but stays in the USA, where it is laundered for other business operations. A number of corrupt and often military Third World states have become key actors in the global narco-capitalism system (e.g. Nigeria and Panama). What are called ‘failed’ or ‘rogue’ states are often the pillars for the world drug business. As a particular form of capitalism, the narco-economy has two organizational forms: the spoke-and-hub model, in which a combination of violence and relations of trust draw together a central cartel and dispersed gangs and mafia-like organizations; and a vertically integrated ‘corporate’ form of narco-capitalism, in which the cartel controls and orchestrates the entire commodity chain through a system of force and consent, for which the Mafia may be an organizational model (and to which the drug business is in any case organically linked).

nation  A product of nationalism, the nation is nevertheless treated by nationalists
as the naturalized geo-historical foundation for national community. Such foundational thinking often uses geography, and in particular imaginative geographies of place and landscape, to create and consolidate conceptions of primordial nationhood. Sometimes such imaginative geographies of the nation space can also be violently exclusionary, based on racist, ethnicist and/or masculinist phobias about keeping the nation pure by hardening borders (Gilroy, 1987; Theweleit, 1987; Parker, Russo, Sommer and Yaeger, 1992; Radcliffe, 1998; Gallaher, 2003; Flint and Fallah, 2004; Mayer, 2004). At other times, formal spatial depictions of the nation operate more subtly to encode and normalize the political geography of the nation-state as it relates to international and subnational governmental practices (Schulten, 2001; Anderson, 2006a; Flint and Taylor, 2007 [1985]). And in yet other anti-colonial cases of nations without states, or with states that have been repeatedly undermined by colonialism and neo-colonialism, imaginative geographies of the nation serve to keep alive hopes of a future national state free from occupation and external control (Gregory, 1994; Guibernau, 1999). In all these cases, innumerable geographical representations from official maps to landscape depictions to monumental architecture can be drawn upon to affirm and/or question notions of national identity.

In theoretical work that is less attuned to geography, the division of the world map into a series of parcels defined by a standardized nation form tends to be ascribed to more generalized social dynamics. Conservative theorists have tended to fall back on essentializing ideas about ethno-linguistic homelands (e.g. Huntington, 2004; see also Kedourie, 1960). By contrast, liberal theorists have tended to explain the abstract nation form in terms of either the global march of modernity (Gellner, 1983) or the formation of the modern nation-state as a monopolist of administrative information and, in Weberian terms, the so-called legitimate use of violence (Giddens, 1985). Subsequently, post-colonial reflections on global struggles against illegitimate imperial violence have displaced the eurocentrism of the liberal accounts, all the while arguing – as in one famous case – that the assumption of a coherent nation form in the former colonies remains a ‘derivative discourse’ shaped as much by the performance of European nationalist norms as by the cultural complexities of the colonies themselves (Chatterjee, 1986; see also Amin, 1987). Chatterjee advances his arguments by noting the hybridity of the historical record, but by focusing on the past, his derivative discourse thesis fails to explain how the nation form may be challenged and hybridized by extra-national flows in present and future historical moments. By contrast, Marxist accounts, with their attention to the changing scale of capitalism’s organization (e.g. Harvey, 1999 [1984]), and Foucauldian accounts, with their interest in the epistemic enframing of the nation as a container for ‘the economy’ amidst twentieth-century fordism (e.g. Mitchell, 1998), seem better placed to theorize the historical contingency of the nation form alongside its discursive performance. This does not mean explaining the nation in economic terms alone. As Marxist philosopher Etienne Balibar emphasizes: ‘It is quite impossible to ‘deduce’ the nation form from capitalist relations of production’ (1991, p. 89). But it does mean coming to terms with the overdetermination of the nation as part of modern twentieth-century nation-states that were once territorialized but which now seem increasingly re-territorialized amidst the political geographical tensions of global capitalism (Sparke, 2005). To ignore such changes and to continue to examine global politics with a methodological nationalism that treats the nation as a universal norm is to fall into what Agnew calls the ‘territorial trap’ (Agnew, 2003a) – a trap that exists in the first place because of ignorance of the geographical processes and representations through which nations are constructed. MS

National parks The first national park was created at Yellowstone in Wyoming, USA, in 1872, although the Yosemite Valley in California (made a national park in 1890), had been a state park since 1864, and the idea of a national park was first expressed in the USA by George Catlin in 1832. The first US national parks were proposed as a way to protect the sublime and monumental landscapes of the American West, and as a reaction to the threat of the closing ‘frontier’ and the pioneering spirit as a formative element in the American character (Nash, 1982 [1967]). The US model of national parks was built on a conception of nature as wilderness, pristine, separate and separable from human-transformed lands (Cronon, 1995). Yet in national parks, wilderness was created by the deliberate actions of the state, often involving military action: the US Army managed Yellowstone until 1918. The presence of
indigenous people in these areas was systematically ignored. The same process of physical clearance and conceptual deletion of previous human presence accompanied the extension of the Yellowstone model outside the USA. It was soon copied in the British Dominions (Canada 1887, Australia 1891 and New Zealand 1894) and in colonial possessions in AFRICA (the Belgian Congo in 1925, South Africa in 1926). Following the Second World War, the model was adopted in East Africa, ASIA and eventually globally as the international CONSERVATION movement grew (Adams, 2004). The International Union for the Conservation of Nature and Natural Resources (IUCN) established a Provisional Committee on National Parks in 1958, now the World Commission on Protected Areas (www.iucn.org/themes/wcpa). The United Nations adopted a ‘World List of National Parks and Equivalent Reserves’ in 1962, and IUCN defined a series of protected area categories, of which US-style National Parks are widely regarded as the most important (www.unep-wcmc.org/protected_areas/categories/). The global protected area network expanded rapidly. By 2005, there were over 100,000 protected areas covering over 2 million square kilometres, more than 12 per cent of the Earth’s land surface.

National parks created internationally on the Yellowstone model are imagined as places free from human settlement. Their creation has therefore often caused displacement of indigenous or other peoples, either through restrictions on access to land and RESOURCES (including cultural sites) or direct forced resettlement. Globally, there has been a persistent failure to recognize historic human occupation of and RIGHTS to land placed within national parks, or to recognize the extent of human modification of ‘wilderness’ (Neumann, 2004b). Partly because of opposition to such imposed parks, there has been significant emphasis in international conservation policy on ‘community-based conservation’ and ‘park outreach projects’ that seek to create local political and economic support for parks (Hulme and Murphree, 2001). There are also alternatives to the exclusive national park model; for example, British National Parks and French Parcs Régionaux, which are essentially planning designations to preserve the quality of privately owned land.

**nationalism**  A name for the modern social and political formations that draw together feelings of belonging, solidarity and identification between national citizens and the TERRITORY imagined as their collective national homeland. The existence and coherence of a particular NATION is in this sense best understood as an ongoing product and not the primordial precursor of nationalism. But while nationalism can therefore be said to make nations, they are neither illusions nor invented like works of fiction. Although Benedict Anderson’s phrase ‘imagined communities’ has sometimes been misinterpreted as suggesting such an inventive account, in fact, his emphasis on the politically and socially constructive work of nationalism in producing nations is the heart of his much-reprinted book (2006). Nations are imagined, he argues, because nationalism mobilizes a strong but abstract sense of COMMUNITY between distant strangers in a way that consolidates their identification with both a common historical inheritance and a shared national space. This is also why nationalism is more social than the personal passions of patriotism and less legal than the regulative norms of CITIZENSHIP, even though – as feminist and queer geographers in particular have underlined – it is clearly interwoven with each (see Bell and Binnie, 2000; Marston, 1990; see also FEMINIST GEOGRAPHIES).

In the most recent edition of his book, Anderson reviews its many translations and globe-trotting travels, further documenting how nationalism clearly fosters distinct national cultures of reading, writing, teaching and communication. He underlines too that one of his initial intentions in the book (and one that he thinks accounts for much of its global popularity) is that it shifted the geographical focus of the study of nationalism away from EUROPE (and the EUROCENTRISMSM that traditional Marxist accounts shared with traditional liberal accounts) and towards various post-colonial nationalisms of the global SOUTH, including not least of all what he calls the ‘creole nationalisms’ of the Americas (a formulation that itself also usefully undermines exceptionalist American arguments about US republicanism as the uniquely pioneering prototype of post-colonial nationalism). In making this case, however, Anderson does not directly address the many ways in which his arguments have both resonated with and been advanced by various versions of post-colonial theory (see POST-COLONIALISM). His own attention to the role of MAPS and other geographical depictions in imagining the communities of nationalism clearly resonates, for example, with Edward Said’s theoretical
concerns with the imaginative geographies of orientalism; one connection being the ways in which the cultures of imperialism worked contrapuntally to construct the modernity of Euro-American nationalism by constantly contrasting the supposedly pre-modern human geographies of their colonies with the ordered and enframed landscapes of metropolitan museums, exhibitions and textbook cartographies (Said, 1993, 2003 [1978]; cf. Mitchell, 1988; Gregory, 1994). Other post-colonial studies of nationalism have advanced these ideas by problematizing the diverse geographical arguments and assumptions that continue to create hierarchies of national belonging, national achievement and national blame in the course of imagining community. Whether it is concerned with the fate of women on the margins of the post-colonial nation (Spivak, 1992), or interest in the necessarily extra-territorial affiliations of anti-racist and anti-colonial activists (Gilroy, 1993; Singh, 2004), or reflection on the historical tragedies that have led to geographies of blame for the so-called failure of post-colonial nationalism in countries such as Haiti (Scott, 2004; see also Farmer, 1992), scholarship addressing the imagined communities of nationalism has increasingly also complicated pre-emptive epit-stemological assumptions that limit national history to national geography. At the same time, work on the ways in which national geography is taught and learned in nationalist teachings themselves has also increasingly sought to unpack how the performance of nationalism can both close down and open up opportunities for imagining territory anew (compare Bhabha, 1994 with Brückner, 1999; Schulten, 2001; Sparke, 2005). All these post-colonial questions indicate how nationalism can be implicated in racialized imaginings of space and place in both dominant and resistant ways, an ambivalence that has historically been one of the reasons why defining nationalism has been so vexing for critical theorists. As Etienne Balibar puts it, with both a question and an answer of his own:

Why does it prove to be so difficult to define nationalism? First, because the concept never functions alone, but is always part of a chain in which it is both a central and weak link. This chain is constantly being enriched… with new intermediate or extreme terms: civic spirit, patriotism, populism, ethnicism, ethnocentrism, xenophobia, chauvinism, imperialism, jingoism… (1991, p. 46)

**nation-state** The combination of national governance and national governmentality that emerged as the norm of European state-making in the eighteenth and nineteenth centuries, and that spread across the world in the twentieth century as a basis for post-colonial state-making in the former colonies of the global South. In all these contexts, the hyphen in nation-state has traditionally symbolized the articulation of nationalism with the development of the modern state, its sovereignty over territory, and its capacity to police and administer the spaces contained by national borders (Giddens, 1985; Sparke, 2005). None of these articulations have ever been comprehensive and complete, and while most nation-states presume to govern all inhabitants as if they were a single nation, in practice they often also dominate and marginalize populations who speak minority languages, identify with minority ethnic communities and/or who live in borderlands (Flint and Taylor, 2007 [1985]). Thus while the hyphen in nation-state is considered a conventional and quite unremarkable linguistic convention, it points to social and political practices that often put an oppressive line through the possibility of statehood for ‘subnational’ nations.

The volatile and often violent two-way geographical dynamic between state-making and nationhood only really became stabilized in the mid-twentieth century, at the same time as it was extended through anti-imperial independence movements across much of the world (Blaut, 1987). At this point, Fordist regimes of accumulation in core countries of the world economy tended to systematize ‘official nationalism’ as a basis for managing class divisions through redistributive taxation, state education and welfare administration (see Fordism). And in the global south, nationalism meanwhile served to rally popular support for new post-colonial development initiatives based on import substitution – albeit ironically also sometimes being twisted into neo-imperial projects of quelling the resistance of unofficial nationalism (Trouillot, 1990). But even at this high point of the nation-state as a container of politics, the hyphenated hybrid was wrecked by the geopolitical tensions of the cold war and global uneven development (Taylor, 1994a). Even the institutions of international relations where nation-states were supposedly represented in their full normative and sovereign roles simultaneously revealed their precariousness: the United Nations was
famously described in 1977, for example, as ‘little more than the meeting place for representatives of disunited states’ (Seton-Watson, 1977). It is scarcely surprising, therefore, that today, while we have by no means arrived at the end of the nation-state, as business-class globalists advertise (e.g. Ohmae, 1995), we are seeing nation and state being pulled apart in the context of recent rounds of GLOBALIZATION.

Macro forms of state-making are increasingly becoming transnational in their scale of organization in concert with the entrenchment of NEO-LIBERALISM as the dominant free-market model of governance (Peet, 2003; Harvey, 2005). Meanwhile, micro models of neo-liberal GOVERNMENTALITY that promote entrepreneurial forms of SUBJECTIVITY and benchmarking approaches to place-making come together in context-contingent ways with global market forces to create new ASSEMBLAGES of IDENTITY, affiliation and CITIZENSHIP that are no longer so clearly bound-up in the nation-state (Mitchell, 2004a; Ong and Collier, 2005). If the nation-state is not dead, it is clear that it is being remade in different ways in different places by both roll-out and roll-back forms of neo-liberalism; it is becoming redefined as the managed mediator of neo-liberal HEGEMONY (Peck and Tickell, 2002): on the one hand, a relentless enforcer of free trade rules and neo-liberal GOVERNANCE in arenas ranging from land management to regional development to workfare to the warfare of the coalition of the billing; and, on the other hand, a bulwark of the status quo and an excuse for business as usual when non-neo-liberal visions of development, debt relief, women’s RIGHTS and environmental protection are proposed at transnational and subnational scales (Public Citizen, 2007). Meanwhile, social relations and identifications are themselves also becoming remade and re-territorialized by the globalizing forces. The accelerated FLOWS of tourists, migrants, money, information, movies, sports and news programmes are challenging the old print MEDIA of national consciousness, and turning the hyphen in nation-state into more of an index of disjunction (Appadurai, 1996). All these changes have not (notwithstanding Hardt and Negri, 2000) led to the complete eclipse of the nation-state by a new global empire, but they have led to the withering of the national state as an institutional enabler of national DEMOCRACY, and they have therefore made the search for new transnational convergence spaces for of democracy all the more urgent (Routledge, 2003: see also TRANS-NATIONALISM).

natural resources Conventionally, this term refers to biophysical materials that satisfy human wants and provide direct inputs to human well-being. The term may, however, be defined more broadly to include any component of the non-human world that performs a socially valuable function. Natural resources are the product of geological, hydrological and biological processes: the adjective ‘natural’ denotes this location anterior to human labour. It is for this reason that classical POLITICAL ECONOMY described as ‘gifts of NATURE’ the raw materials and productive energies of the non-human world.

A distinctive vocabulary is available for differentiating the qualities and properties of a vast range of natural resources. A primary distinction is between exhaustible (stock) and renewable (flow) resources, based on the potential of different biophysical materials to regenerate (see figure). For stock resources, a secondary distinction is between materials that are consumed by use and cannot be recovered (such as fuels) and those that may be recycled (most applications of metals). Flow resources may be subdivided according to whether use of the resource subtracts from the amount and/or quality of the resource base: for so-called ambient resources, use of the resource degrades neither the amount nor quality (e.g. solar radiation, wind, waves). For other flow resources, there is a threshold beyond which further consumption exceeds the capacity of the resource to regenerate: these ‘critical zone’ resources can be ‘mined’ to depletion/extinction (e.g. ground water, fish, game species). Basic distinctions such as these have underpinned the development of different MODELS for managing renewable and non-renewable resources (see RESOURCE MANAGEMENT). Recent developments in the biological sciences and the so-called ‘NEW ECOLOGY’, however, have thrown into question many of the assumptions that underlie these models, and have drawn attention to the non-linear behaviour of many ecological SYSTEMS and their capacity for ‘surprise’ (Botkin, 1990). At the same time, ENVIRONMENTAL ECONOMICS has re-framed many of the questions surrounding natural resources in terms of the management of ‘ecological capital,’ a new vocabulary that facilitates the commensurability of the non-human world.

From both an historical and a philosophical perspective, ‘natural resources’ are a significant misnomer. First, the practices of EXPLORATION, SURVEYING, MEASUREMENT and experimentation by which natural resources come to be known
natural resources (‘discovered’) highlight their deeply social origins. Second, resources are a dynamic category: different parts of the non-human world slip into (uranium, coltan) and out of (alum, flint, osiers, guano) this category across time and place (see resources). The remarkable history of natural gas, for example, demonstrates how a single substance may be considered as variously hazardous waste, ‘neutral stuff’ or a valuable natural resource, depending on knowledge, price, social norms and expectations (regarding pollution), and the availability of alternatives. GEOGRAPHY continues to make contributions to the practical art and science of managing natural resources, but there is also a robust tradition of critical enquiry that acknowledges how ‘natural resources are not naturally resources’ (Hudson, 2001).

Suggested reading Bakker and Bridge (2006); Rees (1991).

naturalism Apart from the denial of the existence of God or the rejection of the Cartesian dualism of mind and body, the term ‘naturalism’ is nowadays commonly used to mark one’s acceptance of a scientific philosophy (see philosophy; science). An overwhelming majority of Anglo-American philosophers claim to subscribe to some form of naturalism. From the vantage point of contemporary philosophy, naturalism is the twofold view that: (1) everything is composed of natural entities – those studied in science – whose properties determine the properties of things, including persons and abstract mathematical objects; and (2) that science consists essentially in the registration of (or refutation of claims about) empirical invariances between discrete events, states of affairs and the like. This view, which can be aptly termed ‘scientific naturalism’, argues the strong claim that natural science provides a true or essential picture of nature. More contentious versions of scientific naturalism or scientism assert that it is the only true picture. Thus, in the words of Wilfred Sellars, ‘science is the measure of all things, of what is that it is, of what is not that it is not’ (1963, p. 173). Scientific naturalism contends that the great successes of the modern natural sciences in predicting, controlling and explaining natural phenomena – mathematical physics and Darwin’s theory of evolution are exemplars – imply that the natural sciences’ conception of nature is very likely to be true and, moreover, that this is our only bona fide or unproblematic conception of nature.

Importantly, scientific naturalism rejects any goal of First Philosophy – which claims, as in Cartesian or Kantian thought, to provide the epistemological and metaphysical foundations for the natural sciences. Instead, scientific naturalism takes the resolutely Human stance that the human is simply a part of nature, not set over against it. This in turn denies the possibility of a First Philosophy prior to the natural sciences, such that philosophy can no longer claim to be the master discipline that sits in judgment over the claims of natural sciences or supplies the foundations for their operation. Instead, philosophy is
rendered continuous with science: it is science in its general and abstract reaches. A further implication for the social sciences is an essential unity of method with the natural sciences and, in some formulations, an actual identity of subject matter as well.

The philosopher Roy Bhaskar, whose work has been influential for several radical geographers, counterposes ‘critical naturalism’ to scientific naturalism and its thesis of continuity between the social and natural sciences. He instead asserts that ‘ontological, epistemological and relational considerations all place limits on the possibility of naturalism (or rather, qualify the form it must take); and that these considerations all carry methodological import’ (1998 [1979], p. 3; author’s italics). Thus, Bhaskar denies that natural and social objects are alike in their make-up; rejects empirical realism (Humean epistemology) in favour of transcendental or critical realism as the protocol of knowledge more appropriate to the human sciences; and offers Marx’s analysis in Capital as paradigmatic of a substantive use of this transcendental procedure (see REALISM).

Baruch Spinoza’s naturalism is worth a mention, given his current resurgence within human geography and allied fields. While the renewal proximately derives from studies on Spinoza by scholars such as Gilles Deleuze, Antonio Negri, Genevieve Lloyd and Louis Althusser, their wide uptake by human geographers suggests a desire for an ethics and politics of interaction rooted in an immanentist ontology – that is to say, an affirmative ontology of connections between human and non-human entities that (a) denies any prior separation of nature and society, (b) rejects any form of transcendence (God or otherwise) as source of an authorizing design or telos for society, and (c) maintains that combinations of bodies are all there is, and our ethical-political task is to dare to strive for sameness in ways unknown.

**nature** A term with three main meanings:

- the essence or defining property of something;
- a material realm untouched by human activity; and
- the entire living world, of which the human species is a part.

These meanings often overlap and are sometimes contradictory. They are used in, and reproduced through, everyday speech as well as artistic and scientific discourses. This multivalency led the cultural critic Raymond Williams to observe that ‘nature is perhaps the most complex word in the [English] language’ (1983 [1976], p. 221) and that a history of its changing use would amount to a history of a large part of human thought (ibid., p. 225). Something of these complexities and histories can be glimpsed by juxtaposing two Anglo-Western attitudes to nature that are 300 years apart. The leading British political commentator John Locke, writing in the late seventeenth century, as the European settlement of North America got under way, made the following observation:

In the first ages of the world men were more in danger to be lost, by wandering from their company, in the then vast wilderness of the earth, than to be straitened for want of room to plant in. And the same measure may be allowed still without prejudice to anybody, as full as the world seems. (Locke, 1988 [1690], p. 294)

Writing in the late twentieth century, as climate change entered global public consciousness, the North American environmental observer Bill McKibben articulates a very different vision:

An idea, a relationship, can go extinct just like an animal or a plant. The idea in this case is ‘nature’, the separate and wild province, the world apart from man. […] By changing the weather, we make every spot on earth man-made and artificial. We have deprived nature of its independence and that is fatal to its meaning. (McKibben, 1990, pp. 48 and 58)

As both of these accounts suggest, there is a powerful geographical imaginary associated with the idea of nature, particularly with the second of the three meanings identified above. This geographical imaginary translates the categorical opposition between things attributable to nature and those attributable to human society into a spatial purification, in which nature is understood as a pristine wilderness – a space-time outside or before the presence (or taint) of human settlement or activity (Cronon, 1995). It is an imaginary with very real consequences as it is taken up and reproduced through scientific, political and legal practices (Delaney, 2003).
Alongside SPACE and PLACE, the question of nature is one of the most central and enduring of geographical concerns (Fitzsimmons, 1989). As every undergraduate knows, geography stakes its disciplinary identity on being uniquely concerned with the interface between natural environments and human cultures. Nowhere is this better epitomized than in the work of Carl Ortwin Sauer in the 1920s and the legacy of the BERKELEY SCHOOL, with its emphasis on CULTURAL LANDSCAPE in which ‘culture is the agent [and] the natural area the medium’ (Sauer, 1963b [1925], p. 343). However, even here, it is evident that this definitive geographical concern has tended to be cast in terms that engage the world as if it were already divided up into things belonging either to nature or to CULTURE, a division entrenched in the very fabric of the discipline and reinforced by the sometimes faltering conversation between human and physical geographers (see GEOGRAPHY; PHYSICAL GEOGRAPHY).

In consequence, as human geographers set about trafficking between nature and culture, a fundamental asymmetry in the treatment of things assigned to these categories has been smuggled in to the enterprise. Geographies, like histories, become stories of exclusively human achievement played out over, and through, a seemingly indifferent medium of matter and objects made up of everything else. Such stories percolate through diverse currents in HUMAN GEOGRAPHY. These include MARXIST accounts which advance the apparently contradictory idea of the 'PRODUCTION OF NATURE', arguing that more and more of the things we are accustomed to think of as natural – from RESOURCES to LANDSCAPES – have increasingly become refashioned as the products of human labour (e.g. Mitchell, 1996; Gandy, 2002). Such accounts identify this intensifying social capacity to produce nature as second nature, a distinct phase in the historical development of nature–culture relations that supersedes its original or 'God-given' state – first nature (Smith, 1990). Equally, they include cultural accounts that explore POSTMODERN theories to understand better the ways in which our ways of seeing nature are always mediated and shaped by representational practices and devices – from cartographic surveys to wildlife film-making (e.g. Wilson, 1992). These accounts emphasize the politics of REPRESENTATION, recognizing that representational processes are instrumental in constituting our sense of what the natural world is like, rather than merely a mirror image of a fixed external reality. In consequence, such accounts suggest, multiple and often incompatibly representations of the same natural phenomena or event can and do coexist (e.g. Cosgrove and Daniels, 1988).

Whether their emphasis has been on nature’s material transformation or on its changing meaning, these are geographies whose only subject or active inhabitants are people, while everything else is consigned to nature and becomes putty in our hands. In this, human geography’s long march from ENVIRONMENTAL DETERMINISM to SOCIAL CONSTRUCTIONISM seems to have brought us to the same place as that identified by the environmentalist Bill McKibben as the ‘end of nature’ (see Castree, 2005a). This humanist stance is premised on two working assumptions (see HUMANISM). The first is that the collective ‘us’ of human society is somehow always already removed from the rest of the world, for only by placing it a priori at a distance can human society be (re)connected to everything else on such asymmetrical terms as those between producer and product, or viewer and view (Ingold, 2000). The second is that in different ways the generative energies of the Earth itself, in rivers, soils, weather and oceans and the living plants and creatures assigned to ‘nature’, are effectively evacuated from the terms of these analyses (Haraway, 1991c). Such assumptions do not square with the anguish and infrastructure of existential concern that characterize the twenty-first century. In unimaginable and unforeseen ways, the forcefulness of all manner of things has come to make itself felt in our social lives and political agendas. From climate change to mad cow disease, there is a growing sense that our worldly interactions with, and indifference to, more-than-human forces and entities are returning to haunt us. Since the last edition of this Dictionary was published (2000), a major thrust of work in human, particularly cultural, geography has been to challenge these premises and rethink the ‘human’, and the status of the ‘non-human’, in the fabric of human geography (Whatmore, 2002b).

Much of this work has drawn inspiration from POST-STRUCTURALIST philosophies relatively new to geography, through intermediaries such as science and technology studies (STS) (see Hinchliffe, 2007). The argument advanced here is that what we are experiencing is less a ‘crisis of nature’ and more a ‘crisis of OBJECTIVITY’, in which the things ascribed to nature are refusing to stay passively in their boxes and are assuming their irrepressible part in the possibilities and achievements of

493
NEIGHBOURHOOD

social agency that had been falsely ascribed exclusively to humans (Latour, 2004, p. 21). Taking up this argument, human geographers have been exploring the intricate and dynamic ways in which people, technologies, organisms and geophysical processes are woven together in the making and remaking of spaces, places and landscapes. Three of the most important currents in recent work in this vein have been those addressing post-colonial, animal and bodily refiramings of what matters, what must be taken into account, in the making of human geographies.

The first current is concerned with showing that the idea of nature as a pristine space outside society is an historical fallacy. This idea is so pervasive today that it is difficult for many of us to recognize it as a particular and contestable way of seeing the world. A specific concern has been to expose the ways in which the presence of native peoples was actively erased from the landscapes that came to be seen as wilderness in colonial European eyes (see COLONIALISM), and that are now revered by many environmentalists as remnants of ‘pristine’ nature (e.g. Braun, 2002). The second current extends this historical repudiation of the separation of human society and the natural world by paying close attention to the mixed-up mobile lives of people, plants and animals in everyday life time out of mind. Here, ANIMALS have become a vehicle for opening up the ways in which non-human creatures have long been caught up in all manner of social networks, from farming to wildlife, in ways that disconcert our assumptions about their, and our, ‘natural’ place in the world. The third, and perhaps most provocative, current of work in this vein explores the bodily as an important site for geographical research in which the human, quite as much as the non-human, is molten in the heat of technological achievements that recombine the qualities associated with these categories in new forms ranging from transgenic organisms to bionic enhancements (e.g. Thrift, 2005a: see also BODY; CYBORG).

Neighbourhood An urban area dominated by residential uses. While no fixed SCALE can be assigned, neighbourhoods have traditionally been understood to be relatively small or walkable, although they may vary considerably in terms of population (Martin, 2003). Neighbourhood has long been conflated with the notion of COMMUNITY as described in the work of the CHICAGO SCHOOL sociologists. Neighbourhood is the more explicitly territorial concept of the two. Efforts at defining and using the term ‘neighbourhood’ fall roughly into four areas: typologies (identifying primary neighbourhood characteristics); neighbourhood change; neighbourhood effects; and as a territory for political action (Martin, 2003).

Typologies of neighbourhoods draw upon and also echo the conflation with community in the Chicago School approach. These combine physical and social features of TERRITORIES within cities in order to classify each area as some type (Hunter, 1979). The features included in such typologies include RACE and ETHNICITY, RELIGION, family status, and CLASS of the area population, housing tenure, age and other INFRASTRUCTURE characteristics. Neighbourhood types can then be correlated with NEIGHBOURHOOD CHANGE over time, drawing upon the notion of MOBILITY associated with the Chicago School and from INVASION AND SUCCESSION.

Neighbourhood Change focuses on both population and INFRASTRUCTURE. Population may change by one or more measures (such as dominant ethnicity or household structure) due to residential mobility (where people move to a different area within a CITY or a different location entirely). A neighbourhood’s physical INFRASTRUCTURE changes due to decline (due to age or active disinvestment) or renewed investment (as with URBAN RENEWAL or GENTRIFICATION).

‘NEIGHBOURHOOD EFFECTS’ approaches investigate neighbourhoods as loci of social norms that shape individual attitudes, experiences and health (Hunter, 1979; Ellaway, Macintyre and Kearns, 2001). This literature seeks to link individual outcomes with local social and physical conditions. For example, Ellaway, Macintyre and Kearns (2001) found that individuals perceive their HEALTH differently depending upon physical conditions of the neighbourhood. However, Mandanipour, Cars and Allen (2000) argued that structural exclusions of the poor (e.g. uneven access to RESOURCES, due to SEGREGATION) are more powerful forces in an individual’s life chances than local cultural factors.

An approach that highlights the contingency of any definition of neighbourhood upon local context and/or scholarly purpose is that of conceptualizing NEIGHBOURHOOD AS A TERRITORY FOR POLITICAL ACTION (Martin, 2003). In this conceptualization, neighbourhoods are constituted by practice: daily life and particular social and political claims, which are dynamic over time and space. The particular meaning of neighbourhood – as a social community or
historical district, for example – will be articulated and deployed according to the people involved and issues at stake. As the other three approaches suggest, ‘neighbourhood’ is a term that is highly dependent upon the particular location in which it is embedded, the local political and social culture, and the perspective of the individual experiencing or observing the neighbourhood.

Suggested reading

**neighbourhood effect** A type of contextual effect whereby the characteristics of people’s local social milieux influence the ways in which they think and act. Neighbours present individuals with models of attitudes and practices that may either: (a) conform to their own, and so reinforce their self-identity and behaviour; or (b) contradict them and suggest alternatives that they may adopt, especially if there is considerable pressure to do so.

The search for neighbourhood effects has been especially characteristic of electoral geography, with a number of studies showing greater spatial polarization of, for example, support for a political party in an area than suggested by its residents’ characteristics. Most of those studies use aggregate data, however, and may involve an ecological fallacy. Relatively little is known about the processes that generate the observed patterns, although the importance of interpersonal influence is often assumed, generating what is known as ‘conversion through conversation’. Similar effects are postulated in the spread of other attitudes and behaviour patterns, in education, for example.

Suggested reading

**neighbourhood unit** A relatively self-contained urban residential area. Most units are in planned residential developments, either suburban districts or new towns and similar settlements.

The concept of a neighbourhood unit was first deployed in Chicago in 1916 and formalized by Clarence Perry (1872–1944) in 1929. It suggested the importance of scale in planning residential areas: each neighbourhood unit should be of sufficient size that it was relatively self-contained for certain functions – primary schools and daily shopping, for example – and should develop as an integrated community. British garden cities were planned with neighbourhood units of about 5,000 persons: all unit facilities were within walking distance and motorized transport largely excluded.

Although the general concept continues to underpin some urban planning, the assumption that people wish to constrain parts of their daily/weekly lives to such relatively small bounded territories has generated criticism, while greater reliance on personal transport has broken down the utility of such a cellular division of urban space.

**neo-classical economics** A school of economics defined by the study of rational economic choice and the price-based optimal allocation of resources, using a body of analytically rigorous and mathematically sophisticated theory and techniques. It is the school of economics, at least in Anglo-America, ubiquitous, hegemonic and mainstream. The economist Roy Weintraub says, ‘we are all neoclassicists now’.

Robbins (1932, p. 16) provided the iconic methodological definition of neo-classicism: ‘a science which studies human behaviour as a relationship between ends and scarce means which have alternative uses’. The origins of neo-classicism are earlier, however, with the writings of a troika of late-nineteenth-century European economists: the Englishman William Stanley Jevons (1835–82), the Austrian Carl Menger (1840–1921) and the Frenchman Léon Walras (1834–1910). Alfred Marshall (1842–1924), the first economist at Cambridge, codified, systematized and elaborated their works (including inventing supply and demand diagrams: see figure) in his enormously influential textbook Principles of economics (published in eight editions between 1890 and 1920). After the Second World War, the centre of neo-classical economics crossed the Atlantic to the USA, taking its now familiar abstract, mathematical form. A key influence was MIT’s Paul Samuelson (1915–), the second winner of the Nobel Prize in economics (1970), and author of the canonical text of formal neo-classical theory, Foundations of economic analysis (1947).

Neo-classical economics is neither monolithic nor static, but there are a number of core concerns that continually surface:

(1) The focus on rational economic choice, the belief that individuals have...
both the mental agility and access to information to obtain the most for the least, and applying both to consumers who maximize utility, and producers who maximize profits.

(2) A concern with determining conditions for equilibrium. Rational responses by producers and consumers to market signals produce equilibrium such that there is no incentive for any individual to change their decision: market equilibrium is the solution to the problem of individual maximization.

(3) An emphasis on defining competitive market efficiency such that there is an optimal allocation of resources among competing uses. If not, there is competitive market failure, requiring correction.

(4) An assertion of the methodological sovereignty of independent, rational individuals, and who form the back-stop of neo-classical explanation. Everything – institutions, firms, social classes – is reducible to the law of individual rational choice (METHODOLOGICAL INDIVIDUALISM).

Criticisms of neo-classical economics are endless. They include objections that neo-classicism is nothing but an ideology, a sop for market capitalism; that the rational choice assumption is empirically false, logically inconsistent and morally suspect; that equilibrium, with its assumption that time has stopped, holds at best in Heaven and never on Earth; that society is always more than the sum of its rational agents (there is such a thing as society); and that the use of mathematics is primarily for internal sociological purposes and not for meeting scholarly ends (even Samuelson said that his intensive knowledge of mathematics made him feel like an Olympic-trained athlete with no race to run).

Neo-classical economics entered economic geography as part of the QUANTITATIVE REVOLUTION from the late 1950s, and also at the same time through an allied movement, REGIONAL SCIENCE (King, 1979). The central intellectual problem was to introduce space to a theoretical system that had never systematically included it. While economic geographers and regional scientists made attempts to do so via LOCATION THEORY, there always remained fundamental problems in couching neo-classical competitive equilibrium models within an economy distributed over space (see SPACE-ECONOMY), because the spatial constitution of an economy inherently confers monopolistic advantage. Consequently, the core neo-classical postulate of competitive market efficiency is violated (see (3) above). This is yet another example of what Harvey (1985b, p. 142) identifies as the ‘numbing effect’ of space on the ‘central propositions of any social theory’. In any case, economic geographers were never as mathematically astute as neo-classical economists, nor did most of them share their penchant for ABSTRACTION and rigour. Consequently, the importation of neo-classical theory was frequently half-hearted, incomplete and prone to mistakes. From the late 1990s, there was a second-wave attempt to link economic geography to neo-classicism through the NEW ECONOMIC GEOGRAPHY, but this has been even more unsuccessful as measured by the degree of disciplinary acceptance than in the first go-around.

neo-geography A term – coined by a non-geographer – referring to the bespoke creation of MAPS using the INTERNET, involving the shared use of mapping resources (such as Google Maps and GEOGRAPHICAL INFORMATION SYSTEMS) to which information is added. Those bespoke maps can incorporate a range of other materials to illustrate the characteristics of individual places – such as photographs. It is seen as part of a movement that is de-professionalizing CARTOGRAPHY and making map construction feasible for a wide range of users. Such construction can involve the input of data from devices such as GLOBAL POSITIONING SYSTEMS – allowing, for example, the real-time mapping of journeys and tracking of movements.

Suggested reading
neo-liberalism A doctrine, loosely conceived, that argues for the desirability of a society organized around self-regulating markets, and free, to the extent possible, from social and political intervention (Cypher and Dietz, 1997, pp. 222–32). The term came into prominence in the 1980s, especially in Latin America, where it referred to agendas imposed by leaders such as Chilean dictator Augusto Pinochet—who, with backing from US-trained economists, opened the economy to foreign investors while pushing economic deregulation and privatization of state enterprises—and to the forms of restructuring promoted under Margaret Thatcher in the UK and Ronald Reagan in the USA (Harvey, 2005, pp. 7–9). The US government, along with the International Monetary Fund (IMF), the World Bank and the World Trade Organization (WTO), has aggressively promoted the policies associated with neo-liberalism; and with the collapse of socialist and communist projects since the 1980s, US leaders asserted broad agreement over neo-liberalism under the heading of ‘the Washington Consensus’. Notwithstanding this geographical locus, neo-liberal policies have gained adherents around the world (Toye, 1987).

Neo-liberalism can be analysed in various ways, including as a set of theoretical propositions, as a variety of actual practices and as a manifestation of specific social interests. As a set of theoretical propositions, neo-liberalism is to its advocates an update of basic ideas about economic and social life that the classical liberal theorists of the eighteenth and nineteenth centuries put forward (see liberalism). Neo-liberals cite favourably Adam Smith’s contentions about the capacity of markets to regulate themselves and to produce greater social prosperity than mercantilism (Smith, 1976 [1776]), as well as David Ricardo’s arguments for the greater aggregate prosperity that trade specialization can produce, based upon comparative advantage and minimal tariff barriers (Ricardo, 1992). Theorists such as Friederich von Hayek and Milton Friedman (Friedman, 2002 [1962]; Hayek, 1981) reworked these ideas and used them to argue against a range of Keynesian economic policies—especially social welfare and counter-cyclical government spending policies—that had become prominent in Western countries since the Great Depression of the 1930s. Their arguments, however, did not gain substantial support in governing circles until the 1970s, when some of them came to be advertised as part of the theoretical basis for the policies of the New Right (Harvey, 2005, pp. 19–31).

As policy, many neo-liberal practices differ from the theories (Peck and Tickell, 2002; Harvey, 2005, pp. 70–81). While neo-liberals have argued the virtues of minimalist or ‘night-watchman’ states, the states that have most aggressively promoted neo-liberalism have often been far from non-interventionist. Pinochet’s military dictatorship provided a model that was to be replicated in many other developing countries undergoing IMF-mandated structural adjustment policies, imposing specific forms of economic liberalization through a strong state that engaged in political repression. Similarly, neo-liberal reforms in China have been accomplished under a one-party state that exercises strict control over various aspects of social and economic life. Moreover, actual neo-liberal economic measures have typically been selective and uneven.

Contradictions between theoretical propositions and actual practice lead some commentators to argue that neo-liberalism is best seen not as a fully coherent doctrine, consistently applied, but as a reflection of the class interests of particular capitalists and their allies (Duménil and Lévy, 2004; Harvey, 2005). In this view, the global economic downturn in the 1960s and 1970s led the most internationally mobile groups of investors—especially those involved in international finance—to begin attacking state policies that were seen as hindering capital mobility and reducing profit rates. Through both reinvesting capital abroad and advertising the allegedly undesirable effects of regulations on capital mobility, these investors attempted to restore profitability by driving down wages and production costs in core areas of the global economy, selectively making use of lower wages, production costs and emerging markets in countries of the global south.

These efforts to restore profitability through neo-liberal globalization have been partially successful, but they have also generated various forms of backlash. First, the attacks on state programmes that enhance social welfare have generated responses from popular forces that see neo-liberalism as antithetical to improved life chances for the least privileged members of society (Harvey, 2003b, pp. 137–82; Harvey, 2005, pp. 198–206). Second, neo-liberalism has come under increasing attack from within the ranks of the elite after Washington Consensus policies were seen to have been inappropriately applied during the Asian economic crisis of 1997–8.
When outputs exceed inputs, a "surplus" exists that forms the basis of the social conditions of income distribution. Sraffa subtitled his book *Prelude to a critique of economic theory*. Although he did not engage in the critique himself, his model has provided the basis for subsequent criticisms of both neo-classical economics and Marxist economics. These were first taken up in the 'capital controversy', where the neo-classical theory of profit (profit is the marginal product of capital) was shown to be logically untenable, and later in the 'value controversy', where the Marxist Labour Theory of Value was shown to be redundant in calculating prices. A number of economic geographers have elaborated Sraffa's work since Scott's (1976b) pioneering paper linking Sraffa's model of production with von Thünen's theory of agricultural rent. But the formal, minimalist style of Neo-Ricardianism is out of synch with the more expansive, empirically grounded, and less formal economic geography of today, and connections have been few, and even more rarely taken further.

**network society** A term coined by Manuel Castells (1996b, 1997, 1998) in an influential trilogy of books to describe globalizing societies dominated by accelerated economic, cultural and social flows, mediated predominantly by information technologies (see also globalization). The trilogy explored the growth of networked enterprises, global processes of social exclusion and the changing nature of time and space, identity and state formation. Its key argument was that network societies are dominated by a separation of the space of flows – the globalized and accelerated domains that are orchestrated through new information and communications technologies – from the space of places – geographically confined sources of individual and collective identity.

Castells (1996b).

**network(s)** A particular kind of spatial arrangement that consists of a collection of linked elements which typically exhibit a decentralized and non-hierarchical form. With the word ever more ubiquitous in popular, business and academic usage, it is increasingly important to recognize that the proliferation of the basic topological metaphor of the network can conceal a range of very different analytical commitments, both explicit and implicit. At least the following approaches may be usefully distinguished, each with...
their different main constituents/actors, types of relation foregrounded and methods of analysis:

1. Infrastructural technically based networks, such as electrical, road, rail, sewerage and telecommunications systems, can be described according to their density, connectedness and orientation (Haggett, 1969: see INFRASTRUCTURE).

2. Social networks, such as kinship, friendship and communities, have historically been analysed both quantitatively by social network analysis and more qualitatively using tools derived from social anthropology (Strathern, 1996).

3. Network-based models of organization have tended to merge the distinctive features of the previous two approaches, as the nature of collectives from the informal and local to formal and global are increasingly seen as exhibiting this kind of form (Castells, 1996b; Barry, 2001).

4. Finally, actor-networks (Latour, 1993) are the distributed forms of agency that emerge from articulation of humans and non-humans as seen by practitioners of the conceptual approach that originated in science and technology studies (STS) and is known as ACTOR-NETWORK THEORY.

neural networks Methods of finding solutions to a range of technical problems using computer ALGORITHMS based on models of the human brain. The networks are ‘trained’ to find solutions to new problems by being given exemplars on which to base their decisions, such as which category to assign an individual observation to when the category boundaries are fuzzy (cf. FUZZY SETS). The approach is particularly valuable in various forms of pattern recognition and classification and is widely used in REMOTE SENSING studies for classifying segments of the Earth’s surface according to their LAND COVER (Foody, 1996). The spectral signatures of different land-cover types vary, and many small areas for which data are obtained contain a mixture of types. The goal is to allocate each observation unit (PIXEL) to a relatively homogeneous category. ‘Training’ sites are defined, using synthetic pixels with homogeneous land cover, and the neural network algorithm, through an iterative procedure, allocates all of the observed pixels to the type it most closely resembles. It is then possible to estimate the proportion of the land surface under different types of cover.

A similar approach has been suggested for CLASSIFICATION of socio-economic data. Very few small areas – such as CENSUS TRACTS – are homogeneous in their population characteristics so clear boundaries between types of area cannot be defined a priori on other than pragmatic grounds (e.g. use of quartiles); they are the same as pixels with mixed land uses. Using neural network approaches, IDEAL TYPES are defined (with different levels of homogeneity and mixtures, for example) and the individual tracts are allocated to those they most resemble (Mitchell, Martin and Foody, 1998).

NEW ECONOMIC GEOGRAPHY

New Economic Geography An approach associated primarily with a group of American neo-classical economists (see NEO-CLASSICAL ECONOMICS) who from the early 1990s sought to apply theoretical rigour, analytical methods and econometric (statistical) techniques to a SPACE-ECONOMY. Such interest was surprising, given economists’ historical attachment to an a-spatial ECONOMY, to ‘a wonderland of no dimensions’ (Isard, 1956, p. 25). For Paul Krugman (1993a, p. 33), however, the economist most central to the movement, the New Economic Geography was ‘a vision on the road to Damascus’: ‘I suddenly realised that I had spent my whole professional life . . . thinking and writing about economic geography, without being aware of it’ (Krugman, 1991, p. 1).

Krugman’s epiphany was that the analytical framework he previously deployed to understand international TRADE was perfect for comprehending economic geography: ‘Economic geography, like . . . trade theory, is largely about increasing returns and multiple equilibria. The technical tricks needed to make models tractable are often the same’ (Krugman, 1995b, p. 41). That term ‘MODEL’ is critical. While conventional economic geography was ‘a field full of empirical insights, good stories and obvious practical importance’, it was ‘neglected’ – that is, neglected by economists – because nobody had seen a good way to formalize it’ (Krugman, 1995b, p. 41). Krugman’s project was to take works of economic geographers and to make them (as he saw it) intellectually viable by expressing them in the formal vocabulary of economic models. As he writes, ‘we will integrate spatial issues into economics through clever models . . . that make sense of the insights of the geographers in a way that meets the formal
NEW INTERNATIONAL DIVISION OF LABOUR (NIDL)

standards of the economists’ (Krugman, 1995b, p. 88). In his manifesto, Krugman (2000, p. 51) identifies ‘a slogan’ for his project: ‘Dixit–Stiglitz, icebergs, evolution, and the computer.’ Dixit–Stiglitz is the ‘clever model’; icebergs refers to the ‘technical trick’ for introducing transport costs (and hence geography), evolution points to the dynamic character of the models (as opposed to the static kind characterizing traditional location theory), and the computer simulates solutions for multiple equilibria (Krugman says that his laptop ‘lets me produce a paper – equations, simulations and all – in a hotel room over a weekend . . . ’) (Krugman, 1995a, p. 37).

There was a precedent for the New Economic Geography in regional science, which was established in the 1950s to apply rigour, scientific analysis and statistical methods to a space economy. Unsurprisingly, given the attempt to occupy the same terrain, the two movements have an uncomfortable relation. Krugman implies that regional scientists have yet to find ‘clever models’, while regional scientists dismiss Krugman’s work by claiming that ‘it’s obvious, it’s wrong, and anyway [it was] said years ago’ (Isserman, 1996). The relationship between the New Economic Geography and economic geography as practised in human geography is also uneasy. There was an initial flush of interest represented by the publication of a joint reader, The Oxford handbook of economic geography (Clark, Gertler and Feldman, 2000), and a new journal, the Journal of Economic Geography, which started publishing in January 2005. Both organs promoted cross-disciplinary exchange. At least as measured by citation impact scores, the new journal attracted large numbers of readers from both economic geography and economics. But being between the same covers does not prove intercourse, and Martin’s (1999b, p. 70) verdict on the New Economic Geography, that it produces a ‘dull sense of déjà vu’, is still likely to be shared by many economic geographers. The more than 100-year history of economic geography is littered with failed attempts to engage economists. This is turning out to be another one.

New International Division of Labour (NIDL) A recasting of the international division of labour associated with the internationalization of capital and the growth of newly industrializing countries and regions. In one sense, the term is unhelpful, for the uneven development of capitalism ensures that the global division of labour is constantly changing. As Marx and Engels (2002 [1848]) put it in The communist manifesto, ‘All that is solid melts into air.’ In another sense, however, the phrase has some merit. Particularly in the heyday of the Bretton Woods system (1944–73), neither capital nor labour moved extensively across the global stage. National economies were placed squarely at the heart of an international trading system. This was partly in response to a reading of the Depression years and the Second World War. The Bretton Woods system was meant to protect national space economies in the ‘First World’ against undue economic and political turbulence (Corbridge, 1994). When the Bretton Woods system came undone, it gave way to high unemployment and inflation. According to Fröbel, Heinrichs and Kreye (1980), many capitalist firms in the West now had to face the consequences of the postwar corporatist settlement – a settlement that had increased returns to labour, including labour employed by the state, relative to those returned to capital. Firms could evaporate, innovate or emigrate. With the emigration of capital, they reasoned, came a change in the international division of labour that was distinctive – new – when viewed against the period from 1950 to 1975.

There is no doubt that the rise of newly industrialized countries such as Taiwan and South Korea came as a shock in the 1970s (see Asian miracles/tigers). Some versions of dependency theory maintained that the development of the core depended upon the continued non-industrialization of the periphery. Gunder Frank argued that Taiwan and South Korea were exceptions to a rule that still held. They had simply been allowed to develop by the USA for geopolitical reasons. Less blinkered theories accepted that geopolitics was part of the story, but they also noted the way in which the state in both countries had achieved a degree of relative autonomy from domestic proprietary classes. They had used this power to effect land reforms and proactive industrial policies. In the case of South Korea, industrial policy was fastened mainly around large-scale domestic capitals, including leading banks and chaebol such as Samsung. In Taiwan, industrial development was sponsored by networks of small-scale firms (Kohli, 2004). What NIDL theorists have added to this mix – and their work has
been continued by globalization theorists – is close attention to the ways in which these new industrial spaces (including high-tech spaces in Indian cities such as Bangalore and Hyderabad) are linked to international capital and consumer markets by firms such as IBM, Hewlett-Packard and Sony. NIDL theorists largely discounted the domestic bases of industrial success in the Asian Tiger economies and important policy differences between them. They were ahead of the game, however, in recognizing some of the global shifts set in motion by the restructuring of capitalism as it moved into an era of neo-liberalism and deepening time-space compression.

**new town** A planned town in an area that previously lacked a substantial urban settlement. Although such planned settlements can be found throughout history, the term was first widely used after passage of the British New Towns Act 1946. The New Town movement there, based on the earlier Garden City movement and the concept of neighbourhood units, stimulated the creation of a number of new settlements, most of them outside London, designed to limit urban sprawl and protect agricultural land (see green belt), to decentralize population and economic activity and to contribute to rehousing policies necessitated by both slum clearance in inner cities and the destruction of much housing during the Second World War. The first of those towns was Stevenage, with ten being created between 1946 and 1950. Eventually, 28 were designated and built, including major cities such as Milton Keynes, which incorporated several small existing towns.

The model set in the UK has been widely adopted over the past 60 years, and there are New Towns in a large number of countries. Although the utopian ideals of many of the movement’s originators have not been met – notably with regard to the creation of relatively self-contained communities – most new towns represent relatively high standards of housing and urban design.

**NGO** The acronym for Non-Governmental Organizations – not-for-profit voluntary associations that seek to act for the public good. The term covers a variety of bodies from international agencies with large professional staffs to small groups of unpaid volunteers. Their functions are diverse and include campaigning, humanitarian relief, development work, social welfare, cultural activities and conservation. Many provide services and programmes on behalf of governments and intergovernmental organizations and some have become highly dependent on government financial support. According to some accounts they operate in the space between the state and the private sector and are sometimes misleadingly regarded as synonymous with civil society.

Suggested reading

**NIMBY** The acronym for ‘Not-In-My-Back-Yard’, an attitude adopted by individuals resisting the siting of a source of perceived negative externalities (such as shelters for the homeless (see homelessness) and those recently released from prison) close to their homes, and campaigning for it to be located elsewhere (cf. zone of dependence).

**nodal region** A region whose defining characteristic is the links between its component parts and one or more focal points. Nodal (or functional) regions are usually defined using flow data, as in the definition of hinterlands: they form the core of Haggett’s (1965) locational analysis schema.

**nomadism** A livelihood – including hunter-gathering, pastoralism, begging and commerce – that involves the intra-annual movements of families (or other social production units), necessitating the displacement of their dwelling(s). During the nineteenth and early twentieth centuries, the term was used more indiscriminately to refer to any livelihood associated with intra-annual human mobility. Nomadism has historically elicited both fascination and revulsion (negative connotations of the terms shiftless, rootless, vagabond, vagrant, itinerant etc.) within Western culture and science (see also migrancy). Cultural evolutionists have seen it as a primitive cultural trait, while environmental determinists and cultural ecologists have portrayed it as a feature inhibiting the development of complex, hierarchical political systems (see cultural ecology; environmental determinism). Reflecting this history, nomadism incorrectly conjures up essentialist notions of wandering and livelihood.
stasis. However, studies of nomadic societies find that their mobility is neither socially nor ecologically aimless, but rather shaped by the physical availability of resources and by the social networks required for security and maintaining access to these resources. Moreover, the degree of mobility (rate and distance of displacements) varies significantly among nomadic households, reflecting the different opportunities and constraints that they face.

nomadology Although they do not provide an explicit definition of the term, Gilles Deleuze and Félix Guattari (1987) present the discipline of nomadology as the opposite of history, which they associate with a sedentary, state-centric point of view. For Deleuze and Guattari, the point of nomadology is not a historical study of nomadic peoples but, rather, a study of different spatial practices. Unlike the state, the nomadic (or rhizomatic, see rhizome) ‘war machine’ is understood to occupy space without ordering, counting or surveying it. Nomadology is thus the study of what these philosophers call ‘smooth space’, a space of creativity, emergent properties and intensive becomings.

nomos The matrix of laws, norms and conventions that orders conduct within a society. The nomos is: (a) socially constructed, and so varies over space and time; and (b) generally accepted, and so serves as a template for political–moral ordering. The term emerged with the rise of democracy in fifth-century Athens, where the political structure of the classical city-state implied that the nomos is also (c) spatially articulated (in the sense of a distribution or assignment of powers). The term entered geopolitics through the German jurist Carl Schmitt (1888–1985), who invoked the concept to argue that in Europe in the sixteenth and seventeenth centuries the theological–moral model of the just war yielded to the secular–juridical model (i.e. the nomos) of a regulated war between sovereign states that claimed a monopoly of the legitimate means of violence. Unrestrained violence was then projected ‘beyond the line’ into the non-European world: ‘Europe sublimate[d] its animality by establishing the

Americas as an extralegal zone in which bestial deeds [could] be “acted out” far away’ (Rasch, 2003). Schmitt identified this zone with ‘the state of nature in which everything is possible’ and with the space of exception (see exception, space of). He argued that by the early twentieth century the line had dissolved, and the wild zones of colonial violence had appeared within the ruins of the European order (Schmitt, 2003 [1950]). Schmitt’s writings have attracted renewed critical attention today, through the bearing of his political theology on the Bush administration’s war on terror (see terrorism), and through the radicalization of his work in the political philosophy of Giorgio Agamben (see Minca, 2006). In both cases, considerable interest has attached to Schmitt as ‘above all, a spatial thinker’, where the concept of nomos is central (Dean, 2006, p. 7).

nomothetic Concerned with the universal and the general. The term derived from the German philosopher Wilhelm Windelband, who, in 1894, used it to identify one of two possible goals of concept formation:

The theoretical interests associated with nomothetic concept formation highlight those common qualities of objects of experience that lead to the formulation of general laws of nature. The process is one of continual abstraction in which the special qualities of an object are filtered out and the object is seen as a general type that exists with certain relations to other, general types. (Entrikin, 1991)

Windelband contrasted this with idiographic concept-formation, which is concerned to achieve a complete understanding of the individual case (see kantianism; cf. ideal type).

Windelband’s views were considerably more nuanced than the caricatured oppositions between idiographic and nomothetic that were propelled into geography after the middle of the twentieth century. These versions ignored Windelband’s insistence that both approaches were directed towards the formation of analytical concepts. Instead, in the wake of the Hartshorne–Schaefer exchange over exceptionalism, the proponents of spatial science ridiculed regional geography in particular for its focus on the unique – its supposedly inherent inability to provide conceptual rigour or intellectual substance – and claimed that geography should focus on generalization and work towards the formulation of scientific theories and laws of spatial
organization. But these caricatures have largely disappeared, not least through the critique of classical spatial science, the emergence of post-positivist geographies and the reformulation of regional geography. As Phillips (2004, p. 40) concluded, ‘the debates over idiographic/regional interpretive geography versus nomothetic/quantitative/scientific geography have come and (mostly) gone; contemporary critiques emphasizing contextuality and contingency are with us now’. DG

non-place A term coined by French anthropologist Marc Augé to describe certain qualities of airports, highways, theme parks, motels, department stores and shopping centres, tourist sites and so on. These sites have in common gatherings of individuals and groups of people who temporarily come together at the same site, but who have no particular bond to each other. Rather than a social bond determining the nature of these collective gatherings, it is typically signs and texts that guide people’s movements within these spaces or that direct them to other spaces. In that latter capacity, the non-place is a conduit, a potential that structures the gaze to some other site. Some interpreters take non-place to be a negation of place (cf. placelessness) but in Augé’s terms ‘place’ works dialectically with ‘non-place’: ‘the first is never completely erased, the second never totally completed; they are like palimpsests on which the scrambled game of identity and relations is ceaselessly rewritten’ (Augé, 1995, pp. 78–9). But for some critics, Augé has not been clear about the dialectics of place and non-place, and one gets the impression that a timeless passenger/commuter subject is the sole inhabitant of the non-place. Against this view is one that recognizes that those who, for example, work in these spaces have a much richer and more complicated relation to them and to one another, so that it becomes necessary to think of multiple ‘placings’ (of diverse people, plans, histories, blueprints) as the substantive content of ‘non-places’ (Merriman, 2004).

non-representational theory A style of engagement with the world that aims to attend to and intervene in the taking-place of practices. Non-representational theory – a term first coined in human geography by Thrift (1996) – emerged from a caution and a concern about the overvaluation of the ‘representational–referential’ dimensions of life following the discipline’s cultural turn. It responds to two questions:

1. How to disclose and attend to life as a differential, expressive process of becoming, where much happens before and after conscious reflective thought?
2. How to foster types of description or presentation that attempt to co-produce new events by engaging with and intervening in the practices that compose life?

Non-representational theory is not a new paradigm that would eliminate or supersede others, nor does it offer a set of rules and conventions that could form one of a number of holistic conceptions of the world; rather, it names a differentiated set of ways of learning to address these two questions. Non-representational theory is consequently composed of a multiplicity of perspectives and takes its inspiration from a range of sources, including Heideggerian theories of practice, post-phenomenology, various micro-sociologies, actor-network theory, Deleuze and Guattari’s heterodox version of post-structuralism and corporeal feminism (see figure). The plural – ‘non-representational theories’ – perhaps conveys a better sense of the complicated genealogy of these theories and the constantly shifting, contestable foundations of non-representational theory in human geography (compare Thrift (2008) with Thrift (1996)).

Whilst non-representational theory is, irredeemably plural, it is held together by two broad starting points – one an imperative, the other a promise – and both of which have been subject to criticisms.

First, non-representational theory affirms an imperative to expand the foci of (‘new’) cultural geography beyond either a focus on a sphere of representation or a human subject who relates to the world by representing aspects of the world through an act of interpretation (by, for example, undertaking active ‘readings’ of dominant or residual meanings). Each mirrors the other in that they both assume that the primary relation between an (individual or collective) subject and the world is at the level of signification. In contrast, non-representational theories are theories of practice in that their focus is on what humans and/or non-humans do, and how the reproduction and revision of practices underpin the genesis and maintenance of interpretation and thus meaning. Whilst this move resonates with the attention to practical logics of the body in some humanistic geographies...
and borrows from various forms of micro-sociology, a critical difference is that practices tend to be conceptualized as processually emergent compositions of human and non-human materialities (Whatmore, 2002a). From within this context, practices are understood as always embodied and composed of a set of modalities – including affect and emotion (see emotional geography) – that do not have to cross over a threshold of signification to achieve political effects (see Harrison, 2000). One forceful response to this has been to claim that non-representational theory cleaves the non-representational from the representational and installs a dualism between the two by attending to the former and ignoring the varied effects of the latter. But Dewsbury, Harrison, Rose and Wylie (2002) take care to stress that non-representational theories are not anti-representation (cf. Jones, 2008) but, rather, conceptualize representations as ‘presentations’. That is, representations are not understood as masks or veils that express some a priori system of transcendent categorizations, but are instead encountered as constitutive elements within practices (although this has raised questions about how to develop conceptual vocabularies for describing the a-signifying effects of different forms of ‘presentations’ that do not reproduce a naive psychologism or a cause/effect model). Non-representational theory, then, enacts a break with the version of culture as structuralizing/signifying that defined the ‘new’ cultural geography. Such a move is seen as a necessary response to a contemporary political moment in which various non-representational modalities – including affect – are caught up in the emergence of new forms of sovereign power and biopower (Thrift, 2008; but see Barnett, 2008).

Second, non-representational theory expresses the promise of encountering a now expanded social as a practical achievement – an ordering rather than an order – emergent from multiple spatially and temporally distanced relations. The result has been an attention to how more or less durable, differentially extensive, orderings are composed from relations between human and non-human actors – or perhaps more properly actants (see actor-network theory). Society then becomes a set of partially connected networks or assemblages in which embodied, expressive practices act as the ongoing basis for coherence and change (Rose, 2002b). Recent work has moved to address early criticisms that such a focus on the non-representational reproduces or even celebrates a figure of the undifferentiated human (Nash, 2000) by exploring how
social differences such as race or sexuality are enacted through and disrupted by the workings of a range of non-representational modalities (e.g. Lim, 2007). However, heavily influenced by Deleuze and Guattari (McCormack, 2005) and work on performativity (Dewsbury, 2000), the prefix ‘non-’ in ‘non-representational theory’ names an attunement to moments of indeterminacy and undecidability, in which new events emerge to exceed and potentially disrupt given orderings (although see Anderson (2004) and Harrison (2007a) on boredom and suffering for criticisms internal to non-representational theory around how an attention to newness can downplay relations which are, respectively, suspended and broken).

To work through the imperative and promise of non-representational theories, there has been a nascent experimentation with research methods, as well as diagrammatic and narrative forms of presentation, that take as their task to learn to witness the ongoing taking-place of life as a composite of embodied practices. Theory is called here to act as a ‘modest supplement’ to life that would enable new forms of description – a move that has occasionally sat uncomfortably with the intense theoretical experimentation that has also been a mark of non-representational theory. Substantive work has begun, however, to draw this set of theories into often disruptive encounters with a range of sub-disciplines – see, for example, Wylie (2005) on landscape or Horton and Kraftl (2006) on children’s geographies. Taking the two commonalities together, non-representational theory can be understood as a style of engagement with the world that, encountering a range of non-representational theories that exceed human geography, begins from the non-representational dimensions of practice and performance.

normative theory A theory or theoretical claim that is prescriptive, saying what ought to be. The theory of neo-classical economics says that markets should be competitive; the theory of marxism says that expropriators should be expropriated. Whenever the word ‘should’ appears, a normative theoretical claim is lodged. The contrast is positive theory, which is a claim about what is. Competitive markets exist in China. Donald Trump is an expropriator. Positive claims (such as these) might be wrong but, if so, they can be scientifically falsified by facts. Normative theory is never falsifiable, and for that reason often engenders sharp disagreement.

The use of the distinction is most associated with economics. The early Cambridge economist John Neville Keynes (1852–1949) in his The scope and method of political economy (1930 [1891], pp. 34–5) distinguished between positive economics, which is ‘a body of systematized knowledge concerning what is’, and normative economics, ‘relating to criteria of what ought to be and concerned therefore with the ideal as distinguished from the actual’. Keynes made the distinction so that economists could be scrupulously clear about their role and status: when speaking of what is (positive economics), they were scientists, and when speaking of what ought to be (normative economics), they were policy advisors. The two should never be confused.

In human geography the distinction between the positive and the normative was found most often in economic geography – not surprisingly, given its origins – and connected with the period of the quantitative revolution, when economic geographers most demanded criteria delineating scientific work (positive theory). Ironically, however, much of the location theory seized upon and elaborated during that period was normative rather than positive, and so did not constitute science in Keynes’ terms. Location theory was underpinned by a set of ‘ideal’ assumptions such as an isotropic plain, transportation costs proportional to distance, equal population density and perfect rationality. August Lösch, one of the principal architects of location theory, was perfectly clear about its normative character: ‘the real duty of the economist is not to explain our sorry reality, but to improve it. The question of the best location is far more dignified than determination of the actual one’ (Lösch, 1954, p. 4[1940]). But this motivation was rarely registered by economic geographers at the time.

In any case, the discussion became moot as the very distinction between positive and normative theory began to unravel from the early 1970s. Olsson (1980), a former acolyte of positive theory, argued that a mainstay of economic geography’s scientific approach, the family of spatial interaction models, was irredeemably compromised by value judgements – ‘is’ disguised as ‘ought’. Similarly,
Harvey (1973, 1974a) found hidden normative claims lurking in every corner of positive theory: in economic theories of the city, in theories of population and resources, in quantitative techniques. All THEORY is normative theory. Our VALUES go all the way down, and we can no more escape them than avoid the smell of the air we breathe (see also ETHICS).

North–South  The phrase gained in popularity in the 1970s as a way to describe richer, industrial countries on the one hand (the North) and poorer, mainly non-industrial countries on the other (the South). The phrase had the advantage of moving beyond the First, Second and Third Worlds. Although the South clearly referred to mainly ex-colonial or developing countries in LATIN AMERICA, AFRICA and ASIA, it seemed a more neutral term than the THIRD WORLD. It also spoke to the fact that Southern countries were reorganizing themselves politically in the 1970s. In the 1950s, the Third World referred to a group of non-aligned countries determined to forge a new way in the global political economy. In the 1960s, the meaning of the Third World was changed to define a group of countries that were marked by what was then called UNDERDEVELOPMENT. The idea that these countries might have significant geopolitical or geo-economic power was not taken seriously. This changed, however, when the Organization of Petroleum Exporting Countries (OPEC) drove up oil prices fourfold in 1973–4. The success of this action encouraged a broader group of developing countries, the Group of 77 – formed in 1964 at the first UN Conference on TRADE and DEVELOPMENT – to press for a New International Economic Order. It was partly through the Group of 77’s demands for fairer and more stable trading arrangements, more AID, special financial facilities and greater voting rights in the UN that a notion of the South was born.

In the 1980s, the Americans and other Northern powers roundly defeated their demands for a New International Economic Order. However, a group of well-meaning social democrats in the North did speak back to the South’s demands through the first and second reports of the Brandt Commission: North–South (1980) and Common crisis (1983). Although Brandt Commissioners tried to direct attention to the widening (and in their view dangerous) gaps between Northern and Southern countries, not much happened. Indeed, it can plausibly be argued that the end of the COLD WAR weakened Southern countries, particularly in sub-Saharan Africa (Dodds, 1999; Fawcett and Sayigh, 2005). These countries were no longer important to either the USA or the former Soviet Union. The irony, then, or the tragedy, is this: in the 1970s, a map of the world that sought to depict the global North was clumsy in the extreme. It stretched to include mainly temperate regions both sides of the Equator, pulling together North America with Australia and New Zealand. Most of the world’s land mass, in any case, is north of the Equator. The South mainly occupied a more discrete space in the sub-tropical and tropical worlds. By the end of the century the conceptual integrity of the North seemed to make more sense, bolstered in part by GLOBALIZATION. The South, for its part, has found it increasingly difficult to advance a coherent political position. The Group of 77 now has 133 members, but is largely impotent in the face of the North’s veto on key economic and political changes.

Nuptuality  The extent of marriage (or marriage rate) within a population. As research in DEMOGRAPHY associated being married with elevated fertility, delaying the age of marriage is argued to reduce fertility, such as occurred in some European countries in the early expanding phase of the DEMOGRAPHIC TRANSITION. However, sensitivity to the growing diversity of partnering and parenting arrangements in contemporary society complicate this thesis, and have contributed to considerable interest in family and HOUSEHOLD organization (e.g. Duncan and Smith, 2002; Wright, Houston, Ellis, Holloway and Hudson, 2003).

objectivity  The term ‘objectivity’ has at least three distinct meanings in geography. The first is a relatively common everyday one, where objectivity is associated with impartiality or disinterestedness. Here, one or another approach is said not to have a particular axe to grind, or any pre-set principles or ideological positions to defend. This commonsense understanding of objectivity has a parallel in some of the humanities and professions, where objectivity derives from professionals following well-established codes to guide the careful marshalling of evidence, cross-checking of sources and accurate and unbiased presentation of information. Objectivity, in this sense, is thought to derive from careful gathering of information, mastery of the evidence and ‘balance’ in presenting an argument.

In a more profound sense, objectivity as an element of scientific method refers to claims about the characteristics of an object that are said to exist independent of our perception of it. In this view, objectivity presupposes some form of unmediated or direct observation—what Haraway (1985) called the ‘god-trick’—and became the basis for the claims by objectivist science that it was merely mirroring nature in a form that was unmediated and ‘value-free’ (see cartesiansm).

Since the 1970s, many human geographers have reacted against the objectivist conception of objectivity. Drawing from hermeneutics, they acknowledged pre-judgements (‘prejudices’) as indispensable to a developing, dialogical process of understanding. Drawing on feminism and marxism, they argued that all claims to objectivity are ideological, denying their histories, commitments and embeddedness in particular social institutions (see ideology). As Habermas (1987a [1968]) proposed, knowledge and human interests are always necessarily connected. Critical human geography insisted on the need for an ideology critique to unmask the actors, interests and consequences of such claims to objectivity (Gregory, 1978a). A transcendental or universal ‘god’s eye’ view of objectivity was displaced as critical human geographers turned to analyses of the role of social interests, human agency and institutions in shaping existing and possible worlds (Harvey, 1974b). Thus, a third meaning of objectivity sees knowledge (including scientific knowledge) as always historically and socially constructed out of specific projects in particular times and places: knowledge is always produced by someone; knowledge and human interests are always inextricably linked; and the production of knowledge is a social practice like any other with its own commitments, forms of embeddedness and geographies (see situated knowledge). The turn to critical human geographies of this kind marked a rejection of grand narratives, and initiated a period of rich methodological experimentation and the writing of more fallible and open geographies (Natter, Schatzki and Jones, 1996, p. 1). JPi

Occidentalism  The systematic construction of ‘the west’ (‘the Occident’) as a bounded and unified entity. Occidentalism is often treated as the inverse of orientalism: just as Western cultures systematically construct(ed) stereotypes of ‘the orient’, so non-Western cultures produce(d) their own stereotypes of ‘the Occident’ (Carrier, 1995). Hence Occidentalism has been described as an inversion of the Western imaginary, ‘the world turned upside down’, or as a counter-discourse to orientalism (Xiao-me Chen, 1995). Bonnett (2005) has provided one of the most sophisticated and sensitive readings of Occidentalism in these terms. Writing against those who regard the idea of asia as yet another exterior, European construction, he reads two authors, one Japanese and the other Indian, to show how they used their independent constructions of the west to explore non-Western forms of modernity.

In contrast to all these versions, however, Edward Said, one of the main architects of the critique of Orientalism as a system of power-knowledge, insisted that ‘no one is likely to imagine a field symmetrical to [orientalism] called Occidentalism’ because the imaginative geographies produced by non-Western cultures were not bound into a system of power-knowledge comparable to the tensile strength and span of modern colonialism and imperialism (Said, 1978, p. 50). For Said, the distinctive quality of Orientalism was its structural involvement in globalizing
projects of domination and dispossession. For this reason, Coronil (1996) prefers to treat Occidentalism as the condition of possibility of Orientalism itself: the conceptions of the West that underwrite - that make possible - its own representations of non-western cultures. This tactic reminds us that Orientalism not only constructs 'the Orient' but also simultaneously constructs and privileges the West-as-Subject (see eurocentrism).

Occidentalism in a more populist sense gained new impetus in the aftermath of the terrorist attacks on New York City and Washington on 11 September 2001. A common response was to ask 'Why do they hate us?' and to look for answers among 'them' rather than 'us' and, in particular, 'their' supposed hostility to the political and cultural formations of a universal modernity. So, for example, Buruma and Margalit (2004) provided a thumbnail sketch of Occidentalism as 'the West in the eyes of its enemies' and sought to locate today's suicide bombers and holy warriors' within a larger history of 'hatred' and 'loathing' of the West and all works. Theirs was a remarkably shallow reading, which revealed more about the authors than their object of enquiry, and in this sense was another mapping of the Occidentalism that Coronil had so presciently in mind.

Bonnett (2005); Coronil (1966).

**Occupation, military** The assumption of effective control through military action by a sovereign power over a territory to which it has no legal title. Military occupation is thus distinct from military rule, though both may rely on the suspension of the pre-existing rule of law, the imposition of martial law (cf. exception, space of) and the violent domination of the civilian population (see, e.g., Hudson-Rodd and Hunt, 2005). Occupations have taken place throughout human history, most obviously in the expansion of empires through conquest and annexation, and these often involved transfers of population: slaves to Rome, Roman settlers to the colonies. But since the Second World War modern occupations have been governed by international law that both proscribes the acquisition of territory by force (so that occupations are supposed to be temporary affairs) and specifically forbids population transfers. The same body of law requires the occupying power to restore and maintain public order, to respect private property, and to safeguard the health and welfare of the occupied population. In practice, however, as Benvenisti's (2004) review of twentieth-century occupations reveals, these obligations have been more honoured in the breach: most either denied their status as Occupying Powers (even though international law makes it clear that occupation is a matter of fact, not intention or proclamation) or assumed wide discretionary powers.

Military occupations raise at least three sets of crucial geographical questions:

- **Strategy.** What are the objectives of military occupation? Some are the result of military success in war: they may be directed towards permanent annexation and the creation of tributary states for geopolitical and geo-economic reasons (e.g. the Nazi occupation of continental Europe between 1939 and 1945, or the Soviet occupation of much of Central and Eastern Europe between 1945 and 1989); or they may be temporary (but nonetheless protracted) affairs directed towards the replacement of one political system by another (e.g. the US occupation of Japan, 1945–52: see also geopolitics). Many contemporary occupations are the result of international interventions to end regional or civil war ('peace-keeping'; e.g. the NATO occupations of Kosovo and Bosnia from 1995 to the present), though some have entailed the use of military violence on a scale that recalls Tacitus' description of the Roman occupation of Britain: 'They create a devastation and call it peace.' Still others are attempts to create buffer zones to guarantee security (e.g. the Israeli occupation of southern Lebanon, 1982–2000: and see Schofield, 1993). But many occupations have a mix of motives - occupation is rarely a coherent or transparent project - and while modern occupations often cloak themselves in the rhetoric of 'liberation', they often have long-term, transformative ends in view (Bhuta, 2005) and the presence of foreign troops often meets fierce resistance from the occupied population.

- **Logistics.** What power-geometries are necessary to maintain control over an occupied population (e.g. Weizman, 2004)? Military occupations depend on the spatial circulation of information (intelligence about the occupied population and its activities, military orders and public announcements), on supply networks to provide essential resources for occupiers.
and occupied, and on the capacity to mobilize troops to enforce public order. In most cases, CITIES function as the pivots for all three, but during the US occupation of Afghanistan, for example, it was (and remains) far from clear how far the authority of the USA and its proxies extended into the countryside. The crucial importance of cities also makes them centres of rebellion and resistance to military occupation (Gregory, 2007).

- Contact zones. Many of the relations imposed by occupying armies are intrinsically violent – including sexual violence, arrest and imprisonment, forced labour and even GENOCIDE – but the occupied also view interactions across the contact zone in complex ways: Why are some constructed as collaboration, others as doing business to survive and yet others as resistance? During the US occupation of Iraq from 2003 onwards, resistance increased to the point at which it became increasingly difficult to distinguish occupation from the continuation of war (Gregory, 2004b).

It is not necessary to maintain a massive and permanent military presence to continue an occupation: Israel’s continued control over Gaza and the West Bank rests on its capacity to mobilize military force at will (‘incursions’) and on the continuing development of colonies (‘settlements’) as the eyes of what Segal and Weizman (2003) call ‘a civilian occupation’. OCEANS Even though the decline of sea travel and diminishing dependence on self-supplied FOOD sources has removed the maritime world from the realm of landlubbers’ everyday experience, the sea remains a crucial domain for the essential wherewithal that sustains humanity. Three perspectives have dominated most studies of human–marine interactions: the ocean as a RESOURCE provider, the ocean as transport surface, and the ocean as a surface for moving troops and projecting military power. Embedded in each of these analytical perspectives is a certain conception of ocean-SPACE and ocean GOVERNANCE.

The value of the oceans to mankind has political, social, economic, ecological and cultural dimensions. Marine industries include fisheries, mining, non-conventional ENERGY industries, fresh WATER production, coastal services, environmental services, TRADE, TOURISM, sub-marine telecommunications and fibre-optic cable, safety and salvage, naval defence and ocean-related education, training and research. The economic importance of the oceans is immense. According to the Independent World Commission on the Oceans, ‘one recent study suggests that the sum total of marine industries for which data are available, amounts to approximately US$ 1 trillion out of a total global GDP of US$ 23 trillion’ (IWCO, 1998, p. 102).

Ecological services provided by various marine and coastal ECOSYSTEMS of the Earth include the regulation of gaseous exchange with the atmosphere (e.g. the balance between carbon dioxide and oxygen, maintenance of ozone for ultraviolet radiation protection), climate regulation, disturbance regulation (e.g. storm protection, flood control), water supply, cycling of nutrients, waste treatment, food production and raw materials supply. The value of these too is immense.

Climate change is also projected to have effects such as global sea-level rise and intensifying GLOBAL WARMING. According to a recent Arctic Climate Impact Assessment report (ACIA, 2004), the Arctic CLIMATE is warming rapidly, at almost twice the rate as the rest of the world in the past two decades. At least half the summer sea ice in the Arctic is projected to melt by the end of this century, along with a significant portion of the Greenland Ice Sheet. Climatic variations will have a large impact on marine environments and marine-related activities, including rising sea levels, changes in ocean salinity (which could strongly affect regional climate), the decline or extinction of marine species due to habitat loss, expanding marine shipping and the enhancement of some major Arctic fisheries together with the decline of others.

On 26 December 2004, the Indian Ocean tsunami devastated coastal communities. In its reports on the environmental impact of the Tsunami in Sri Lanka and Maldives, the United Nations Environmental Programme (UNEP, 2006) has noted that coastal areas where coral reefs, mangrove forests and natural vegetation had been removed suffered the greatest damage. Fishing communities were the worst hit. The challenges include not only the restoration of the livelihood of fishermen and raising the income of coastal communities above pre-tsunami levels, but also capacity building to improve skills of boat builders, enforcement of standards to reduce potential risks to fishermen, and the revival of the tsunami-hit aquaculture industry.
Oil

Oil. Petroleum, it is sometimes said, is the economic bedrock of our hydrocarbon civilization. The fuel of modernity, oil is an archetypal global commodity, the repository of unimaginable wealth (‘black gold’) and part of the largest business on Earth (see Capitalism). More than anything else, petroleum is a sort of lie: it reveals the profound mystification, the paradoxes and that contradictoriness that surround natural resources in our modern world.

If oil is a natural resource – arguably the most global, the most strategic and among the most valuable – what exactly is natural about it? It is a flammable liquid that occurs as a product of geophysical and biological processes of great historical depth. A by-product of pre-human geological history, oil is deposited in subterranean formations and consists principally of a mixture of hydrocarbons with traces of nitrogenous and sulphurous compounds. In practice, of course, the composition of what passes as petroleum varies quite considerably, as one might anticipate in view of the heterogeneous circumstances associated with its 600 million year history of sedimentation and organic decomposition. Oil’s natural properties, one might say, are unstable and variegated (see Nature).

Petroleum is customarily extracted through drilled wells, pumped along pipelines and refined into different ‘fractions’ or components. The science and practice by which oil is explored, located, pumped and fractionated has, in the past 150 years, deepened and proliferated to the point at which it is now part of a massive engineering and technical infrastructure. The oil industry is now dominated by the ‘majors’, a cluster of transnational and highly diversified energy companies (see Transnational corporations). It is sometimes said that oil drilling was invented by E.L. Drake, when he sunk his now infamous 69 foot well in Pennsylvania in 1859. But several hundred years before the birth of Christ, the Chinese were sinking 3500 ft wells to exploit petroleum for a multiplicity of purposes. Surface oil deposits had been used as asphalt and as a sealant by Sumerians 3,000 years before the Chinese. In other words, oil’s natural resource use spans a vast swathe of human history.

Currently, oil and related gas exploitation covers two-thirds of global energy needs: according to the International Energy Agency, by 2030 the figure will have fallen only marginally. Industrialized countries of the OECD account for almost two thirds of world oil demand. Global demand for oil is about 80 million barrels per day (compared to 47 million in 1970). The USA consumes by far and away the largest quantities of petroleum (roughly 25 per cent) and is extremely dependent on oil imports (largely from the Middle East, Canada and Mexico, and increasingly Africa). The geography of oil and gas has a distinctive geography: two thirds of known oil reserves reside in the Middle East (which is overwhelmingly Muslim, a fact that has assumed particular significance in the context of 9/11 and the US occupation of Iraq). Saudi Arabia, Iraq and Kuwait alone account for almost 500 billion barrels of reserves. Over three-quarters of all known reserves of petroleum are found in eight oil-exporting countries. The centrality of the USA in the global oil acquisition strategy – a fact sealed by the special relationship between the USA and Saudi Arabia, made in 1945 – has meant that the geopolitics of oil have been a central plank in US foreign policy over the past 80 years. The US addiction to cheap oil – which is to say to the automobile – turned, in the postwar period, on imperialist relations with three key suppliers: Saudi Arabia, Venezuela and Iran. By 2001, this policy had proven to be a catastrophic failure – even if the US consumer had benefited from oil prices at the gas station that bore no relation to actual costs of production (which necessarily would have to include the massive expenditures on the military and the costs of global climate change and other ‘externalities’).

The structure of the oil industry is characterized by a recent (post-1970) reorganization (Yeoman, 2004). The global oil and gas industry is dominated by five transnational oil companies (ExxonMobil, Chevron, Shell, BP and TotalElfFina) with combined revenues over $1 trillion, and a number of massive national oil companies (owned by oil-producing states). The assertive petro-nationalism of the 1970s saw national oil companies account for an increasingly large proportion of oil reserves, while transnational companies increasingly moved downstream to control refining and petrochemical sectors. Many of the world’s most important oil producers are petro-states, marked by an extreme dependence (measured as a proportion of exports or GDP) derived from oil and gas. Rentier economies of this sort are plagued by what has been called the ‘resource curse’ (Auty, 2001):

510
massive corruption, CONFLICT, poor social achievement, authoritarian politics and low economic growth (see Karl, 1999: see also RENT). Oil states, transnational companies, national oil companies, international financial institutions and various sorts of military and security forces combine to produce an ‘oil complex’ (Watts, 2005), which operates as a powerful system for dispossession and PRIMITIVE ACCUMULATION. Industrialized oil importers have been only too happy to build warm and friendly relations with corrupt petro-states, turning a blind eye to HUMAN RIGHTS violations and failed DEVELOPMENT, provided that the oil continues to flow.

Petroleum is the quintessential modern natural resource. It is present in and produced by nature, and a material source of wealth that occurs in a natural state. But this is a contradictory and non-sensible claim on its face. Oil is natural insofar as it resides in its Jurassic bedrock. But it is not immediately accessible or useful: it presupposes human knowledge and practice (drilling, exploring, refining). Oil’s wealth is not conferred solely by natural process, but rests upon an appraisal – a state of knowledge and practice – that is social, technological and historical. Petroleum is profoundly of nature – it is typically subterranean and has peculiar biophysical properties. And yet its naturalism is expressed and understood in quite determinate ways: how differently would the first-century BCE Chinese bureaucrat and the twentieth-century hard-rock geologist have described petroleum’s natural properties! Petroleum’s ‘resourcefulness’ is not natural at all. Its expressive form as wealth – the defining property of a resource – presupposes acts of transformation, distribution and use which, incidentally, were very different for sixteenth-century North American Indians than for a twenty-first-century Louisiana petrochemical industry. Petroleum as a natural resource rests, then, on particular meanings of natural (e.g. theories of biophysics), and particular renderings of resource (e.g. theories of wealth predicated on scarcity and natural limits).

But there is another realm in which natural resources must operate; namely, the social imaginary – in other words, how oil is rooted in the imagination of people living in the specific historical and social circumstances of its use and deployment (see GEOGRAPHICAL IMAGINARIES). Oil as a natural resource carries it own mythos, also shaped by PLACE and time. From the vantage point of the oil-importing North Atlantic economies, oil stands in a specific relationship to the mosque and the Arab world. For oil-producing states, petroleum provides the idiom for nation-building and the financial wherewithal for modern development (think, for example, of the petro-ambition of a great modernizer such as Shah Palavi in Iran). Oil is inextricably bound up with unimaginable personal POWER (Rockefeller, Nobel, Rothschild, the Sultan of Brunei), untramelled corporate hegemony (‘the Seven Sisters’) and a history of spectacular imperial VIOLENCE and WAR. Did not the long and dark tentacles of oil appear in the catastrophic demise of the twin Trade Towers in New York? Was not Osama bin Laden a product of oil as much as of Wahhabi Islam? Was not the Ayatollah Khomeini’s revolution in 1979 fuelled by oil-inspired resentments and grievances? Need one mention Enron? Oil and Islam, war and violence, corruption and power, wealth and SPECTACLE, scarcity and CRI-SIS are, in our times, seemingly all of a piece.

In contemporary America or Europe, oil is a particular type of commodity used, exchanged and fetishized in quite precise ways. It is a bundle of natural (biophysical), productive, cultural and economic relations. It is altogether appropriate to recall that petroleum is popularly referred to as ‘black gold’. But, after all, gold isn’t black. And neither are many forms of oil. They are colourless.

ontology The study and description of ‘being’, or that which can be said to exist in the world (cf. EPistemology). Although ontology has many definitions and approaches in PHILOSOPHY and in GEOGRAPHY, it tends to be formulated by considering interactions between the world as-it-is and ideas or conceptions about the world. Western thought has been greatly influenced by the classical, formal ontology of essences, exemplified by Plato’s Ideals (where objects in the world are imperfect copies of ideal forms) and Aristotle’s categories (where all such forms emerge inductively out of the stuff of the world). Concern with ontology in the natural sciences and the human sciences typically focuses less on the general conditions of existence than on the objects, relations and concepts serving as the foci of their specific disciplines. In this vein, the main ontological hobbyhorses in HUMAN GEOGRAPHY have included the character of the relations between SOCIETY and NATURE, and concepts of PLACE and SPACE.
 Ontological repositionings within human geography over recent decades have largely been a response to the scientific ontology of high modernism, the belief that the world is transparently knowable to the knowable observer. This approach, best exemplified by spatial science, is articulated through the philosophy of positivism and its derivatives: given enough information about objects and events in the world, it is possible to derive a series of scientific laws that account for or explain them. Such positions are predicated on the ontological assumption that the universe is a closed system whose movements are determined by a finite (albeit complex) set of causal forces and, further, that the objects making up the world are discrete, stable and categorizable (Dixon and Jones, 1998).

This reading also holds that both the general laws pertaining to causal forces and the essences or forms that demarcate discrete objects are themselves real and objective parts of the world ‘out there’, awaiting discovery.

Behavioural geography and humanistic geography, though sometimes falling back into versions of positivism, provided a critical response to these objectivist claims by gradually incorporating insights from non-positivist philosophies including philosophy, and by paying particular attention to the importance of variations in perspective produced through the experience, perception and lifeworld of the individual. Here, ontology is a matter of ‘being-in-the-world’, wherein the world reveals itself through the phenomena of experience. As such, the objectivity of positivism is replaced by an experiential subjectivism. This difference has often framed the distinction between space and place (Entikin, 1991).

The hints of perspectivalism within humanistic geography in particular found fuller fruition within feminist geographies, which critiqued spatial science for masking a masculinist epistemology under the name of ontology (see masculinism). While rarely making explicit ontological statements, the partial and situated standpoint of feminist theory (cf. situated knowledge) were not inconsistent with a Leibnizian ontology of proliferated, situated difference. Perhaps most importantly, this resulted in the ontological notion of relational space (Massey, 2005), a conceptualization of co-productive spatiality emerging with the mobile and mutable interactions between space and the human subject. Such entanglements point to dialectics (Harvey, 1996), an ontology of internal relations rather than external relations. In contrast to positivism, therefore, dialectical thought refuses discrete objects and events as things ‘in themselves’, and with this denies the separation of phenomena from experience, theory and politics. An ally in this mode of thought is the philosophy of critical realism, an ontology of levels aimed at understanding the causal powers of necessary and contingent social relations (Sayer, 2000).

With the advance of post-structuralism in human geography, ontology and its cousin metaphysics were increasingly critiqued as a series of epistemological constructs mired in cultural, political and, most importantly, linguistic and discursive imaginaries. Thus, the ontological distinctions formed in key geographical binaries such as nature–culture, order–chaos, time–space and individual–society could, under this epistemological critique, be called out as false dichotomies that reflect more the Western bias of either/or-ness than any serious reflection on the social construction of such categories. While the post-structuralists never denied that there was a real ‘out there’ in the world, they denied that it was possible to know it through some form of direct, pure experience (Deutsche, 1991). By this point, ontology itself became a target: the ‘real’ world, it was argued, was shut out from the observer by virtue of the very knowledges that constitute the ‘observer’ as such, as well as by the culturally inflected modes of representation at hand to describe it. In a similar vein, human geographers influenced by post-structuralist renderings of psychoanalytic theory, particularly those arising out of the work of Lacan and Zizek, drew from suggestions that immersion in language and symbols makes access to the ‘Real’ impossible.

Despite the aversion to ontology during the epistemological turn of the 1990s, however, interest in the topic has re-emerged in human geography in large measure through the growing popularity of the works of Gilles Deleuze. Drawing largely upon Baruch Spinoza, Deleuze (1994) creates a ‘flat’ ontology of ‘pure difference’ by theorizing becoming, multiplicity and differentiation as ontologically antecedent to the traditional foundations of being, categoricality and sameness, thereby rejecting long-held conceptual centrepieces. Here, being, models, structures and categories are not the stuff of ontology proper, but are rather the results of the way that thought deals with difference and continuous differentiation (i.e. by producing orders of similitude). Deleuzean ontology is not a search for transcendental objects, structures and forms...
making up the world, but an immanent material self-organization that allows for the possibility of new types of things to come into the world. This work has been highly influential for recent theoretical experimentations in human geography, providing perhaps the fundamental ontological support for NON-REPRESENTATIONAL THEORY (Deleuze himself had been treating the non-representational ontologically since the 1960s) and for elaborations of ACTOR-NETWORK THEORY (for re-theorizations of human–nature relationships).

opportunity costs An important concept in NEO-CLASSICAL ECONOMICS, with the costs of an action expressed as opportunities foregone – usually in monetary terms. If rural land is set aside as a nature reserve, there will be costs to both the landowner and society in terms of the net value of the agricultural products not produced: similarly, a commuter may see the cost of travel time as earnings foregone. The concept can therefore be used in explaining the allocation of productive resources between competing activities, especially where they are in short supply. It plays an important role in theories of RENT, COMPARATIVE ADVANTAGE and LINEAR PROGRAMMING.

optimization models Mathematical models that are used to search for the optimal solution to a problem. These MODELS have a quantity to be either maximised or minimized, known as the ‘objective function’, such as the minimization of total transport costs or the maximization of a firm’s profits, together with a set of constraints that limit the range of possible solutions, such as limits on supply and demand, or the capacity of transport routes. LINEAR PROGRAMMING is the most widely used form of optimization, but the models may take a great variety of mathematical forms and many spatial applications (such as optimal location decisions) involve non-linear forms.

Orientalism The term ‘Orientalism’ has three main meanings. The first two involve (i) the scholarly study of the Orient, and (ii) a more general (and especially aesthetic or cultural) interest in the Orient. But neither of them pays much attention to the possibility that the object of their interest – ‘the Orient’ – is itself a predominantly European and American construction produced within a specific grid of POWER and knowledge (cf. OCCIDENTALISM). This is the focus of the third definition proposed by the Palestinian/American literary critic Edward Said (1935–2003): Orientalism as (iii) both a Discourse and a ‘corporate institution’ for the production and domination of ‘the Orient’ (Said, 1978, p. 3). It is this definition that has attracted most attention in HUMAN GEOGRAPHY, but it is important to notice Said’s double emphasis on production and domination: representations of ‘the Orient’ often have the most acutely practical, material consequences (cf. PERFORMATIVITY).

Said acknowledged that Orientalism in this third sense has a long and tangled history, but he focused on the specifically modern apparatus of power-knowledge that emerged towards the end of the eighteenth century. His proxy for this was the Napoleonic occupation of Egypt (1798–1801) and, in particular, the Description de l’Égypte produced by the scholars who accompanied the expeditionary army. Said’s emphasis on the materiality of power-knowledge is also significant. While he was keenly interested in the production of IMAGINATIVE GEOGRAPHIES of ‘the Orient’, Said insisted that Orientalism was not ‘an airy European fantasy about the Orient, but created a body of theory and practice in which, for many generations, there has been considerable material investment’ (1978, p. 6; emphases added).

What gave Orientalism its peculiar power was that it was produced from the outside and marginalized or silenced the voices of those who were its collective subjects: ‘What gave the Oriental’s world its intelligibility and identity was not the result of his own efforts but rather the whole complex series of knowledgeable manipulations by which the Orient was identified by the West’ (p. 40). It was this, above all else, that implicated Orientalism in the operations of colonizing POWER, because it made ‘the Orient’ appear as ‘an essentialized realm originally outside and untouched by the West, lacking the meaning and order that only colonialism can bring’ (Mitchell, 1992, p. 313). For Said, then, Orientalism operated both in advance and in conjunction
ORIENTALISM

with COLONIALISM, underwriting colonial power through two crucial operations:

- First, ‘the Orient’ was constructed as an exotic and bizarre space, and at the limit a pathological and even a monstrous space: ‘a living tableau of queerness’ (Said, 1978, p. 103).

- Second, ‘the Orient’ was constructed as a space that had to be domesticated, disciplined and normalized through a forceful projection of the order it was presumed to lack: ‘framed by the classroom, the criminal court, the prison, the illustrated manual’ (Said, 1978, p. 41).

It is not difficult to hear the echoes of Michel Foucault’s archaeologies and GENEOLOGIES in these arguments, though Said was perplexed (and vexed) by the French philosopher’s metropolitan obsession and his disinterest in the operations of colonial power (Gregory, 1995b).

Said’s critique of Orientalism was closely connected to his political commitment to the Palestinian cause, and his work has met with vigorous criticism from Right and Left. Theoretically, critics have been exercised by the complicity of Said’s HUMANISM with the very tradition that he criticizes (Sardar, 1999, p. 73); by his conjunction of humanism with Foucault’s ANTI-HUMANISM (Clifford, 1988); by his complicated relationship with HISTORICAL MATERIALISM (Ahmad, 1992); and by his seeming inability to break out from the binary oppositions of Orientalism itself (Young, 1990b). Substantively, others have criticized Said’s readings and substituted more affirmative interpretations of some contributions to the Orientalist canon (Livingstone, 2004; Irwin, 2006).

Much of this discussion comprises variations on the theme of ESSENTIALISM. Said is charged with reducing the complexity of European and American engagements with other cultures to a single, totalizing essence that projects its will to power upon them. Other scholars, including Said himself, have sought to meet this objection by developing a more nuanced analysis of Orientalism. Their key propositions include the following:

(1) Orientalism is not a synonym for colonial discourse. There are overlaps with other colonial discourses, but different imaginative geographies were fashioned for different places and periods: see PRIMITIVISM and TROPICALITY. Indeed, Said (1993) subsequently extended his enquiries to the wider relations between CULTURE and IMPERIALISM in the nineteenth and early twentieth centuries.

(2) Orientalism is not cut from a single cloth: there are different Orientalisms and different ‘Orients’. The substantive focus of Said’s original enquiry was not ‘the Orient’ at large but the MIDDLE EAST in general and Egypt and Palestine in particular. It is important to recognize other versions of Orientalism developed in relation to (for example) India, China and Japan.

(3) There are significant differences between the collective authors of Orientalism. Said focused on British and French Orientalisms because they had such a close connection with colonialism, but other scholars have drawn careful distinctions between (for example) American, British, French and German Orientalisms.

(4) Orientalism is not a simple projection of the will to power. Power, including the power of REPRESENTATION, did not lie entirely with the outsider and the colonizer, and a more nuanced view of the contact zone is required that can recognize TRANSCULTURATION and the achievements of anti-colonial struggles. Said accepted this criticism, but Sardar (1999, pp. 74–5) noted that his commitment to a secular humanism allowed little space for Islam as a counter-discourse.

(5) Orientalism is a gendered and sexualized discourse. Said was more interested in Orientalism’s feminizing metaphors (‘the Orient as woman’), but feminist scholars have examined how GENDER and SEXUALITY entered into the experiences and practices of travellers, artists and writers operating under its sign (Melman, 1992; Yegenoglu, 1998).

(6) Orientalism produced other ‘natures’ as well as other ‘cultures’. Like Oriental CULTURE, Oriental NATURE was often constructed as an ‘unnatural nature’, capricious and extreme, to be domesticated, disciplined and normalized through Euro-American cartographic, scientific and engineering projects (Gregory, 2001b).

(7) Orientalism is not confined to texts. Said’s field was comparative literature, so it is scarcely surprising that he focused on the written traces of high culture, but other scholars have focused on other modes of REPRESENTATION (including art and photography) and its involvement in mundane practices such as travel and TOURISM (Gregory, 1999).
Most of these critical elaborations have been historical, but the spectre of Orientalism still haunts the present. Its imaginative geographies have been activated in two new rounds of demonization of the ‘Oriental Other’. First, a techno-Orientalism has been directed against the economic rise of Japan and, more recently, China, which have both been represented as threats to the global economic power of Europe and the USA (Morley and Robbins, 1992). Second, a neo-Orientalism has been mobilized in the ‘war on terror’ against political actors, groups and organizations in the Middle East, and against Arab and Muslim communities in Europe, North America and Australia (Tuastad, 2003; Gregory, 2004b: cf. TERRORISM). These new activations have an insistently practical dimension too, which is by no means confined to grand strategies and political or military campaigns. Haldrup, Koefoed and Simonsen (2006) identified the rise of a practical Orientalism grounded in the corporeal encounters and routines of Everyday Life, in which Orientalist versions of the friend/enemy distinction are reproduced through the countless ‘small acts’ and stories that make up the intimacies of everyday life. Seen thus, the critique of Orientalism is far more than a theoretical or textual affair: it is also a profoundly political and practical project. DG

Other/Otherness The Other is that which is excluded from the Self and through this exclusion comes to constitute the boundaries of the Self. In Phenomenology of spirit (1807), G.W.F. Hegel introduced the master/slave DIALECTIC, which founded an idea of the ‘Other’ that has since been absorbed from continental PHILOSOPHY into the social sciences and GEOGRAPHY. Simone de Beauvoir built upon the Hegelian master/slave dialectic, in which a hierarchical dualism defines a superior position in relation to an inferior one, to show how women has been constituted as the Other to man. As long as women remain locked in this relationship, de Beauvoir argued, they cannot become subjects in their own right (see SUBJECTIVITY). For both Hegel and de Beauvoir, true freedom requires a struggle in which the Other comes to risk her life. The MASCULINISM of the Self/Other binary has been taken up in FEMINIST GEOGRAPHIES to show how some kinds of geographical knowledge have been privileged over others.

The idea that the Self is defined in relation to Others is also a key component of PSYCHOANALYTIC THEORY. According to Jacques Lacan (2002), the ‘mirror stage’ of infancy occurs when the child first realizes that what he had until then experienced as fragmented is in fact his ‘self’. Following this recognition comes a desire to delimit these boundaries and thereby to maintain the Self through the exclusion of the Other. Drawing upon the work of Sigmund Freud, the relationship between one’s self and the objects of the world has come to be referred to as ‘object relations theory’. Geographers have drawn upon these ideas to show how the Self is a cultural production that relies on socio-spatial practices of inclusion and exclusion.

The Self/Other duality has come to inform POST-COLONIALISM, FEMINISM and their intersection. In his critique of ORIENTALISM, Edward Said (2003 [1978]) showed how European and American representations of ‘the Orient’ have worked to constitute the self-identity of the West as superior to the East. Bringing Said’s critique together with feminist theory, others have shown how the interlocking hierarchies of RACE, CLASS and GENDER have been constitutive of both imperial relations and domestic social structures. In other words, hierarchical dualities of Self and Other (West and East, man and woman, human and less-than-human) have been shown to be the building blocks of Western MODERNITY. ‘[I]t is only insofar as “Woman/Women” and “the East” are defined as Others, or as peripheral, that (Western) Man/Humanism can represent him/itself as the center. It is not the center that determines the periphery, but the periphery that, in its boundedness, determines the center’ (Mohanty, 1991, pp. 73–4).

Geographers have shown how the Self/Other duality has worked to produce and delimit geographical knowledge. For example, Derek Gregory (2004b) has built upon Said’s work to show how everyday cultural practices work to produce spaces of ‘the same’ and spaces of ‘the other’ at the global SCALE. Gregory shows how some peoples are represented as occupying a space ‘beyond the pale of the modern’, and therefore to have forfeited the rights and dignity associated with Western MODERNITY and HUMANISM (p. 28).

outsourcing A mode of business organization that has become increasingly common...
since the 1980s, in which businesses contract with third-party subcontractors to provide product components and business services such as accounting and customer relations. Whether or not it is explicitly discussed in terms of post-Fordism, the recent explosion in subcontracting and business-to-business (‘B2B’) networking is widely associated with the pressures to abandon Fordist models of vertical integration and develop more flexible, market-mediated business practices in the context of globalization. For the same reason, outsourcing is often used synonymously with ‘off-shoring’ in political discourse. In his 2004 campaign for the US presidency, for example, Senator John Kerry assailed outsourcing by talking about ‘Benedict Arnold corporations’. The implication in this analogy with the eighteenth-century American traitor (who had planned to surrender the American fort at West Point to the British) is that outsourcing by US companies is a betrayal of American independence. But outsourcing need not necessarily involve sourcing from foreign suppliers, and in fact is often based on localized regional supply networks. Indeed, economic geographers who study these networks are interested in the ways in which they both depend upon and foster forms of spatial agglomeration, because the economic ties of outsourcing supply chains necessitate diverse social and cultural ties – ‘untraded interdependencies’, as one leading researcher calls them (Storper, 1997b) – in order to function effectively. That said, even some of these clustering effects have been transnational in scope; for example, between Western European clothing retailers and Eastern European suppliers (see Smith, A., 2003a). More generally, the increasing turn to sourcing from foreign companies (from Infosys in India, for example) has captured the public imagination in North America and Western Europe since the 1990s (e.g. Engardio, 2006). Consequently, for critics, outsourcing has become widely associated with the downward pressures on wages and benefits that make the corporate search for sourcing efficiency synonymous with a global race to the bottom.

Since 9/11, outsourcing has been used in arguments against ‘extraordinary rendition’ — the clandestine US policy of sending suspected terrorists abroad to be violently interrogated by third parties in countries such as Egypt and Syria (Smith, N., 2006a). There are obvious differences between this externalization of interrogation and torture by government and the externalization of business activities by transnational corporations, but neo-liberal commonalities underlie them, including the use of private logistical services (such as rented business jets) as well as the unaccountability in the use of foreign third parties (Sparke, 2006). By decrying extraordinary rendition as the ‘outsourcing of torture’, critics have suggested in turn that it combines a sort of penal race to the bottom with a twenty-first century betrayal of American liberty (Mayer, 2005).

overpopulation The idea that the size, density or organization of an area’s population is too great to be sustained. Neo-Malthusian work argues that increased population reduces an areas’ resource base until the carrying capacity is breached (see limits to growth; malthusian model). However, neo-Marxist scholars have countered that overpopulation makes a structural contribution to the continuation of certain modes of production, as an increased supply of potential workers reduces wage rates (Harvey, 1974a). The associated terms over-urbanization and over-ruralization have sparked considerable debate, with recent work on China supporting a transition from an under-urbanized to an over-urbanized society (Shen, 2002).

Suggested reading
Pacific Rim A geographical region stretching across the Pacific Ocean and incorporating the westernmost cities of North America in addition to Japan, Australia, and the coastal cities and city-states of East Asia. The term became prominent in the 1980s as a result of Asia’s increased economic power and the intensification of cross-Pacific trade and financial linkages (Appelbaum and Henderson, 1992). Academic and popular writings on the region became so saturated with hyperbole that many critics began to argue that the region was itself a literary creation – one that served the economic agendas and geopolitical visions of a pro-laissez-faire Euro-American audience (see, e.g., Dirlik, 1993).

Appelbaum and Henderson (1992); Dirlik (1993).

Pandemic A term (derived from the Greek pan-, all + demos, people), used in the health sciences to describe the occurrence of a specified illness, health behaviour or other health-related event that is unusually prevalent (epidemic) over an extensive geographical area. The term is often applied to periods associated with the international spread of major human infectious diseases such as cholera, influenza, plague and smallpox (e.g. ‘pandemic influenza’; see Patterson, 1986), with the expression ‘global pandemic’ reserved for periods of rapid worldwide transmission of a disease agent. Global pandemic events of the past 100 years include ‘Spanish’ influenza (1918–19), El Tor cholera (1961–) and the Acquired ImmunoDeficiency Syndrome (AIDS) (1981–); see Kohn (1998). (See also biosecurity.)

Panopticon Philosopher and jurist Jeremy Bentham’s design for a building, most commonly a prison, in which centralized power is all-seeing – *pan-opticon* – is described in his book of that title (1791; see Bentham, 1995). Bentham’s design was for a circular building, with rooms arranged around the circumference, open at both ends, of one or more storeys. The individual rooms, or cells, would thus be illuminated from behind, and visible at the front to a central tower. The occupant of the tower would thus be able to look into each and every cell from a fixed position. However, it would be possible to construct a system of blinds that prevented the occupants of the cells from seeing into the control tower, and so they would be unaware if they were being observed at that point or not, or even if there was an occupant in the tower. Not only would they therefore be subject to external power, they would turn that power on to themselves, being self-disciplining. Bentham’s design was suitable for any building in which it was necessary or useful to be able to continually observe individuals who would have no contact with the other occupants, such as a school, a factory, a hospital, barracks, a poor-house or, most commonly, a prison. Bentham’s design was offered to the British government as a model for the prisons being constructed as transportation to the colonies became less viable in the late eighteenth and early nineteenth centuries, but was only taken up in part in model prisons such as Pentonville and the Millbank Penitentiary. Panopticons were also built outside Britain, including in Spain, the Netherlands, the USA and Cuba.

Bentham’s model assumed a wider contemporary significance as a result of Foucault’s 1976a [1975] analysis of the Panopticon as an exemplar of disciplinary power (see Patton, 1979). Foucault saw the Panopticon as the architectural conjunction of two models of dealing with social problems, which he analysed as the problem of lepers and the problem of the plague. With leprosy, victims were excluded from society; with the plague, they were rigidly controlled from within. While ‘the leper gave rise to rituals of exclusion . . . the plague gave rise to disciplinary diagrams’. In a plague town there was a strict spatial partitioning, with careful surveillance, detailed inspection and mechanisms of ordering. These illustrate two models: a pure community as opposed to a disciplined society. Both are symbols of wider models of power, as is the Panopticon in Foucault’s analysis. It is the architectural fusion of these models, where the organization of the plague town is brought
to bear on the spaces of exclusion. Foucault suggested that the society that emerged in this period can be better understood as one of generalized \textit{panopticism}, where the ideal of surveillance and ordered behaviour is spread through cities as a whole. Foucault’s analysis has not been without its critics, but his account, together with his re-edition of the French text with an introductory interview (1980d), helped to bring Bentham’s work back into discussion. In \textit{Human Geography}, Foucault’s arguments have influenced historico-geographical studies of poverty, welfare and workhouses (Driver, 1993) and contemporary critiques of security, surveillance and incarceration (Hannah, 1997; Dobson and Fisher, 2007).

\textbf{paradigm} An old English word meaning pattern, exemplar or model, but rescued from obscurity by the American philosopher and historian of science Thomas Kuhn (1922–96) in his short monograph \textit{The structure of scientific revolutions} (1970 [1962]), reportedly the most cited book of the twentieth century. The precise definition of ‘paradigm’ is contentious, with one critic counting 21 different meanings in the first edition of Kuhn’s book (although the second edition offered clarification: Masterman, 1970). Roughly, a paradigm is the constellation of values, assumptions, methods and exemplars shared by a given scientific community, making it what it is. A paradigm shapes what scientists think about something before they think it.

Kuhn’s use of ‘paradigm’ was part of his larger project to provide an alternative to the traditional history of science that stressed science’s progressive and heroic character. For Kuhn, most science was puzzle-solving, with practitioners working within a common frame of reference, shared assumptions, techniques and standards; that is, a paradigm. Consequently, the activities of scientists were run of the mill, not heroic. Within this framework of \textit{normal science}, however, anomalies occurred that could not be explained within the prevailing paradigm. Given enough of them, a crisis eventuated, precipitating \textit{extraordinary research} (not mere puzzle-solving). If successful, in the sense that the new research accommodated the anomalies, revolutionary change occurred in the form of a \textit{paradigm shift}, setting the blueprint for the next period of normal science. Paradigms, however, by their very constitution, were incommensurable.

Scientific knowledge, therefore, moved not as linear progress, but as incomparable, discontinuous transformations (‘scientific revolutions’).

Kuhn’s work garnered an enormous amount of critical attention. There were the definitional ambiguities already mentioned. Kuhn’s response was to clarify ‘paradigm’ by separating out the global characteristics of a scientific community, labelled the ‘disciplinary matrix’ (Kuhn, 1970 [1962], p. 182), from ‘concrete problem solutions’ (Kuhn, 1970 [1962], p. 186) such as the use of a particular book or mathematical technique, termed ‘exemplars’ (Kuhn, 1970 [1962], pp. 186–7). Other criticisms went to his substantive claims. Toulmin (1970) argued historically that paradigm change was not revolutionary, but occurred all the time. The rarity was normal science. For this reason, Popper (1970, p. 53) thought that ‘one ought to be sorry for’ Kuhn’s ‘normal scientist’. Likewise, Kuhn’s thesis of incommensurability drew fire with its implication that science does not progress. Lakatos (1978), while accepting incommensurability between ‘hard cores’ of rival theories, claimed that one could still meaningfully speak of progress using empirical prediction and corroboration to construct research programmes.

These are important points, but they do not help us to understand why Kuhn’s book was such a runaway success. There are many reasons, but the most important was its anti-rationalism, and its resonance with a similar sentiment washing over a number of \textit{humanities} and social sciences from the 1960s (where the book was read much more than in science), and culminating in \textit{postmodernism} and \textit{post-structuralism}. Whether he meant to or not (and the evidence is that he did not), Kuhn represented scientific knowledge not as an unsullied, abstract form of rationality (the progressive, heroic view), but relativistically as mired in context-specific cultural beliefs and ordinary practices, in paradigms. Not that this was the interpretation of paradigm by geographers who first made use of Kuhn during their own ‘scientific revolution’, the self-styled \textit{quantitative revolution} that was to usher in \textit{spatial science} through ‘extraordinary research’. Perversely Kuhn’s ‘paradigm’ was interpreted as a justification for that movement’s rationalist scientific approach (Haggett and Chorley, 1967) and paradigms were treated as scientific models (cf. Billinge, Gregory and Martin, 1984a; Mair, 1986). Some later exponents, however, tried to
recoup some of the radical anti-rationalist possibilities of Kuhn's work through interpretations of the discipline's history (Barnes, 2004b). But while Kuhn's book might have been on the *Times Literary Supplement*’s list of top 100 most influential books since the Second World War, it was never on geography’s top 100 list. Even so, ‘paradigm’ is no longer an obscure term, and is now widely used to mean ‘exemplar’ or, in a much looser sense than Kuhn intended, to describe a more or less systematic way of thinking about or doing something.

**Pareto optimality** A situation in which it is impossible to make some people better off without making others worse off. This criterion of ‘economic efficiency’ was devised by the economist and sociologist V.F.D. Pareto (1848–1923), and is an important element in neo-classical economics. The Pareto criterion may be applied to efficiency of resource allocation, optimality being achieved when it is impossible to reallocate resources to produce an outcome that would increase the satisfaction of some people without reducing the satisfaction of others.

The attainment of Pareto optimality is illustrated in the figure. Resources are available to generate a certain amount of income distributed among A and B – these could be individuals, groups of people or even the inhabitants of two different territories. The line AB indicates the possible distributions of the maximum total income available, ranging from all going to A and none to B (at point A) to all going to B (at B). Point X is a position of Pareto optimality, where any redistribution in the direction of either A or B (along the line) will make the other party worse off. In fact, any starting position on the line is Pareto-optimal. It would be impossible to increase A's share from X to Z (thus leaving B in the same position) because this conflicts with the resource constraint. However, point Y inside the triangle ABO is sub-optimal by the Pareto criterion because available resources are not fully utilized and it is possible to increase A's income to X, for example, without taking anything away from B. Such a move would be a ‘Pareto improvement’.

The Pareto criterion figures prominently in traditional welfare economics, where it is argued that acceptance of Pareto optimality as a rule for allocative efficiency or distributive equity involves minimal ethical content. However, adoption of the Pareto criterion carries some important implications that tend to strengthen the status quo. Once society has reached the limit of production possibilities – that is, there is no more growth – then the poor cannot be made better off without conflicting with the Pareto criterion, for any such move would be at the expense of others (the rich). Thus however badly off the poor may be, they can be made better off only if more income (or whatever) is produced. In practice, the application of the Pareto criterion in a no-growth economy would prevent redistribution in the direction of the poor, no matter how unequal the existing distribution (cf. welfare geography).

**participant observation** A research method in which the researcher aims to participate in the process under study so as to gain intimate knowledge of subjects and their habits, which insiders to a realm of practice might not otherwise reveal – or be able to reveal – in contrived situations such as interviews. Participant observation was a valued technique for the ethnographies of the Chicago School of urban sociology, as well as for the social anthropologists Bronislaw Malinowsky and E. Evans-Pritchard, and the cultural anthropologist Margaret Mead. As Malinowsky famously put it, participant observation provides a means ‘to grasp the native’s point of view, his relation to life, to realize his vision of his world’ (1961, p. 25), which would then have to be analysed in broader institutional terms through intellectual resources that the anthropologist considered to be ‘far surpassing the natives’. This gendered and colonial defence of expertise
PARTICIPATORY DEMOCRACY

has come under strong critique, not least within anthropology. However, attentiveness to the quality of relationships necessary to access contextual knowledge, the central concern of participant observation, remains central to a post-positivist or hermeneutic social science.

Michael Burawoy (see Burawoy, Burton, Ferguson and Fox, 1991) frames participant observation against both POSITIVISM and cultural RELATIVISM, as a method defined along two axes: a scientific or theory-data axis, which arrays objects from self-evident to subjects of theoretical scrutiny, and a hermeneutic axis, which arrays ‘observer’ and ‘observed’ across a range from estrangement to immersion. Burawoy stresses the importance of choice in locating oneself across both axes in the process of ethnographic research (see ETHNOGRAPHY). Self-consciousness about location in both these senses is crucial in analysis of what Donna Haraway (1991c) calls SITUATED KNOWLEDGES: products of perpetually tenuous relationships that cannot be resolved by claims to objectivity through familiarity or the crypto-religiousity of omniscient science.

Burawoy’s analytic can be pushed farther by asking how objectification on the scientific axis presumes the translation of only some aspects of local knowledge into ‘universal’ science, through specifically raced and sexed practices of intimate affiliation. As Hugh Raffles (2002) eloquently argues, most local knowledge remains in the not-universal, not-scientific, ethnographic context: a realm of intimate knowledge that is embodied, spatialized, affective (see AFFECT) and relational. Raffles’ challenge is to represent this broader affective geography through attention to multiple forms of participant theorization, on differentiated terms set by unequal access to broader intellectual, social and spatial resources. A key challenge of participant observation today is to find ways of representing the political economic, cultural, textual and affective resources through which knowledge is actually negotiated in context. This method can then defend the way in which specific products of participant observation become scientific evidence, not through Malinowsky’s suppression of subjugated knowledges, but through norms of accountability that contend with the unequal conditions of production of scientific knowledge. Such an approach also allows for ongoing claims to responsibility and redress for human subjects and their geographies, through evidence that explicitly shows reliance on the nature of ‘participation’.

PARTICIPATORY DEMOCRACY A system of government in which those being governed participate directly in decision-making and/or policy formation. It is contrasted with representative democracy, in which those being governed elect representatives to an assembly that takes decisions on behalf of the voters. Participatory democracy is usually thought to have originated in ancient Athens, where decisions were made by an assembly comprising all citizens. Although full participatory democracy is difficult to implement for large populations, popular participation in decision-making remains an aspiration for many social movements. However, COMMUNITY participation in governance has also been criticized for its association with neo-liberal policies (Herbert, 2005). (See also RADICAL DEMOCRACY.)

PARTITION In recent times, the idea of partition (connected to the interaction between competing diverse notions of statehood and nationhood) has attracted fresh attention as the inevitable, though not ideal, solution to protracted ethnic conflicts. Before the First World War, partition was a tool of the empires, dividing territories between themselves or using them to strengthen their rule. After the war, partition took place either in the devolution of authority granting independence to NATIONS or as a solution to ethnic conflicts perceived to be irreconcilable. Even then, the ‘solutions’ proved to be volatile and precarious since the TERRITORIES they created were not culturally homogeneous, as the partition of Palestine through the creation of the state of Israel or the successive partitions of India and Pakistan (with East Pakistan eventually becoming Bangladesh) have shown. In the ‘short partitions’, such as Vietnam and Germany, the nationalist journey might succeed without much difficulty, whereas in the ‘long partitions’, (marked by a long history of the politics of OTHERNESS and its persistence) the nation often fails the STATE. The project of harmonizing the nation with the state becomes nearly impossible.

According to a critical geopolitical perspective, ‘partition’ is not the end (product) of a geopolitical conflict or rivalry but, rather, a means of resolving or managing that conflict, accepted by various parties either as a matter of choice, or due to persuasion or pressure. In other words, partition is to be seen not as an inevitable consequence of actual or imagined predestined differences but, rather, as a
PASTORALISM

consciously developed and deliberately deployed spatial strategy of eliminating real or imagined differences – a method preferred over other methods, including ‘mutuality/consociation/power sharing’.

A comparison of partitions around the world, from British India to Yugoslavia, from Canada to Ireland, from Nigeria to Rwanda, from the Soviet Union to Palestine, appears to suggest that territory is, in fact, a crucial factor in the process of disrupting and reshaping states and loyalties. It is further revealed that the process of partition cannot be reduced to a state separation event (as in the cases of India and Pakistan, Serbia and Croatia, Ireland and Britain or potentially Canada and Quebec). This process also has to deal with additional regional sub-partitions, family divisions and religious contrasts. Partitioning British India, for instance, has generated a subsequent partition of Punjab and Bengal. Similarly, the partition of Yugoslavia has implied the sub-partition of Istria, Krajinas and Sandzak, and of Yugoslav populations and minorities.

Historically, there are very few examples of partition where violence could be avoided. Wherever and whenever partitions have been implemented, a large-scale destruction of the sociocultural landscape has invariably followed. In the vast majority of cases, violence becomes a determinant for reconfiguring political societies, where territory (or geopolitics), sources of loyalty and collective/individual psychology are forced to reshape and modify. To a certain extent, the stronger the pre-existing ties, the greater is the deployment of violence to construct new sources of identifications by redrawing maps. Among several icons of ‘partitioned times’ on the Indian sub-continent are millions of refugees who continue to live with bitter memories of loot, plunder, rape and murder, and in whom such memories live.

pastoralism Social and economic systems of peoples who both practice and strongly identify with livestock husbandry (most commonly of camels, cattle, goats and sheep). Identities of ethnicities, castes or lineages to livestock husbandry have typically formed historically during periods of occupational specialization. Mobile forms of pastoralism require fundamentally different demands on knowledge, social connections and labour than sedentary productive pursuits. Therefore, more mobile forms of pastoralism have been most associated with the occupational specialization tied to identity formation. For this reason, common uses of the term ‘pastoralism’ often suggest systems of herding specialists relying on more mobile forms of animal husbandry. However, pastoralism encompasses systems of variable reliance on livestock production and on livestock mobility.

From a CULTURAL ECOLOGY perspective, pastoralism is an effective adaptation to ECO- SYSTEMS that are marginal for crop agriculture due to soil, topography or climate constraints. Thus, while historically not necessarily the case, contemporary pastoralism is increasingly found largely within marginal areas, due to agricultural encroachment in productive areas. More mobile forms of pastoralism are seen as ideally suited for environments with significant spatio-temporal heterogeneity of vegetative productivity. Two axes of mobility within pastoral systems are human and livestock mobility. Nomadic pastoralism (see NOMADISM) involves the movement of pastoral families and their livestock, which does not allow the establishment of a permanent human dwelling. There are many other mobile pastoral systems, such as TRANSUMANCE, in which the whole production unit (family, clan etc.) does not move with the animals. Studies have found that the mobility of pastoralists is highly variable (over time and between production units), making categorizations of pastoral peoples based on their mobility and that of their livestock extremely hazardous.

Despite widely held romantic visions of isolated, individualistic pastoralists relying solely on their animals to meet subsistence needs, most pastoralist societies have historically aligned themselves to broader military/political authority for security and have relied variably (depending in part on livestock ownership) on farming and/or trade to procure grain and cash. This engagement with broader political and economic systems has become more evident since the mid-twentieth century in many parts of the world. More mobile pastoral livelihoods have generally not only not had the support of NATION-STATES, but have, in certain contexts, been actively attacked and dismantled by states that see pastoral mobility as working against their DEVELOPMENT and political aims (see MIGRANCY). Resource dispossession along with the economic vulnerability of livestock producers to market and climate fluctuations has led to increased impoverishment of pastoral peoples. While many pastoralists maintain identities tied to animal husbandry,
their livelihoods often depend more on other economic pursuits.

**patenting** Patents are a category of **intellectual property rights** designed to provide inventors with legal rights for a fixed period (usually 20 years) to prevent others from using, selling or importing their innovations. An application for a patent must satisfy a national and/or international patent office that the invention described in the application is new, useful and that its creation involved an inventive step either beyond the present state of the art or unobvious to a skilled practitioner.

Over time, more and more things (e.g. certain biological materials) have become patentable as business interests (and especially recently the life science firms involved in producing medicines) have successfully argued that patents are essential for their ability to make a return on the high R&D investment required to discover, produce and get regulatory approval for new products. Such an extension is reflected in the TRIPS (Trade-Related aspects of Intellectual Property Rights) agreement administered by the World Trade Organization (WTO) and is hugely controversial.

**patriarchy** A system of social structures and practices through which men dominate, oppress and exploit women. A distinction is made between classic or paternal patriarchy, a form of household organization in which the father dominates other members of an extended kin network (including younger men) and controls the economic production of the household, and fraternal patriarchy, in which men dominate women within civil society; the latter provided a key focus for feminist theorizing and organizing during the 1960s and 1970s. By the 1980s, the utility of the concept was in doubt; critics saw it as ahistorical and insensitive to cross-cultural variation. Efforts to theorize patriarchy in relation to capitalism seemed to collapse into functionalism, or leave the relations between the two systems unresolved. And if patriarchy operates autonomously from capitalist relations, as posited by **dual systems theory**, did this not leave the patriarchal relations of capitalism under-theorized? In geography, efforts were made by Foord and Gregson (1986) to resolve these dilemmas through **realism**: Walby (1989) criticized their model for neglecting paid work, the state and male violence (for other critical reactions, see gender and Women and Geography Study Group, 1997), and posited a dual systems theory of patriarchy at three levels of abstraction – system, structure and practice. Patriarchy, according to Walby, is composed of six structures: the patriarchal mode of production, male violence, patriarchal relations in paid work, the state, sexuality and cultural institutions. But in Acker’s view (1989), the moment of theorizing patriarchy in this way had passed: the object of feminism had moved from patriarchy as a system to gender relations (and now heteronormativity and sexual difference: see gender). Interest had also moved away from delineating the cause(s) of patriarchal relations to understanding the diversity of effects.

As early as 1980, Barrett suggested that patriarchy is better conceived as an adjective than as a noun. The term is still used as a noun, but typically in the plural: Grewal and Kaplan (1994, pp. 17–18) urge the need ‘to address the concerns of women around the world in the historicized particularity of their relationships to multiple patriarchies as well as to international economic hegemonies’, but their concern is to compare ‘multiple, overlapping, and discrete oppressions’ and not to construct ‘a theory of hegemonic oppression under the unified sign of gender’ (i.e. under the sign of patriarchy). Post-colonial theory has alerted feminists to the ways in which accusations of patriarchal relations among immigrant groups or in countries in the global South can be used to discriminatory, colonial or imperialist ends. The Bush administration’s justification of the US invasion of Afghanistan in 2001 – as in part a defence and liberation of Afghan women – is one example. Young (2003a) asks Western feminists to consider how they ‘laid the ground work’ for the success of this appeal through their own campaigns against the Taliban and the ‘stance of protector’ that they sometimes adopt ‘in relation to . . . women of the world who [Western women] construct as more dependent or subordinate’ (p. 3) and more oppressed by patriarchal relations.

**Pax Americana** Also known as ‘Pox Americana’, this synonym for **American Empire** makes parallels with the ancient Roman Empire to either critically unpack (e.g. Johnson, 2003a; Foster and McChesney,
2004) or uncritically expound (e.g. Steel, 1967) the argument that US global dominance makes the world safe for long-distance trade, communication and democracy. Most recently, it has been put forward by the National Intelligence Council (NIC; the US government’s ‘strategic intelligence’ planning body) as one of four extraordinary scenarios for what the world map of geopolitics will look like in the year 2020 (National Intelligence Council, 2005). ‘Mapping the global future’ with a keen attention to what the strategic planners view as the long term ‘mega-trend’ of globalization, the NIC envisions Pax Americana as a benign extension of contemporary US military dominance alongside a faltering but still extant American ability to dominate the institutions of global governance. The NIC contrasts this vision of 2020 with three others: Davos World, which is also imagined as a relatively utopian scenario, albeit with US economic authority increasingly overshadowed by rising Asian influence; The New Caliphate, a very different and distinctly dystopian vision of a world rendered unstable by what is depicted (using the imaginative geographies of orientalism) as tradition-bound Muslim resistance to globalization and American influence; and, finally, the unremittingly bleak dystopia of a so-called Cycle of Fear, in which weapons of mass destruction circulate through globalized terror networks (see terrorism), in turn envisioned as spurring an authoritarian governmental backlash of which – most fearfully of all for the NIC’s futurists – ‘globalization may be the real victim’ (NIC, 2005, p. 104).

While Pax Americana is imagined as a fairly unexceptional continuation of the current global order (relative to the three other 2020 scenarios), it is useful to consider what the alternative scenarios tell us about what has to be repressed by the NIC to continue with its exceptionalist imagining of America as a uniquely freedom-loving and anti-imperial nation-state. Cycle of Fear, for example, imagines authoritarianism and the future victimization of globalization, but all the while it obscures the already existing victims of the CIA’s own programmes of torture in Black Sites and other spaces of exception (see exception, spaces of). The New Caliphate likewise dissembles the huge role of the US intelligence agencies in helping to start, arm and even train many of the key leaders of the more violent and territorially ambitious jihadist movements in Central Asia and the Arabian Peninsula. And Davos World meanwhile betrays the still deeper contradictions that at once underlie and undermine the exceptionalist American idea that the spread of freedom and the spread of free enterprise are one and the same thing. If the rapid development of cadre capitalism in China has not made this completely clear for the NIC, then the fiasco in Iraq that has continued unabated since the publication of the 2020 report most certainly must. Here, in what was announced by many war promoters as the inaugural battle for a new and more peaceful American century, the brutality, death and destruction of a terribly unpeaceful Pax Americana has been writ large on the landscape.

Even if Pax means peace, the more important aspect of the reference to Pax Romana has always been to the violence of the ancient empire and the punitive approach that the Roman army took to subduing and incorporating the periphery into a unipolar world dominated by Rome. In 1963, President Kennedy acknowledged as much when he said that the world peace that the US sought was ‘not a Pax Americana enforced on the world by American weapons of war’ (quoted in Foster and McChesney, 2004). However, by the new millennium this return to the Roman model was exactly what the administration of President Bush was openly advocating as the rationale of the Iraq war. Given the hubris of some of the advocates of this neo-conservative foreign policy, it is not surprising that their identities often remain anonymous, but the following is reporter Ron Suskind’s (2004) account of one Bush aide’s comments:

The aide said that guys like me were ‘in what we call the reality-based community’, which he defined as people who ‘believe that solutions emerge from your judicious study of discernible reality’. I nodded and murmured something about enlightenment principles and empiricism. He cut me off. ‘That’s not the way the world really works anymore’, he continued. ‘We’re an empire now, and when we act, we create our own reality. And while you’re studying that reality – judiciously, as you will – we’ll act again, creating other new realities, which you can study too, and that’s how things will sort out. We’re history’s actors, and you, all of you, will be left to just study what we do’.

This sort of attitude clearly put the US intelligence agencies in a difficult situation – in which they had to help invent realities that helped justify the policy of attacking Iraq (Rich, 2006). The subsequent turn to scenario
building at the NIC seems to be of a piece with this story-telling-cum-war-mongering geopolitical inventiveness, albeit announced instead as a peace-loving geo-economic homage to globalization. Elsewhere, though, the turn away from reality in the name of Pax Americana has been widely criticized. With the possible exception of fans of NON-REPRESENTATIONAL THEORY, geographers have stayed put as denizens of a reality-based community that acknowledges both the limits and possibilities of SITUATED KNOWLEDGE. Thus rather than map a futuristic scenario of Pax Americana for 2020, leaders in the field have instead charted the violent destruction and dispossession that constitutes Pox Americana on the ground in the colonial present (Harvey, 2004b; Johnston, 2005d; Gregory and Pred, 2007; see also Retort, 2005). And rather than counterpose globalization and fear as opposites, critical geographers have also explored the globalization of fear that has followed from the unrelenting American pursuit of an informal and, as such, exceptionalist empire that is founded on ideas about peace and justice for all, but which is always also foundering in human geographies – from slave plantations to export-processing zones to Guantanamo – where exceptions are made in the name of the exceptionalist vision (Miller, 2006; Mitchell and Rosati, 2006; Sparke, 2005, 2007; Wright, 1999b). A brand name for this tortured concoction of capital and coercion is only fitting: Pax Americana™ – certain restrictions may apply.

peasant A term that was in common use in the English language from the fifteenth century, referring to individuals working on the land and residing in the countryside. By the nineteenth century, ‘peasant’ was employed as a term of abuse (e.g. by Marx on the idiocy of rural life), and in the recent past it has been imbued with heroic and revolutionary connotations (as in Maoism, for example). In modern usage, peasants are to be found on family farms (farming households) that function as relatively corporate units of production, consumption and reproduction (Chayanov, 1966). The particular social structural forms of the domestic unit (nuclear families, multi-generational extended families, intra-household sexual DIVISIONS OF LABOUR and property systems), the social relations between households within peasant COMMUNITIES and the ecological relations of production (the peasant ecotype) are, however, extremely heterogeneous (Wolf, 1966). The terms ‘peasant’ and ‘peasantry’ have often been employed loosely to describe a broad range of rural producers as generic types characterized by certain social, cultural or economic traits: the backward or anti-economic peasant, the rational and moral peasant, the uncaptured peasant. These and other terms such as ‘traditional’, ‘subsistence’ or ‘smallholder’ detract from the important analytical task of situating peasants as specific social producers in concrete, historically specific political economies with their own dynamics and laws of motion.

Peasants are distinguished by direct access to their means of production in land, by the predominant use of family labour and by a high degree of self-sufficiency (see SUBSISTENCE AGRICULTURE). Nonetheless, all peasants are by definition characterized by a partial engagement with markets (which tend to function with a high degree of imperfection) and are subordinate actors in larger political economies, in which they fulfil obligations to holders of political and economic power. Peasants as forms of household enterprise rooted primarily in production on the land have a distinctive LABOUR PROCESS (the unity of the domestic unit and the productive group) and a unique combination of labour and property through partial market involvement. Peasants stand between those social groups that have lost all or most of their productive assets (proletarians or semi-proletarians), on the one hand, and farming households that are fully involved in the market (so-called petty or simple commodity producers), on the other. Seen in this way, peasants have existed under a variety of economic, political and cultural circumstances (e.g. FEUDALISM, CAPITALISM and state SOCIALISM) spanning vast periods of history, and are ‘part societies’. Peasant societies are often seen as transitional – they ‘stand midway between the primitive tribe and industrial society’ (Wolf, 1966, p. vii) – and yet are marginal or outsiders, ‘subordinate to a group of controlling outsiders’ (Wolf, 1966, p. 13) who appropriate surpluses in a variety of forms (RENT, interest, unequal exchange).

In many THIRD WORLD societies in which peasants continue to constitute an important and occasional dominant stratum, a central question pertains to the fate of the peasantry in relation to growing STATE and market involvement. Peasants are invariably the victims of MODERNITY (Moore, 1966). The questions of growing commercialization and mechanization of peasant production and of the growth of off-farm income (MIGRATION, craft production, local wage labour) are reflected in the longstanding concern with internal differentiation among peasantries and hence their long-term
survival (hence the debates over peasant persistence, de-peasantization and captured peasants). It is probably safe to say that the period from 1950 to 1975 witnessed an epochal shift in which peasantry became for the first time a global minority.

The proliferation of peasant studies in the past 30 years has been the source of important theoretical innovations in political economy speaking to questions of commoditization, class formation, resistance and rebellion (Shanin, 1988). The study of peasants was also key to the evolution of cultural ecology and political ecology insofar as peasant knowledge and practice is an indispensable starting point for the understanding of household management of resources, and hence the processes of ecological change and rehabilitation (Watts, 1983a; Blaikie and Brookfield, 1987).

In the context of the transitions to and from capitalism, the role of peasantry is central. Barrington Moore (1966) argued that the relations between landlord and peasantry are fundamental in understanding the various routes of democracy and dictatorship in the modern world. Peasant revolutions in Mexico, Algeria and China, for example – the antithesis of the idea of apolitical or tradition-laden peasants – have fundamentally shaped the twentieth century (Skocpol, 1980). Kautsky (1988 [1899]) referred to the agrarian question in western Europe in the nineteenth century to underscore the political ramifications of the new forms of differentiation and proletarianization associated with growing commercialization, and the political and strategic questions that arose from peasant protest and struggle. One of the major features of the period since 1989 and the decollectivization of agriculture in the former socialist bloc has been the re-emergence of millions of peasant households (re-peasantization) in China, Russia and eastern Europe. The role of peasants in post-socialist transitions has been a crucial part of the political landscape in these parts of the world and they represent intriguing cases for the study of new forms of agrarian capitalist trajectories (see Verdeny, 1996; Selenyi, 1998). In other parts of the world, peasant entrepreneurial and political activism has also gained momentum in India (Gidwani, 2008), Indonesia (Li, 2006) and Mexico (Bobrow-Strain, 2007).

**performance** A concept that ‘is, at this moment, one of the most pervasive metaphors in the human sciences’ (Thrift, 2000a, p. 225). Its popularity has been tied to: current interest in embodiment or habits of the body; non-cognitive experiences and knowledges and the production of social life through everyday practices; and desires to de-naturalize social categories and processes, create new political opportunities and emphasize the creativity of social life. Although different approaches to performance share most of these objectives, they also differ significantly in conceptions of human agency, subjectivity and power (Gregson and Rose, 2000), and tend to direct attention to different geographies and spaces. It is common to distinguish between four approaches: a sociological dramaturgical approach, performativity (often as outlined by Butler), non-representational theory and performance studies.

The sociological, dramaturgical approach is typically traced to Erving Goffman’s ideas about the codes of conduct that govern behaviour, and the various strategies that we use to manage ourselves in the presence of others. Social life is conceived as staged by conscious agents who adhere to scripts. This is a geographical narrative that distinguishes front-of-the-stage from backstage, and public from private. Gregson and Rose (2000) argue that this has been the most prevalent notion of performance in geography. A number of studies look at the performances demanded in specific, usually service-sector, workplaces (e.g. McDowell and Court, 1994). Davidson (2003) develops the dramaturgical analogy to consider agoraphobia as a kind of ‘stage fright’ that compels those suffering from it to restrict their public performances to obviate the need to engage in ‘impression management’.

Whereas the dramaturgical analogy implies a conscious agent that exists prior to performances (Gregson and Rose, 2000), performativity outlines a process through which social subjects are produced through performances. These are ‘command’ performances, regulated by social norms, but possibilities for subversion arise from slippages between actual performances and the norms/ideals that they cite. Although Butler largely works in a temporal rather than spatial register, she points to the importance of geographical context for the meaning of any performance: ‘subversiveness is the kind of effect that resists calculation . . . the demarcation of context is . . . already a prefiguring of the result’ (1993b, p. 29). Gregson and Rose (2000) have extended the notion of performativity to space, arguing that performances do not take place in already
existing locations . . . specific performances bring these spaces into being’ (p. 441).

Non-representational styles of thought take much from performance studies, an interdisciplinary focus with closer ties to the performing arts, especially theatre and dance. It shares the emphasis on creativity and play, the intermingling of the normative and transgressive, the limits of representation, the expressive qualities of the body beyond discourse, and the full range of the senses, including the kinaesthetic (as well as attempts to develop vocabularies to document these). Performance studies places especial emphasis on liminal times and spaces that allow the temporary suspension of norms and transitory nature of an event, which can never be fully captured, preserved or repeated.

The focus on performance has opened new ways of thinking of and about research methods. The emphasis on the extra-discursive underlines the importance of witnessing in order to understand – not just how people describe their world – but how they act in their world (see ethnomethodology). Witnessing this ‘doing’ can offer opportunities to access a range of experiences and emotions that are not easily expressed through interview talk. It also prompts a different methodological approach to talk. Instead of asking respondents to describe their world, researchers have become more interested in listening to potential respondents talk while they are in their worlds. They are interested in the talk that does things. More and more researchers are experimenting with performative writing strategies, and expanding the boundaries of what counts as valuable research data and research products, to include theatre and video productions (see qualitative methods). Self-conscious research performances stretch debates about positionality and research ethics in new directions (Routledge, 2002).

Despite the convergences and overlap between different approaches to performance, there are significant disagreements that warrant further debate, especially about what counts as politics and effective political strategy. Thrift (2004c) directs us to the minutiae of performativity to harness ‘the energy of moments’ (p. 188). Houston and Pulido (2002) have criticized the individualism of much of the work within geography influenced by the concept of performance and the tendency to reduce resistance to the scale of the body. They direct us back to historical materialism and collective politics. Jacobs and Nash (2003) are also measured in their reception of non-representational theory. They argue that the emphasis on escaping categorical fixity, in an effort to accentuate processes of becoming, risks returning the unmarked (implicitly masculine) subject. They argue as well for the need to discriminate between power relations: ‘In a world in which power is understood to be radically dissimulated (as much about negotiating subjectivity or negotiating household chores, or work relations, or claiming and refusing rights), the . . . research imperative becomes one of being sensitive to the relations and proximities that matter, either in their determining forces or their transforming potential’ (pp. 274–5). How to make these determinations offers grounds for debate.

performativity One strand of the recent thinking about PERFORMANCE: it has been an important means of theorizing the workings of power in the production of rules and norms. The concept is rooted in the linguistic distinction between constative and performative utterances. A performative utterance (famously exemplified by the statement: ‘I pronounce you . . . ’, uttered at the marriage ceremony) is itself an act that performs the action to which it refers. The performative ‘brings to centre stage . . . an active, world-making use of language’ (Culler, 1997, pp. 97–8).

The concept has been worked up most thoroughly by Judith Butler in relation to GENDER and norms of heterosexuality (1990, 1993a; see queer theory). She argued that gender is a performance without ontological status: ‘There is no gender identity behind the expression of gender; that identity is performatively constituted by the very “expressions” that are said to be its results’ (1990, p. 25).
This is a more radical position than that of conventional feminist social construction, because she argues that biological sex is also produced: there is no interiorized, biological foundation on which gender rests. In this sense, gender norms are materialized by the body: they literally become matter. Butler also wrestles with a more complex subjectivity than is evident in many social constructivist accounts, because she attempts to hold psychoanalysis in tension with discourse analysis. She argues that identities are not simply performed on the surface of the body: what is performed always operates in relation to what cannot be performed or said (notably homosexual relations), mediated by the unconscious. In contrast to some accounts of social performances, those analysed as performative are not seen to be freely chosen; they are compelled and sanctioned by the norms of compulsory heterosexuality (heteronormativity), and the subject has no choice but to exist within gender norms and conventions of nature (i.e. binary sex difference). Performances are also historically embedded; they are ‘citational chains’ and their effect is dependent on conventions (i.e. previous utterances). Norms and identities are instantiated through repetitions of an ideal (e.g. the ideal of ‘woman’ or ‘man’). Since we never quite inhabit the ideal, there is room for disidentification and agency (see human agency).

Geographers have been divided in their reactions to performativity theory. Bell, Binnie, Cream and Valentine (1994) were among the first to deploy the concept, in their case to consider the subversive potential of particular performances of sexuality. Critics have been concerned that the subject of performativity is abstracted in time and place, has little agency, is conceived within a purely discursive, non-material world and is one that shares characteristics with the masculinist sovereign subject (for a review of these criticisms, see Pratt, 2004). Others have found the concept fruitful to think with: some have theorized space itself as performative (Gregson and Rose, 2000); others have drawn out the spatialities that are under-theorized in Butler’s work but necessarily underpin the process described by the concept (Thrift, 2000; Pratt, 2004). In Thrift’s words: ‘Social practices have citational force because of the spaces in which they are embedded and through which they work’ (2000, p. 677). Non-representational styles of thinking, in particular, emphasize the significance of the non-discursive and the instability of the citational process, envisioning social life ‘as processually enactive, as styles and modes of performative moving and relating rather than as sets of codified rules’ (McCormack, 2003, p. 489; original emphasis). The concept has been put to work to theorize more than gender and sexuality. Gregory (2005), for instance, brings the concept to his analysis of sovereign power; Thrift (2000) outlines a new ‘ecology’ of capitalist business practices that produce ‘fast’ managers with aptitudes for constant innovation and permanent high performance (see also cultural economy). GP

periodic market systems The regular provision of retail and other service functions at fixed points on predetermined days in the week. All of the functions may be available on certain days only: in others – as with ‘market days’ in British towns – additional functions to those available every day are provided on set days each week. There are analogies in their distribution with central place theory, as in a classic series of papers by Skinner (1964–5) on Chinese market systems. In situations with relatively low ranges and high thresholds, traders moving around markets on set days overcome problems of insufficient demand to justify permanent provision. Empirical analyses have identified a considerable range of ways in which such systems operate, however, often reflecting local cultural norms. RJ

petro-capitalism It has been said that modern life is a form of ‘hydrocarbon civilization’ (Yergin, 1991). Energy, said one critic, is ‘the precursor of economies’ (Shelley, 2005, p. 1). Oil and gas account for over two-thirds of the world’s energy supply and are indispensable to modern forms of mobility and power supply. Since the early part of the twentieth century, petroleum and industrial capitalism (and indeed industrial socialism) has been predicated on the availability of cheap petroleum. Petro-capitalism refers to two distinct but related ideas. The first is that petroleum is the fuel of modern industrial capitalism. In the context of contemporary debates over global climate change (see global warming), addiction to (or dependency on) oil as a geopolitically risky strategy for oil-importing states and the continuing debate over whether global peak oil output has been reached, there may be the beginning of a turn to other sources of energy (biofuels, nuclear and solar).
But in the short and medium term, petroleum (and gas) will continue to drive the global capitalist economy. The second meaning is that oil-producing states that depend heavily on oil revenues (as a proportion of exports or as a proportion of GDP) – what are called ‘oil-dependent economies’ in some circles (Le Billon, 2005) – are specific sorts of capitalist economy insofar as they are not simply reliant upon oil as a source of energy but are forms of rentier economy in which oil rents (royalties, taxes, sales) are the driving the entire political economy. Petro-capitalism is a particular type of extractive economy in which oil revenues, typically under state control, undergird an ambitious programme of state-led development and modernization (an exemplary case would be the Shah’s Iran in the 1970s). Nigeria, Saudi Arabia, Equatorial Guinea and Azerbaijan would be other cases of petro-capitalism – though, it needs to be said, they are customarily quite undisciplined and corrupt forms of capitalism that ‘under perform’ in relation to comparable non-oil states. Petro-capitalism in this second sense is associated with the ‘resource curse’ (Ross, 2001) (see also CONFLICT COMMODITIES).

**phallocentrism** Placing man at the centre; a masculine way of representing and approaching the world that some theorists root in male genitalia and a masculine libidinal economy; conceiving knowledge as neutral and universal, whilst refusing alternative knowledge; knowledge that represent the interests and perspectives of men. It is intertwined with logocentrism, the fixing of meaning in hierarchized binary oppositions (hence the term phallogocentrism). Phallocentrism acknowledges women, but locates their identities only in relation to men, contained within a series of binarized concepts and terms: ‘It is because sexual difference hides itself in other concepts and terms, other oppositional forms – in the distinctions between form and matter, between space and time, between mind and body, self and other, nature and culture, and so on, that it remains the latent condition of all knowledges and all social practices’ (Grosz, 2005, p. 177). Critiques of phallocentrism have led French feminists such as Hélène Cixous and Luce Irigarary, and male philosophers such as Jacques Lacan and Jacques Derrida, to explore feminine (i.e. more open and multiple) ways of writing and reading, of defining and investigating problems, including a diversity of intellectual standards for knowledge production, and diverse ways of conceiving the relations between theory and practice. Jardine (1985) terms such explorations gynesis. She regards the works of the male philosophers in particular with some suspicion, framing them as instances of male paranoia: such men began to desire to be woman as a way to avoid becoming the object of female desire.

Phallocentrism is an important concept within geography. Jardine (1985) attributes the critiques of phallocentrism (e.g. a disbelief in origins, master narratives, humanism and progress) that developed throughout the twentieth century to the end of European IMPERIALISM, as well as to the growing influence of FEMINISM. Critiques of phallocentrism have been important to the process of rethinking the concept of nature, because they are tied to attempts to displace ‘man’ from the controlling centre and to refigure nature in active, less exploitative, terms. To the extent that humanism and phallocentrism are intertwined, the critiques of that latter extend to HUMANISTIC GEOGRAPHY. Framed through the analogous concept of MASCULINISM, Rose (1993) claims that phallocentrism pervades geographical knowledge. (See also GENDER; HOMOPHOBIA AND HETEROSEXISM; SEXUALITY.)

**phenomenology** While the term ‘phenomenology’ was used in PHILOSOPHY by J.H. Lambert (1728–77), Immanuel Kant (1724–1804) and Ernst Mach (1838–1916), and is a vital part of G.W.F. Hegel’s Phenomenology of spirit (1807), in the twentieth century phenomenology began with Edmund Husserl (1859–1938) and the elaborations of his work by Martin Heidegger, Roman Ingarden, Maurice Merleau-Ponty, Jean-Paul Sartre, Max Scheler, Alfred Schütz, Jacques Derrida, Emmanuel Levinas, Alain Badiou and Giorgio Agamben, among others (see Kockelmans, 1967, pp. 24–5). For Husserl, the definition of phenomenology was straightforward: it was himself and Martin Heidegger (1889–1976).

Phenomenology entered HUMAN GEOGRAPHY in the early 1970s as a reaction to and critique of the reductive and objectivist approaches of SPATIAL SCIENCE, and of the structuralism and functionalism of some
versions of marxism then also entering the field. humanistic geography in particular turned to phenomenology to redress abstract notions of people and places. this ‘geographical phenomenology’ focused variously on everyday practices, human agency, movement, place, and social and environmental ethics (relph, 1970; tuan, 1971; butttimer, 1976; entrikin, 1976). phenomenology was seen as a philosophical and methodological approach that was attuned to human subjectivity, and its proponents read in its claim for a return to ‘the things themselves’ – an argument at once opposed to scientific abstraction and in favour of a more direct social geography of everyday lives and lifeworlds (casey, 1993).

in a major critical intervention, pickles (1985) forcefully questioned these subjectivist readings of phenomenology. pickles argued that ‘geographical phenomenology’ had overlooked husserl’s and heidegger’s critique of both objectivism and subjectivism in science as remaining in what husserl called ‘the natural attitude’. the real crisis of the european sciences was not that they treated the everyday world in overly abstract ways, but that they failed to recognize that their claims to objectivity in the natural attitude had always to be clarified and situated in terms of their constitutive regional ontologies (see ontology). werlen (1993 [1988]) subsequently elaborated such a regional ontology of everyday life and social action through a close, creative reading of the constitutive phenomenology of alfred schütz (1899–1959).

seen thus, phenomenology is not an alternative to the abstractive tendencies of science but a necessary correlate to it, seeking as it does to ground the relationship between scientific and the pre-scientific, the theoretical and the everyday, in a carefully prepared and reflective ontological analysis. phenomenology ‘does not subscribe to a “standpoint” or represent any special “direction”; for phenomenology is nothing of either sort, nor can it become so as long as it understands itself. the expression “phenomenology” signifies primarily a methodological conception. the expression does not characterize the what of the objects of philosophical research as a subject matter, but rather the how of that research. the more genuinely a methodological concept is worked out and the more comprehensively it determines the principles on which a science is to be conducted, all the more primordially is it rooted in the way we come to terms with the things themselves, and the farther is it removed from what we call “technical devices” though there are many such devices even in the theoretical disciplines (heidegger, 1927, p. 27: see methodology).

it was precisely the fact that the sciences had forgotten their own histories of concepts and approaches (cf. genealogy) that led to the need for phenomenology to clarify the regional ontologies of the sciences, knowledge production and the lifeworld. in pickles’ view, phenomenology is concerned not first and foremost with individualized, subjective geographies, but with the ways in which phenomena are constituted as intentional objects through complex historical and social processes of distanciation, thematization, abstraction and formalization (and sometimes mathematization) that constitute meaning-making in its many forms. phenomenologists are, therefore, always interested in the constitution of the specific objects, with their relational nature as objects of consciousness, intention or meaning, and with the lifeworld context that always escapes all thematization but is the precondition for any such thematization. the task of phenomenology in this sense is not to assert the priority of the everyday world over the world of science, or of place over abstract spaces, but to understand through ontological investigation how each is constituted in various historical projects of abstraction and thematization (see also gregory, 1978b).

by the 1990s and 2000s, new directions in geographical thought led to even more expanded readings of phenomenology in post-positivist geography. phenomenology was renewed by a growing interest in postmodernism and post-structuralism, particularly in ways in which anti-essentialist writings questioned what jacques derrida called phenomenology’s residual ontology: its specific commitments to particular interpretations of foundationalism, rationalism, and subject. more recently, growing interest amongst human geographers in the writings of giorgio agamben, michel de certeau, jacques derrida, michel foucault, jean-luc nancy, gayatri spivak and others has led to an appreciation of the ways in which these thinkers have adapted phenomenological thought to new ends, and the advance of non-representational theory in human geography has also been achieved in part through a reading of various forms of (post-) phenomenology.

pickles (1985).
The relationship between philosophy and geography has been a long and interesting one. To provide examples from a broadly Western tradition: Strabo argued for a close and necessary relationship between moral philosophy and geographical knowledge; Sir Isaac Newton published his own editions of Varenius’ Geographia generalis in 1672 and 1681; Immanuel Kant lectured on physical geography throughout his teaching career (1755–96); and in a 1976 interview Michel Foucault declared that geography ‘must necessarily lie at the heart of my concerns’. Each of these authors had a different view of philosophy, of course, but also of geography and geographical knowledge. For Strabo, chorography was to provide empirical particulars for reflection on truth, nobility and virtue (and also to underwrite Roman imperialism); Newton was interested in a mixed mathematical–spatial conception of geography; Kant’s lectures were descriptive, comprising a series of observations about oceans, landforms and the weather, an outline of the plant, animal and mineral ‘kingdoms’, and a survey of the ‘four parts of the world’ (Asia, Africa, Europe and America); and Foucault’s remark arose from his forensic enquiries into the relationships between power, knowledge and space.

Historians of geography had been keenly aware of this historical itinerary – at least as far as Kant – and major studies in the history of geography (see geography, history of) paid close attention to philosophical reflections on the tangled relationships between ‘culture’ and nature, notably Glacken’s landmark (1967) survey. But modern geography was slow to treat philosophy as a guide to contemporary enquiries, and interest in it was, at first, largely informal. Hartshorne’s (1939) exegesis of The nature of geography repeatedly turned to Kant to underwrite a view of concept-formation in geography as idiographic, concerned with the unique and the particular, but this was not the product of any rigorous engagement with Kant’s lectures on physical geography or their place within his work as a whole, still less with kantianism writ large. Even the repudiation of Hartshorne’s views in the 1960s was less informed by philosophy than it was driven by the desire to reconstruct geography as a spatial science: its foundations in the philosophy of science (and in particular positivism) were not codified until Harvey’s Explanation in geography (1969).

In contrast, the critique of spatial science and the formation of a series of successor projects undoubtedly depended on – and in several cases were directed by – explorations of different, avowedly post-positivist philosophies. Many of these approaches sought, like positivism or logical positivism, to identify a sort of central generating mechanism (see essentialism) and to ground their knowledge claims in a bedrock of certainty (see foundationalism). Thus the first explorations of post-positivist philosophies in human geography typically found their anchors in the human subject, language or the mind (Gale and Olsson, 1979; see also humanistic geography; phenomenology; structuralism). But these are deep waters, and at the time many geographers navigated them by treating philosophy as a ready-made ‘machine for explanation’ through which geographical cases were to be fed (Barnes, 2008a); there was little sense of a conversation between philosophy and geography. Johnston’s (1983) mapping of ‘philosophy’ on to the terrain of ‘human geography’ was typical in the privilege it accorded to philosophy, and it proved to be a template for other general surveys. Even Sayer’s (1984) influential work, one of the most philosophically astute investigations of the period, limited place and space to context and circumstance; the architectonics of explanation were derived directly from the principles of critical realism. Pickles’ (1985) careful reading of phenomenology (principally Edmund Husserl and Martin Heidegger) was almost alone in its recognition of spatiality as a crucial concern of both philosophy and human geography. Olsson’s (1980, 1991, 2007) imperturbable odyssey through philosophy (and beyond) not only had much to say to human geographers but also focused directly on some of the root-concepts in the field, especially since its reworking through spatial science: but it was conducted in such an exquisitely abstract register that many readers were probably lost en route. Part way through Olsson’s quest, the rise of postmodernism in human geography (and across the spectrum of the humanities and social sciences) did much to distract attention from the sort of modernism that informed projects like Olsson’s. Postmodernism, in concert (and often in tension) with the other ‘posts’, post-colonialism and post-structuralism, brought new writers to the attention of human geography at large. Jacques Derrida and Michel Foucault were perhaps the most prominent, later followed by Giorgio Agamben, Judith Butler, Gilles Deleuze and others. But whether any of these figures could properly be limited to the field of
‘philosophy’ is an open question, and none of them would be comfortable with the legislative function that the other humanities and social sciences so often accorded to philosophy.

In fact, appeals to philosophy as judge and arbiter were subjected to two main criticisms. The first accepted the importance of philosophical reflection, but warned against its ideological deployment:

At its best, the ‘philosophy of geography’ is that system of general ideas concerned with the direction and content of geographical work which practitioners elaborate during praxis … At its worst, the ‘philosophy of geography’ is where those who have read philosophy in general and disciples of ‘more advanced ideas in other disciplines’ exercise ideological power over those who remain with practical concerns. (Peet, 1998, pp. 8–9)

Closely connected to this complaint is Marx’s injunction, repeatedly invoked by those committed to CRITICAL HUMAN GEOGRAPHY and RADICAL GEOGRAPHY: ‘Philosophers have only interpreted the world, in various ways; the point, however, is to change it.’ That said, the development of various forms of MARXIST GEOGRAPHY was accompanied by an increasingly rigorous reading of philosophy: Louis Althusser’s ‘symptomatic’ reading of Marx’s texts had a limited audience in human geography, but Harvey’s reworking of classical Marxism and Smith’s (1984) dissection of the ligatures between CAPITALISM and UNEVEN DEVELOPMENT prompted a close engagement with a series of materialist philosophies to clarify not only questions of method but also questions of substance – see, for example, DIALECTICS, PROCESS AND PRODUCTION OF SPACE – and even a ‘symptomatic’ reading of Harvey himself (Castree, 2006a; Castree and Gregory, 2006b; Harvey, 1996).

The second objection was, in some ways, even more radical. American philosopher Richard Rorty called for the wholesale demolition of ‘Philosophy-with-a-capital-P’ and its replacement by a post-philosophical culture. He was suspicious of those who thought philosophy could provide a single, canonical language into which all questions could be translated and through whose terms all disputes could be resolved. Rorty’s PRAGMATISM acknowledged the creative capacities of DISCOURSE, and treated post-philosophical culture as a sort of ‘cultural criticism’ that claimed ‘no extra-historical, Archimedean point’ from which to offer its readings (cf. SITUATED KNOWLEDGE: see Barnes, 2008a). Rorty’s prospect did not provide a detailed model for post-foundational geographies, and nor was it intended to, but the discipline’s more recent reactivation of philosophical reflection can be read as inviting a more open and dialogical relationship between philosophy and geography. There is clearly a considerable distance between the essays on philosophy in geography collected from geographers by Gale and Olsson (1979) and the essays from both fields published in Philosophy and Geography (2001–4).

Still more significantly, however, and closely paralleling Rorty’s concerns, the renewed interest in philosophy extends far beyond philosophies of science to address political and moral philosophies. Indeed, a crucial focus of enquiry has been the entanglement of political and moral philosophies with the conduct of science: hence human geographers have effectively reactivated some of Glacken’s (1976) most vital concerns through debates about the contemporary constitution of ‘Nature’ and life itself in ways that, at the limit, invite a re-mapping of the horizons of the social and the biological (Thrift, 2008: see also BARE LIFE; BIOPOLITICS; NON-REPRESENTATIONAL THEORY). Less epically, there have been investigations of COSMOPOLITANISM and ETHICS, dwelling and PLACE, involving critical reworkings of Heidegger, Derrida and Emmanuel Levinas (e.g. Barnett, 2005; Harrison, 2007b); investigations of EXCEPTION, law and violence, involving critical reworkings of Agamben and Foucault (e.g. Gregory, 2006; Minca, 2007a); and investigations of subjectivities and spatialities, involving critical re-readings of Butler and Foucault (Pratt, 2004). This list is indicative, not exhaustive, but it points to some of the ways in which philosophy is increasingly being treated as resource rather than writ, used to inform rather than police geographical enquiry. This does not dispense with the need for close, careful and contextual reading, and collections such as Crampton and Elden’s (2007) multi-faceted readings of Foucault and geography show that the freedom to experiment with philosophical texts is not a license to ransack them.

PHYSICAL GEOGRAPHY The characterization and explanation of geological, hydrological, biological and atmospheric phenomena and their interactions at, or near the Earth’s surface. This is often, but not exclusively, in relation to human occupation and activity.
PHYSICAL GEOGRAPHY

Physical geography is something of an intellectual chimera, whose role, relations and definition have changed as the nature and focus of the geographical enterprise itself have shifted. Throughout its modern history, physical geography has been implicated in most of the central debates within geography but, arguably, prospered from none. From formal beginnings in the early Victorian age through to the period between the two world wars, a credible case can be made that physical geography was geography. Physical geographers were part of the disciplinary elite, and geographical education and research necessarily began with the physical foundations of the Earth environment, as deployed in and across natural (geographical) regions. Somewhere in the inter-war period, all this changed. Geography was recast as a subject with an essential duality of character. For the greater part of the twentieth century, debates concerning either the curse or the virtue of this duality underscored geographical reflection, while in terms of geographical endeavour, it was physical geography that repeatedly lost its place as trend-setter in the changing geographical tradition. By the later twentieth century, geography had become an amorphous and disconnected enterprise, whose concerns were less with disciplinary identity, and more with following humanistic approaches. In what became a postmodern and post-paradigmatic world, multiple and contested viewpoints were new virtues, but intellectual largesse was not bestowed on physical geography, which was represented as the manifestation of an unyieldingly, restrictive and unwelcome positivism. In the new millennium, physical geography may, however, be on the verge of renaissance. Having fought something of a quiet rearguard action within the discipline, it may yet be revived from without: first, as a new class of environmental issues demand a new kind of scientific approach; and, second, as Earth systems science – physical geography by another name and from other places – moves in to meet this need.

Earlier nineteenth-century works provided apparently firm foundations for the contemporary discipline. For example:

Physical geography is a description of the earth, the sea, and the air, with their inhabitants animal and vegetable, of the distribution of these organized beings, and the causes of their distribution. (Somerville, 1849, p. 1)

Physical geography was thus a broad, inclusive body of knowledge, embracing the work of the great natural scholars such as Alexander von Humbolt and Charles Darwin, and claiming an intellectual heritage as Immanuel Kant’s ‘propaedeutic of natural knowledge’ (Huxley, 1877). Its project was that of geography as a whole. Its scope and its holism, however, became problems as early modern science sought sophistication and institutional organization (see Livingstone, 1992), and as more and more about a wide class of natural phenomena became both known and knowable (Dickinson and Howarth, 1933). Physical geography provided an elegant underpinning of classificatory schemes:

Few sciences offer better opportunities than physical geography for studying large units and grouping their various phenomena. (Emerson, 1909, p. vii)

Its virtues were repeatedly extolled in general education, and in support of emergent environmentalism (Marsh, 1965 [1864]). It was less secure, however, as a coherent intellectual enterprise, particularly as explanation of phenomena became the goals of science. Arnold Guyot, drawing a distinction between anatomy (description) and physiology (explanation) demanded that:

Physical geography ... ought to be, not only the description of our earth, but the physical science of the globe, or the science of the ... present life of the globe in reference to their connection and their mutual dependence. (Guyot, 1850, p. 3)

Here, then, were the seeds of a basic dilemma within physical geography, which provided the backdrop for the later schism within geography as a whole. Physical geography, in search of both scientific prowess and academic distinction, had somehow either to narrow its focus (and risk trespass on established fields – particularly geology), or make ambitious claim to unoccupied territory (which, as the century progressed, could draw on post-Darwinian biology). Its response, in the shorter term, was physiography – another pervasive term with tortuous associations – and in the longer term, a dalliance with environmental determinism and its nemesis, human ecology.

In some incarnations, physiography was physical geography in all its aspects:

Physiography is a description of the substance, form, arrangement and changes of all the real things of Nature in their relation
to each other, giving prominence to comprehensive principles rather than isolated facts.  
(Mill, 1913, p. 3)

and having:

... a unique value in mental training, being at once an introduction to all the sciences and summing up of their results ... (Mill, 1913, p. 14)

In others, physiography was a more limited and scientifically precise component of physical geography, which had been:

... too often degraded into a sort of scientific curiosity shop, in which there is a vast collection of isolated facts ... without the slightest attempt ... to show how interdependent they are ... (Skertchly, 1878, p. 2)

Interdependence of natural kinds was a common theme in these early writings (see also Thornton, 1901) and recourse to the fundamental physical concepts of matter, work and energy (which seemed more at home under the label of physiography) was the common means by which this was treated. Indeed, the approach bore a striking resemblance to later attempts to rejuvenate physical geography through the applications of systems theory (see below).

Thomas Henry Huxley’s volume of 1877 was different. Huxley had ‘... borrowed the title ... which had ... been long applied ... to a department of mineralogy ...’. Significantly, Huxley’s purpose was to:

... draw a clear line of demarcation, both as to the matter and method, between it [physiography] and what is commonly understood by ‘Physical Geography.’ (Huxley, 1877, p. vi)

The grounds for this demarcation lay in the belief that physical geography had become too thoroughgoing a physical science! Huxley’s project, of course, was the extension of general elementary education, and the comments reflect his disappointment that the unique educational value of physical geography had been lost in more specialist study. Despite Huxley’s ambition to give a sense of place and purpose, where knowledge was grounded in the local and observational, his physiography was far from regional geography. Its content reflected such practicalities as how to find the North Pole or read a Times weather chart, alongside (by then) standard chapters on ice, sea, earthquakes and the sun. Notwithstanding Stoddart’s (1986) attempt to place it more centrally within geography, it probably held back, rather than promoted, the subject – albeit ahead of its time in educational terms and somewhat misunderstood. Certainly, more contemporary observers were able to label physiography as the elementary component of physical geography, and one more influenced (and limited) by concerns of relevance to human activity (Salisbury, 1907).

Later use of physiography confined it to the description of landscape, and placed it firmly within the geological tradition (Tarr, 1920). Indeed, according to Lobeck, physiography:

... should not be called physical geography, ... because the idea of the relation of life to physical environment is not within the scope of physiography. (Lobeck, 1939, p. 3)

Physiography was thus identified with geomorphology, and both terms became increasingly synonymous with physical geography. Davis (1899b) attempted to distinguish physiography from physical geography based upon a test of the presence or absence of ‘causes and consequences’ (p. iv) between environment and organic life. Physical geography made these connections; in their absence was pure landform study, or physiography as now cast. Davis rarely applied this prescription to his own work, and largely under his influence, physical geography become closely associated with regional landform description and evolution. In suggesting the test as a kind of prescription for study, he had, however, helped raise the spectre of environmental determinism, and to some, had thereby eased the passage of other areas of physical geography into a long, but ultimately blind, alley (Leighly, 1955).

Thus, while physiography allowed, as it were, greater room for manoeuvre in the jostling arena of nascent disciplines, it did nothing to clarify or confirm physical geography (or geography itself) as a coherent whole. On the one hand, physiography was a polyglot physical geography, whose project remained more ambitious than its achievements warranted. On the other, it was a specialization, related to geography around its circumference, along with the other applied sciences (Fenneman, 1919: see figure 1). So many circumferential fields of enquiry begged the question of what was at the centre. It was into this that physical geography was placed in uneasy alliance with the varying forms of regional enquiry.
For the first half of the twentieth century, physical geography informed regional geographic enquiry. At its most obvious, physical geography provided a natural definition of regions where economic and social activity appeared adjusted to, or bounded by, the natural environment. Away from the obvious physio-climatic regions, where physical geography was merely a convenient backdrop, the degree and manner in which physical geography truly engaged the human landscape was a vexing issue. Failure to answer this satisfactorily legitimized a fundamental dualism of geography, which was never successfully reconciled. Environmental determinism ran its course rather quickly, and human ecology (Barrows, 1923) became not merely its successor, but one of the defining and prescriptive terms for geography itself (Turner, 2002). Environmental determinism ran its course rather quickly, and human ecology (Barrows, 1923) became not merely its successor, but one of the defining and prescriptive terms for geography itself (Turner, 2002). While the concern was still to find something new and unique to define the subject, there was a critical twist for physical geography, insofar as:

I believe that the age-old subject of geography, though it has lost many specialities, still seeks to cover too much ground, and that it would benefit by frankly relinquishing physiography, climatology, plant ecology, and animal ecology. (Barrows, 1923, p. 13)

In this way, geography was not only reoriented but, with it, physical geography was cancelled from the geographical project (for an accessible treatment of these issues, see Unwin, 1992). Physical geography was increasingly identified as a particular form of geographical activity (most frequently manifest as applied geography) rather than as a coherent intellectual field, and at best, referred to obliquely when considering the role of human–environment relations within geography as a whole.

Not all were happy with a separation of human and physical geography, of course, and displeasure or unease came from many quarters. Hartshorne (1939), for example, was at pains to draw attention to the effective elimination of physical geography, and thereby to the restriction of geography. This was not advocacy of physical geography for its own sake, but an appeal to the heritage of Humbolt and others, which held that nature was essentially unitary. Geography’s mission was to disclose areal association, and systematic study took precedence over any particular subject matter. Dualism had arisen because of philosophical abstraction and a concern to study categories of phenomena in isolation (Hartshorne, 1959). Much the same sentiments were expressed by physical geographers such as Miller or Wooldridge, who maintained a belief in the foundational role of physical geography for regional study, even where connections were subtle or unclear:

... to hurry on content with a few shallow remarks based on perfunctory observation of the physical elements of the environment may result in overlooking or falsifying the natural intimacy of relation that nearly always exists between the physical and the cultural landscape. (Miller, 1953, p. 196)

Such convictions, although deeply situated, were rarely compellingly demonstrated, and the prevailing view of geography was one of numerous separate branches, united only in the far distant past (figure 2). Moreover, the very appeals to unity based upon identification or prescription of some essential property of geographical analysis may have contributed to the overshadowing of physical geography, both within geography and in relation to the other environmental sciences (Leighly, 1955). Leighly argued, very simply, that geographical study of any Earth surface phenomenon could be justified not for its own sake (as often misrepresented) but because its existence in place gave it legitimacy as the subject of geographical enquiry. By contrast, a physical geography that required a more complex geographical

---

**physical geography 1: The circumference of geography: ‘... each one of the specialized phases [spheres] of geography belongs equally to some other science ... In a loose way, the central part ... may represent regional geography’ (Fenneman, 1919, fig. 1, p. 4)**
justification for its material and methods hampered progress in achieving scientific engagement with the environment. This kind of physical geography (founded either in the disclosure of spatial associations or in the examination of human–environment relations – the contested identities of the subject: Turner, 2002) demanded a vocabulary and style of enquiry adapted to the scale and scope of landscape and regional study, which set it far apart from the other sciences, and which, throughout the latter half of the twentieth century, did not seem relevant to their increasingly reductionist methodologies.

As regionalism itself receded from the geographical stage, the role and relations of physical geography were once more examined. By this time, climatology, geomorphology and ecology were all well advanced separately, and without areal relations as a touchstone, there were uncomfortable parallels with the identity crisis of earlier generations:

It is clear that physical geography, however much it overlaps with the earth sciences, must be distinguished from disciplines which study terrestrial phenomena for their own sake, irrespective of their relevance to the spatial characterisation of man’s occupancy and exploitation ... (Chorley, 1971, p. 95)

For Chorley, there were several ways forward for physical geography to avoid increasing divergence within geography and to ensure ‘relevance’ to science and society beyond: common application of techniques and methods (model-building and increasingly, GIS); study of resources and development; and (general) systems theory (GST), in large part adapted from Ludwig von Bertalanffy (a biologist). Of these, only the last topic was new, and for Chorley, it was only this that provided a truly integrating concept and a widely transferable approach:

... systems can be visualised as three-dimensional structures in which the very complicated flows and relationships forming the socio-economic spatial decision-making systems interpenetrate the physical process-response systems ... (ibid., p. 22)
Chorley attempted, for a modern generation, to reconnect (physical) geography with the integrative strands of natural science, and to recapture for the subject the high ground of ambition and application (brilliantly revived in Stoddart, 1986). GST was the best way to date of representing those elusive linkages and connections (i.e. patterns and processes) that were fundamental to geography from Victorian times. The systems approach transferred readily, and enduringly, to physical geography (see Chorley and Kennedy, 1971), but appeared overly mechanistic and control-orientated (see, e.g., Bennett and Chorley, 1978), with the ascendency of humanistic perspectives. There quickly followed a time when, as Haggett (1990, p. 152) put it, consensus around a common nature of areal differentiation and common methodology evaporated as human geography was ‘Cut-off from its older geographical roots …’ and drifted towards the social sciences.

Aside from the overt concerns with disciplinary definitions and coherence, the mid-to-late twentieth century was not devoid of important substantive scholarly, as well as practical achievements by physical geographers. With hindsight, these also provided important points of attachment with contemporary scientific and environmental agendas. Barry and Chorley (1968), for example, helped to keep alive synoptic climatology as a foundational strand of physical geographical study, and their book was followed by more technically and scientifically challenging texts such as Oke’s on boundary layer climates (1978), and Henderson-Sellers’ and McGuffie’s (1989) early contribution to climatic modelling. All of these are now considered ‘classics’ and have run into multiple editions. With respect to climatic history, substantiating the character and scale of natural environmental change was arguably one of physical geography’s greatest achievements in this period. Contributions by physical geographers remain fundamental to the sub-discipline of Quaternary studies (see Goudie, 1977, and its numerous editions for review). The traditional emphasis on human–environmental interaction was also not forgotten, with physical geographers and physical geography very well represented in the landmark text, Man’s role in changing the face of the Earth (Thomas, 1956), and in its successors such as Manners and Mikeswell (1974) and Goudie (1981). (This latter volume offers a very accessible synthesis of the diverse geographical and non-geographical literature in its several newer editions.)

Another strong manifestation of physical geography in the later twentieth century occurred in environment and development studies, with the fusion of political–economic analysis and scientific–technical environmental expertise into what is now termed political ecology. Works by Blaikie (1985) and Blaikie and Brookfield (1987) are paradigmatic exemplars, and again offer enhanced valence with a much wider (geographical) literature and through the study of globalization, economics and uneven development. In the USA, for example, Butzer (2002) places concern for environment and development at the heart of a reinvigoration of physical geography that has been able to shape and enact globally significant agendas outside, as well as within academic circles. A good example of this is the CONSERVATION and ENVIRONMENTAL MOVEMENT, where physical geographers have been central in charting its origins and changing characteristics, and in defining and popularizing new directions – see, for example, the very different perspectives offered by Grove (1995), Pepper (1996) and Adams (2004).

Returning to a disciplinary theme, by the 1990s, geography inhabited a post-paradigmatic world (Abler, Marcus and Olson, 1992) and there seemed renewed possibilities to revisit older themes and once more to look for disciplinary coherence, if not unity. Indeed, physical geography was itself punctuated by a series of debates examining post-positivist EPSTEMOLOGIES (notably REALISM) and hence ONTOLOGICAL depth (Rhoads and Thorne, 1996). Both it and human geography might thus visit intellectual territory, if not with common purpose, then jointly armed with methodological and philosophical sophistication. There are, too, signs of more awareness of the role of physical geography and physical geographers in defining and progressing the discipline as a whole (Matthews and Herbert, 2004).

Outside the discipline, there are strong imperatives for the repositioning of academic approaches favourable to, if not reliant upon, physical geography. Systems approaches are being revisited across many disciplines, with a deeper theoretical perspective and the enhanced vocabulary of ‘complexity studies’ (see COMPLEXITY THEORY). Environmental debate increasingly identifies an essential linkage between science, ethics and sustainability, which necessitates both mechanistic and humanistic modes of analysis (Nordgren,
Academic subjects are reordering, with inter- and trans-disciplinarity not merely becoming fashionable but seen as prerequisites to tackle more complex environmental and societal issues (see especially the concept and consequences of hybridity – Whatmore, 2002a). In this climate, it would seem obvious that:

... widening the existing divide would be a tragic mistake that would weaken the discipline at a time when ... society needs a synthetic, coherent view of how humanity uses and abuses the physical environment ... (Abler, Marcus and Olson, 1992, p. 397)

Gregory (2005c), in perhaps the most comprehensive evaluation of the recent scope and history of physical geography, provides a welter of optimistic scenarios for its engagement to this task (see figure 3).

The recent identification of sustainability science (Kates, Clark, Corell et al., 2001) is a clear example of physical geography being used to identify and coordinate trans-disciplinary agendas that respond to large-scale, complex and hybrid environment–society–development issues. The growing ability of GIS to move from the realms of a research technology to practical application, particularly when used in tandem with a vastly increased information flow from a variety of remote platforms spanning observations of the human and biophysical world, would also seem to make the case for the renewed prospering of physical geography a compelling one. Nonetheless, there are warning signals, for while Gregory reiterates one of those critical attributes defining physical geography, whose purpose:

... is to understand how the Earth’s physical environment is the basis for and is affected by human activity. (Gregory, 2005, p. xxvii)

It is this emphasis that over a long period, has so divided and, paradoxically, often downgraded the subject outside particular ‘applied’ studies. Expectations are raised, to be disappointed in the follow-through. Crucially, the new millennium is a time when physical geography conducted on the margins of, or away from, the geographical arena is very strong. A new scientific network devoted to Earth systems science has developed, which claims the same human–environment agenda, and that may be better placed to take advantage of wider intellectual and analytical advances, and to fulfil societal needs (Pitman, 2005).

The natural claims of physical geography to privilege as an environmental discipline thus need to show an added value that transcends that derived from the collected expertise of others. It is, for example, quite possible to view physical (and environmental) geography as smaller components in a very broad, holistic science–environment framework that claims much of the same intellectual heritage and rationale as geography itself (see figure 4).

Once more, then, the hunt is on for a distinctive way forward, and for a more robust means of integrating physical geography into geography and science as a whole.

Pirenne thesis A model of the relations between international trade and urbanization in post-Roman and medieval Europe, proposed by the Belgian historian Henri Pirenne (1862–1935) (Pirenne, 1925, 2001 [1937]). The fall of the Roman Empire in AD 476 produced a politico-military crisis, but Pirenne argued that the major economic shock to the urban system came much later, from the Islamic conquest of the eastern Mediterranean and North Africa, Sicily and southern Spain (al-Andalus) in the eighth century. Long-distance Mediterranean trade was cut ‘with the elemental force of a cosmic cataclysm’, and the urban foundations of Europe crumbled as it was ‘forced to live by its own resources’. Europe fractured into a series of cellular, insular regions. It was not until the tenth and eleventh centuries, so Pirenne claimed, after the Christian Reconquista in Spain and the military campaigns of the Crusades, that
commercial recovery revived the fortunes of cities: 'Just as the trade of the west disappeared with the shutting off of its foreign markets, just so it was renewed when these markets were re-opened.' Merchants led the urban revival, spearheaded by cities in the south (especially Venice) and on the North Atlantic coast (Bruges), where they settled in grey zones close to but outside former, pre-urban fortified enclaves: the faubourg or portus.

Later work has used archaeological, numismatic and textual sources to show that the Mediterranean remained a practicable trade route throughout this period, however, though activity was concentrated in the more secure central zones, and that trade was also vigorous along the Atlantic and Baltic coasts. Still more arrestingly, McCormick (2001) argued that communications between the Frankish empire and the eastern Mediterranean surged in the final decades of the eight and ninth centuries, so that Islam did not so much 'apply the coup de grâce to a moribund late Roman system' as offer 'the wealth and markets which would fire the first rise of Europe' and its commercial economy (see also Hodges and Whitehouse, 1981). It is now also clear that towns 'of unambiguously commercial character' grew in north-west Europe from the seventh and multiplied in the eight and ninth centuries, with important implications for both geographies of local and long-distance trade and the role of merchants in shaping urban morphology (see Verhulst, 1999).

Pixel The term 'pixel' is a corrupted abbreviation of picture element – the individual elements arranged in columns and rows to form a rectangular, composite image. For example, a 1980s VGA (Video Graphics Array) monitor had a maximum resolution of 640 × 480 pixels (with 16 colours), whereas a modern Super VGA monitor can have 1,024 × 768 pixels (and 16,777,216 colours!). Raising the number of pixels per fixed area increases the resolution of an image, but also the amount of information to be processed and stored. Consequently, raster images are often compressed, as are digital photographs (as JPEGs) and DVD frames (using MPEG2).

Place In a generic sense, a place is a geographical locale of any size or configuration, comparable to equally generic meanings of area, region or location. In human geography and the humanities more generally, however, place is often attributed with greater significance (cf. landscape). It is sometimes defined as a human-wrought transformation of a part of the Earth's surface or of pre-existing, undifferentiated space. It is usually distinguished by the cultural or subjective meanings through which it is constructed and differentiated, and is understood by most human geographers to be in an incessant state of 'becoming' (Pred, 1984). Place is a central concept in human geography in general and in cultural geography in particular, but there has also been renewed interest in the concept in economic geography, where it stands for the necessity of economic processes to be grounded in specific locales and for those locales to be proactive competitors within the global economy (Massey, 1984; Harvey, 1989b). For many geographers, place and the differences between places are the very stuff of geography, the raw materials that give the discipline its warrant (cf. areal differentiation). But the potential interchangeability of place with other concepts is a sticking point.

Place, region, area and so on can denote a unit of space that has discrete boundaries, shared internal characteristics, and that changes over time and interacts with other similar units. What then makes place a distinctive concept? There are three arenas of discussion of special interest:

1) The idea that place, to be a place, necessarily has meaning. Although there are glimmers of this idea throughout the history of geography, it grew in popularity in the modern discipline with the rise of humanistic geography. Tuan (1977), Relph (1976) and a host of others approached place as a subjectively sensed and experienced phenomenon. Often taking their inspiration from phenomenology, humanistic geographers regarded place as not only the phenomenological ground for geography but also an irreducible component of human experience, without which human experience itself could not be constituted and interpreted. Such experiences included perceptions of place, senses of place and human dwelling in and memories of place (see environmental perception; memory). These were understood to be formative of the unique experiences of individuals, while also
being specific to different cultures. Places themselves were understood as unique, meaningful material constructions that reflected and articulated cultural perceptions and habits. With the rise of FEMINIST GEOGRAPHIES and a ‘new’ cultural geography in the 1980s, place was understood less through the notion of a self-adequate, intentional human SUBJECT and more through the lens of POWER-laden social relations through which human subjects were at once constituted and de-centred. That is, subjects were not understood as authors of their own intentions and meanings, but as bearers of social IDENTITIES that they did not themselves create. Place meanings came to be seen as specific to particular racial and gender-, sexual- and class-based identities (e.g. Keith and Pile, 1993; McDowell, 1997b). (This was part and parcel of the changing meanings of CULTURE in geography.) At the same time, meaning itself was cast in a new light, being viewed as much less self-evident than before. Particular attention was given to how places are represented in different cultural forms (e.g. ART, FILM, LITERATURE, MAPS), which themselves were given over to specific social uses within power-laden fields of activity (e.g. Duncan and Ley, 1993). But meaning was understood to be controlled neither by its producers nor by its consumers. Meaning had no ultimate locus: it was understood to be contestable and alterable at each point of dissemination. Another important stream of place as meaning-filled sees place as a concept that helps mark the distinction between social order/disorder, the proper/improper and so on. Place in this regard is inextricable from imposed/ internalized social and cultural rules that dictate what belongs where. It denotes the (alterable) state of belonging versus exclusion, as suggested by the expression that something or someone is ‘in place’ or ‘out of place’ (Creswell, 2004) (see also HETEROTOPIA).

(2) Place as becoming locale. Temporal change as a constituent feature of place has long been accepted, particularly in cultural-historical geographies. It is an unexceptional (yet at times politically charged) statement that places do not remain the same. Instead, place is contingently emergent. This has meant various things. It has meant that place involves transformation of some kind; for example, the transformation of a non-human element (the physical environment) by human beings into a HYBRID of culture and nature (see CULTURAL LANDSCAPE). A different kind of transformation often spoken of is the transformation from space to place. The introduction of the notion of the PRODUCTION OF SPACE has made the space and place opposition difficult to sustain, however, as it seems to render place largely as a particular moment within produced space. More recently, the emergence of place has been understood as wrought through a process of immanence. In this sense, place is not derived from something else (as place from space); it is, rather, an always-already ongoing ASSEMBLAGE of geographically associated, ONTOLOGICALLY co-constitutive elements and relationships. (Space, one might say, is fully saturated with place.) This idea of place builds upon STRUCTURATION THEORY (e.g. Pred, 1984) and, later, on NON-REPRESENTATIONAL THEORY and on the monistic thought of Gilles Deleuze and other theorists of immanence (Hetherington, 1997a; Thrift, 1999a).

(3) The de-centred, global sense of place. Recently, geographers and others have taken up the question of whether GLOBALIZATION has eliminated place as a social-spatial reality (in much the same way that globalization is claimed to have brought about the ‘death of distance’ and, still more apocalyptically, ‘the end of geography’), and whether places are degenerating into ‘NON-PLACES’ under the signs of late MODERNITY (see also PLACELESSNESS). There seems to be broad agreement that place does still matter, and that it would be wrong to see place and globalization as negating one another. For example, places/locales continue as salient features of a globalizing economy that is still marked by the production of differences through a constitutive process of UNEVEN DEVELOPMENT. Also interesting is the way in which some geographers, notably Massey (1991), have promulgated an idea of place that takes the notion of global interconnection as a precondition for place or sense of place. For Massey, place is not constituted by what is internal to it, but by its distinct lines of
connection to other parts of the world. One place is different from another on the basis of its relations to the outside. This effectively renders the distinction between ‘inside’ and ‘outside’ moot. Massey’s ‘global sense of place’ has the added virtue of a politics that looks towards the outside rather than towards a defensive localism on the basis of embattled, threatened traditions. Her sense of place nonetheless leaves open the question of whether to construe places as centres of some kind, even if only as meeting places of lines of global connectivity. Hetherington (1997), drawing upon actor-network theory, advocates somewhat differently for place as an ‘ordering process’ of diffuse but connected placings, through which a network of potentially far flung sites are enrolled into relationship with each other. (See also contrapuntal geographies.)

Cresswell (2004); Hetherington (1997a).

place-names Attaching a name to a place is a way of differentiating one place from another, but place-names are more than markers in a system of differences: they are also ways of staking some sort of claim (often of rule, domination or possession) and, as such, are frequently sites of contestation. The two spatial registers, linguistic and social, are intimately connected (cf. Pred, 1990).

In historical geography, especially in Europe, the study of place-names or toponyms is a philological discipline based principally on written evidence revealing early spellings of names. Such studies have often been used to make inferences about settlement history and landscape evolution, and have also attracted considerable controversy. Thus for Britain it was once claimed that pagan names and settlements with the element -ingas (e.g. Hastings) denoted the very earliest Anglo-Saxon settlement, while -ingham (e.g. Birmingham) represented the next stage of settlement, and the numerous instances of x’s tun names (e.g. Edgbaston: Ecgbald’s tun) marked a later establishment (Gelling, 1997). Adherents to these views also believed in the so-called ‘clean sweep’ theory, which asserts that the Anglo-Saxons were the originators of English landscapes, since a wholesale disappearance of Celtic place-names in the eastern counties denoted a land area devoid of settlers and settlements (cf. settlement continuity). Almost all of these claims have been rejected in the past 40 years. The main objection is that -ingas and -ingham place-names coincide with early Anglo Saxon archaeological remains about as little as possible, given that both occur in substantial numbers in south and east England (Dodgson, 1966). Furthermore, there are great difficulties consistently distinguishing ham meaning ‘village’ from hann meaning ‘land in a river bend’, probably dry ground in a marsh, which opens up the possibility of mistaking topographical and habitative meanings (Dodgson, 1973). However, it is recognized that if there is one nominative form more frequently associated with the early Anglo-Saxon settlers than any other it is the topographical name. It is now supposed that -tun is associated with manorialization, when society was organized in a more sophisticated manner with the establishment of the powerful institutions of kingship. A stronger continuity of Celtic populations is suggested by work charting the incidence of the word walth, which is supposed to establish the presence of substantial Welsh-speaking populations (Cameron, 1980). Studies of Scandinavian names have, however, produced greater consensus and led to some successful integrations of philological, archaeological and landscape history. These studies consistently suggest that the Danish-named villages were located in the least desirable locations from an ecological and agricultural perspective, and imply that the victorious Danes were a militarily smaller group than once claimed and did not take over or absorb pre-existing English settlements (Fellows-Jensen, 1975).

The modern world has by no means been insensitive to the histories carried in solution in place-names. Beyond Europe, and sometimes within, colonialism and imperialism exercised the power to impose new names on the landscape: naming a place coincided with the taking of place. Although the practice continues – as in Israel’s colonization and settlement of Gaza and the West Bank under its military occupation (see occupation, military: Cohen and Kliot, 1992) – subject populations do not passively adopt the new nomenclatures. Indeed, the post-colonial period has usually been marked by the recovery or invention of place-names that register a pre-colonial history and an indigenous culture (Herman, 1999; Nash, 1999). Thus, for example, Salisbury, the capital of the British colony of Rhodesia, was named after a British Prime Minister, but in 1981 it became Harare,
PLACELESSNESS

the capital of the newly independent state of Zimbabwe. Many states have attempted to fix place-names through the institution of national committees, such as the South African Geographical Names Council or the United States Board on Geographic Names (a federal institution supported by a network of committees in individual states). MODERNITY is as much an economic as it is a political project, and it is scarcely surprising that place-names have come to function not only as markers of national or cultural IDENTITY, but also as sites of commodification. A place-name, through its association with a particular regional expertise, may thus become a bearer of value for a COMMODITY (cf. INTELLECTUAL PROPERTY RIGHTS). For this reason, the European Union has attempted to regulate the attribution of regional place-names to FOOD (e.g. Roquefort cheese) and wine (e.g. Beaujolais) through a LAW on ‘protected geographical indications’: despite bilateral agreements, however, it has proved difficult to enforce these restrictions and protections outside the EU. In this sphere, as in so many others, place-names continue to mark sites of struggle in the present as they did in the past.

placelessness If by one definition PLACE represents a ‘fusion’ of human and natural worlds that become ‘significant centers of our immediate experiences’ and make it possible to live authentic, original and meaning-filled lives, then placelessness represents its antithesis (Relph, 1976, p. 141). It ‘describes both an environment without significant places and the underlying attitude which does not acknowledge significance of places’ (Relph, 1976, p. 143). Relph devised the concept as an object of critique in a treatise that became a key text in HUMANISTIC GEOGRAPHY, particularly in those versions that were inspired by PHENOMENOLOGY. Placelessness is said to result from the tyranny of ‘technique’, efficiency, interchangeability and replicability, in the design and construction of the human LANDSCAPE. It is evident everywhere from suburban houses and shopping centres to tourist attractions, restaurant chains and airports. In this sense, placelessness is a distinctly modern phenomenon that is all of a piece with the rise of mass culture, mass communication, multinational corporations and overweening central governments (see also ALIENATION; MODERNITY; POSTMODERNITY).

The concept of placelessness is not without controversy. The kinds of ‘places’ it names (suburbs, shopping strips, tourist sites and so on) have been viewed more tolerantly, even affectionately, by students of popular and vernacular culture, especially in the USA, as evinced by the writings of J.B. Jackson and his students (e.g. Jackson, 1970; Wilson and Groth, 2003). They claim an important distinction between the crass imposition of bureaucratic planning, on the one hand, and culturally original solutions to the spatial problems of everyday life, on the other. Moreover, they see in these inventive responses (not all of them ‘good’, but none so destructive as to undo place as such) a great deal of popular meaning and symbolism. More recently, geographers who study the CONSUMPTION of mass goods, including clothing, food and shelter, have argued that production does not determine consumption: thus places produced with one set of uses in mind can be claimed and hence consumed by people for quite other, often resistant, purposes (e.g. Gregson and Crewe, 2003). Placelessness has also been argued to be a necessary and important resource for the exercise of marginalized and oppressed sexual IDENTITIES, a realm of relative freedom, liberation and anonymity versus the constraints imposed by otherwise ordered places (see Knopp, 2004) (cf. HETEROTOPIA).

plantation The meaning of the term ‘plantation’ has changed over time. Originally a plot of ground with trees, it came to mean a group of settlers or their political units during British overseas expansion (e.g. the Ulster Plantation; see COLONIALISM). Later, ‘plantation’ came to mean a large farm or landed estate, especially one associated with tropical or subtropical production of ‘classical’ plantation crops such as sugar, coffee, tobacco, tea, cocoa, bananas, spices, cotton, sisal, rubber and palm oil (Thompson, 1975b: see FARMING). Most plantations combined an agricultural with an industrial process but technologies, labour processes, property rights and INFRASTRUCTURE have varied enormously across space and time, making a generic definition of plantation impossible (see AGRIBUSINESS). Plantations have witnessed historical transformations in labour relations between slave, feudal, migratory, indentured and free wage labour, and many plantations in LATIN AMERICA operated on a mixture of these labour forms (see LABOUR PROCESS; SLAVERY).
All definitions of plantation tend to differentiate it from other agricultural forms of production by size, authority structure, crop or labour force characteristics (low skills, work gangs, various forms of servility). The theory of plantations has had a long lineage that can be traced back to David Ricardo and John Stuart Mill in the nineteenth century through to H.J. Nieboer and Edgar Thompson in the twentieth. An important distinction has been made between old- and new-style plantations, in which the former (e.g. the hacienda in Central America) were essentially pre-capitalist, with surpluses directed at conspicuous consumption, while the latter were capitalist enterprises driven by the rigours of capitalist accumulation (see capitalism; feudalism; market).

Recent work has seen plantations as ‘totalizing institutions’ whose historical connections with racism and slavery have fundamentally shaped entire social and political structures (as in the Caribbean and the US South), but have also acted as powerful agents of underdevelopment (Tomich, 2004; Edelson, 2006; Pons, 2007). Plantations and plantation economies and societies cannot be understood in the terms of the narrow logic of production of the enterprise alone, however. The enormously diverse forms and circumstances in which the plantation has persisted and transformed itself must be rooted in the historical forms and rhythms of capitalist accumulation under specific land, labour and capital markets. MW

pluralism A term with more than a single distinct meaning in human geography and the social sciences:

(1) In social and cultural geography, anthropology and cultural studies, the term is invoked to describe a condition of societal diversity, usually (though not necessarily) along ethnic lines. In such uses, cultural pluralism can become synonymous with multiculturalism, and features prominently in discussions of the management of diversity – for example, the achievement of social cohesion in the states of the New Europe (Amin, 2004a). Such pluralism is usually regarded as malleable, and subject over time to the conforming forces of assimilation.

(2) More specifically, plural societies are the outcome of European colonialism in the tropics, where, according to the writings of J.S. Furnivall (1948), a distinct society emerged of indigenous and marginalized labourers, Asian merchants and European elites, and where power was commonly held in inverse proportion to group size. Furnivall’s initial work in South-East Asia was extended to the Caribbean islands by M.G. Smith, and influenced a number of studies by social geographers (Clarke, Ley and Peach, 1984). The sense of these studies is that stratification is more rigid, sustaining intergenerational divisions well into the post-colonial period.

(3) In political decision-making, ‘pluralism’ refers to a thesis associated with Robert Dahl concerning the mobility of power in modern democracies among defined interest groups. Conflicts are temporary rather than structural and may be addressed pragmatically, with elections forming the final court of arbitration. This optimistic thesis of self-governing checks and balances in the political arena has received sharp criticism, and has been superseded in the urban context in which it was first formulated by studies of growth coalitions (Jonas and Wilson, 1999) that revive the earlier elite theory that Dahl set out to undercut. DL

point pattern analysis Point pattern analysis involves looking for geographical patterns in data sets that have point \((x, y)\) geocoding given National Grid References, for example, of where a geographical phenomenon exists or takes place. A pattern is said to occur if the locations of the geographical feature or event are non-randomly distributed across a study region, meaning that they are either clustered into particular places or evenly spaced across the same.

A simple way to find patterns in point data is to plot their locations on a map. Reference is often made to the physician and epidemiologist John Snow, whose map of the distribution of deaths from the 1848 cholera epidemic in London provides an appealing allegory about how processes (the transmission of disease) create geographical patterns (a concentration of deaths around a water pump in Broad Street, Soho) which, when revealed (by mapping), suggest new information about how those patterns were caused (the discovery that cholera is a water-borne disease: see medical geography). Whilst this popular telling is part fable – the map was not actually present in Snow’s original work – the element of myth says something useful about the nature of point pattern analysis, offering an important caveat to the otherwise undoubted value of
POISSON REGRESSION MODELS

maps in supporting geographical enquiry and knowledge discovery. Shaw, Dorling and Shaw (2002) demonstrate that had Snow extended his map to include all of London, then a greater concentration of deaths would have been found south of the Thames (Soho is north of the river). Snow’s map is a RHETORICAL device – centred on a particular pump in London to illustrate his pre-existing finding that cholera is harboured by polluted water. The general problem is that maps can be created for very deliberate purposes and the eye can find (or be led to find) apparent patterns that are not necessarily validated by the data.

Point patterns are therefore verified analytically against the usual statistical benchmark by asking ‘Could we expect this by chance?’ QUADRAT ANALYSIS overlays a RASTER grid on the study region to compare the incidence rate in each cell against the average for all. Other methods of cluster detection include calculating the distance from events to either their nearest neighbour (the earliest form of pattern analysis within quantitative geography, linked to testing hypotheses derived from CENTRAL PLACE THEORY) or to other events in the study region, and also the GEOGRAPHICAL ANALYSIS MACHINE. Assessing the significance of the patterns can use probability theory or, in an era of GEOCOMPUTATION, use random redistributions of the data to simulate the effects of geography (controlling for the fact that it is hardly surprising to find more of an event in a particular part of a study region if more people live there).

As well as in EPIDEMIOLOGY, point pattern analyses are used in environmental and CRIME mapping (Chainey and Ratcliffe, 2005), supported by a range of software that include GEOGRAPHIC INFORMATION SYSTEMS, GeoDa (Anselin, Syabri and Kho, 2006) and CrimeStat (Levine, 2006). As examples of LOCAL STATISTICS, the geographical principles of these analyses can be extended to use predictor variables to help explain what is found (see, e.g., GEOGRAPHICALLY WEIGHTED REGRESSION and the GEOGRAPHICAL EXPLANATIONS MACHINE).

Poisson regression models These models belong to the family of techniques for CATEGORICAL DATA ANALYSIS. They are used when the response variable in a REGRESSION-like format is a count (e.g. the number of crimes in an area) and the researcher wants to relate this to other area characteristics. The nature of this response variable, which cannot be negative, means that the standard regression model should not be used. Instead, the natural log of the count is modelled and its random part takes on a Poisson distribution so that the stochastic variation (see STOCHASTIC PROCESS) around the underlying relationship has a variance constrained to be equal to the mean. The Poisson distribution is also used in LOG-LINEAR MODELLING for the analysis of multiway cross-tabulations. If the distribution of the count (having taken account of the predictor variables) has marked positive skew so that the variance of the residuals exceeds the mean, an overdispersed Poisson or Negative Binomial model is needed. An example of such a model is when hospital length of stay is the response; while the typical stay is a few days, some individuals may experience a stay of several months. The MULTI-LEVEL Poisson MODEL can accommodate spatial random effects.

An important use of Poisson regression is as part of a model-based approach to DISEASE mapping, as the Standardized Mortality Ratio is the ratio of observed count to an expected count. In the model, the log of the observed count is regressed on the log of the expected count and other predictor variables, with the coefficient associated with the expected count being treated as an offset, constrained to 1. Another important area of application is the calibration of SPATIAL INTERACTION models in which the response is the log of the number of FLOWS between areas. Guy (1987) shows how the Poisson model can be used to estimate quite complex models, including attraction and destination constraints.

policing At the most general level, policing refers to practices aimed at the regulation and control of a society and its members, especially with respect to matters of HEALTH, order, LAW and safety. More specifically, policing refers to the actions of those agents of the government equipped with coercive POWER to enforce law and maintain order. Amongst the key expectations of police officers is that they will work to reduce the incidence and severity of CRIME through SURVEILLANCE and arrest. Policing is thus the first stage in a criminal process that can lead to conviction and punishment.

Most research on policing in geography focuses on the legal, bureaucratic and cultural
structures that shape the geographical imaginations (see also "geographical imagination") and tactics of police officers. This work is largely ethnographic, and emphasizes the geographical routines through which the police engage their work (Fyfe, 1992) and their interest in securing territorial control (Herbert, 1997; see "territory"). This research shows that the nature of such territorial actions by officers is strongly conditioned by their prior definition of the spaces in which they are operating. For instance, police construct 'no-go areas' (Keith, 1993) or ‘anti-police areas’ (Herbert, 1997), places where histories of conflict with minorities cause officers to engage in either avoidance or heavy-handed tactics.

In recent years, police agencies have embraced geographical techniques to isolate and target specific locations of ongoing criminal activity, so-called 'hot spots'. Through reliance on geographic information systems, police departments seek to determine where crime is perpetuated and to mobilize intensive enforcement to reduce it. Evidence suggests that these tactics can be successful in reducing crime at particular places. However, such operations are expensive to conduct, and may serve merely to displace crime to other locales.

Other research on policing seeks to situate it within broader power structures of the state and state–society relations. Notable here is work on community policing, a contemporary reform movement meant to increase cooperation between officers and citizens. Observations of community policing in action demonstrate how officers retain authority in defining problems and constructing solutions (Saunders, 1999; Herbert, 2006). Research also focuses on the blurring of the lines between military and police in the growth of the 'security forces'.

Analyses of policing outside the specific context of uniformed agents of coercive state power largely occur in the context of discussions of governmentality. This refers to the processes through which individuals and groups are encouraged to assume responsibility for their own welfare and control. Such 'self-help' actions as creating defensible spaces, forming neighborhood watch groups, and employing private security represent instances where policing is presumed to extend beyond the sole province of the state. This devolution of police authority is often criticized for exacerbating class-based differences; wealthier individuals and communities can more easily protect themselves and their property, and thereby preserve their social standing.

**political ecology** An approach to, but far from a coherent theory of, the complex metabolism between nature and society (see Blaikie, 1985; Blaikie and Brookfield, 1987). The expression itself emerged in the 1970s in a variety of intellectual contexts – employed by the journalist Alex Cockburn, the anthropologist Eric Wolf and the environmental scientist Graeme Beakhurst – as a somewhat inchoate covering term for the panoply of ways in which environmental concerns were politicized in the wake of the environmentalist wave that broke in the late 1960s and early 1970s (see "environmental movement"). In its academic, and specifically geographical, usage, political ecology has a longer and more complex provenance – which both harkens back to human and cultural ecology, and to an earlier history of relations between anthropology and geography in the 1940s and 1950s, and incorporates a more recent synthetic and analytical deployment in the early 1980s associated with the work of Piers Blaikie (1985), Michael Watts (1983a, 1986), and Suzanna Hecht (1985). In the 1990s the core empirical concerns of political ecology – largely rural, agrarian and third world – were properly expanded, and the theoretical horizons have deepened the original concerns with the dynamics of resource management (see Peluso, 1992; Zimmerer, 1997; Neumann, 1999). Political ecology has also splintered into a more complex field of political ecologies, which embraces environmental history (Grove, 1995), science studies (Demeritt, 1998), actor-network theory (Braun and Castree, 1998), gender theory (Agrawal, 1998; cf. "feminist geography"); gender; gender and development); discourse analysis (Escobar, 1995) and a reinvigorated Marxism (O'Connor, 1998; Leif, 1995; cf. "marxist geography").

Two geographical monographs – *The political economy of soil erosion* (1985) by Piers Blaikie and *Land degradation and society* (1987), edited by Harold Brookfield and Piers Blaikie – provided the intellectual and theoretical foundation stones for the formalization of political ecology as such. What Blaikie achieved in *The political economy of soil erosion* was to systematize the growing confluence between three theoretical approaches: cultural ecology (Nietzschmann, 1973) in
Political ecology, rooted in ecosystems approaches to human behaviour; ecological anthropology, grounded in cybernetics and the adaptive qualities of living systems (see Rappaport, 1968); and the high tide of Marxist-inspired political economy, and peasant studies in particular, of the 1970s. A number of people contributed to this intersection of ideas – Richards’ (1985) work on peasant science, Hecht’s (1985) analysis of eastern Amazonia, Grossman (1984) on subsistence in Papua New Guinea, and Watts (1983) on the simple reproduction squeeze and drought in Nigeria – but Blaikie pulled a number of disparate themes and ideas together, drawing in large measure on his own South Asian experiences. In rejecting the colonial model of soil erosion that framed the problem around environmental constraints, mismanagement, overpopulation and market failure, Blaikie started from the resource manager, and specifically households from whom surpluses are extracted, ‘who then in turn are forced to extract “surpluses” from the environment ... [leading] to degradation’ (1985, p. 124). The analytical scaffolding was provided by a number of key middle-range concepts – marginalization, proletarianization and incorporation – that permitted geographers to see the failure of soil conservation schemes in class or social terms; namely, the power of classes affected by soil erosion in relation to state power, the class-specific perception of soil problems and solutions, and the class basis of soil erosion as a political issue. Blaikie was able to drive home the point that poverty could, in a dialectical way, cause degradation – ‘peasants destroy their own environment in attempts to delay their own destruction’ (1985, p. 29) – and that poverty had to be understood not as a thing or a condition, but as the social relations of production, which are realms of possibility and constraint.

In this work, political ecology came to mean a combination of ‘the concerns of ecology and a broadly defined political economy’ (Blaikie and Brookfield, 1987, p. 17), the latter understood as a concern with effects ‘on people, as well as on their productive activities, of on-going changes within society at local and global levels’ (1987, p. 21). This is a broad definition – an approach rather than a theory – which was adopted by the editors in the inaugural issue of the Journal of Political Ecology in 1995. Political ecology has three essential foci.

The first is interactive, contradictory and dialectical: society and land-based resources are mutually causal in such a way that poverty, via poor management, can induce environmental degradation that itself deepens poverty. Less a problem of poor management, inevitable natural decay or demographic growth (see demographic), land degradation is seen as social in origin and definition. Analytically, the centrepoint of any nature–society study must be the ‘land manager’, whose relationship to nature must be considered in a historical, political and economic context.

Second, political ecology argues for regional or spatial accounts of degradation that link, through ‘chains of explanation’, local decision-makers to spatial variations in environmental structure (stability and resilience as traits of particular ecosystems in particular). Locality studies are, thus, subsumed within multilayered analyses pitched at a variety of regional scales.

Third, land management is framed by ‘external structures’, which for Blaikie meant the role of the state and the core-periphery model.

If early political ecology was not exactly clear what political economy implied, beyond a sort of 1970s dependency theory, it did provide a number of principles and mid-range concepts. The first is a refined concept of marginality in which its political, ecological and economic aspects may be mutually reinforcing: land degradation is both a result and a cause of social marginalization. Second, pressure of production on resources is transmitted through social relations, which impose excessive demands on the environment (i.e. surplus extraction). And third, the inadequacy of environmental data of historical depth linked to a chain of explanation analysis compels a plural approach. Rather than unicausal theories one must, in short, accept ‘plural perceptions, plural definitions ... and plural rationalities’ (Blaikie and Brookfield, 1987, p. 16).

Political ecology had the advantage of seeing land management and environmental degradation (or sustainability) in terms of how political economy shapes the ability to manage resources (through forms of access and control, of exploitation), and through the lenses of cognition (one person’s accumulation is another person’s degradation). But in other respects political ecology was demonstrably weak: it often had an outdated notion of ecology and ecological dynamics (including an incomplete understanding of ecological agency: Zimmerer, 1994b); it was often remarkably silent on the politics of political ecology; it had a somewhat voluntarist notion of human...
perception; and, not least, it did not provide a theoretically derived set of concepts to explore particular environmental outcomes or transformations. These weaknesses, coupled with the almost indeterminate and open-ended nature of political ecology, not unexpectedly produced both a deepening and a proliferation of political ecologies in the 1990s (see Hecht and Cockburn, 1989; Peet and Watts, 2003 [1996]; Bryant and Bailey, 1997). A number of studies address the question of politics, focusing especially on patterns of RESISTANCE and struggles over access to and control over the environment, and how politics as policy is discursively constructed (Moore, 1996; Leach and Mearns, 1996; Pulido, 1996; Neumann, 1998; see ENVIRONMENTAL JUSTICE). Others have taken the political economy approach in somewhat differing directions: one takes the poverty–degradation connection and explores outcomes with the tools of INSTITUTIONAL ECONOMICS (Das Gupta, 1993) and entitlements, whereas another returns to Marx to derive concepts from the second contradiction of capitalism (O’Connor, 1998). Much work has addressed the original silence of political ecology on questions of GENDER (Agrawal, 1998). And still others, often drawing upon discourse theory and social studies of science, examine environmental problems and policies — often outside the THIRD WORLD — in terms of ecological MODERNIZATION, RISK and GOVERNMENTALITY (see Leach and Mearns, 1996; Braun and Castree, 1998; Keil, Bell, Penz and Fawcett, 1998; Forysth, 2003; Li, 2007).

Political ecology has in a sense almost dissolved itself over the past two decades as scholars have sought to extend its reach. At the same time, it has met up with the proliferations of forms of environmental studies, science studies, POST-STRUCTURALISM and new SOCIAL MOVEMENTS. Some of the most interesting work now speaks to the political ecology of CITIES (see URBAN NATURE), COMMODITIES and of forms of green rule and subject formation (Agrawal, 2005; Heynen, Kaika and Swyngedouw, 2006; Swyngedouw, 2004b) and violence (Peluso and Watts, 2001). Much of this work continues to struggle with the dialectical relations between nature and society that the early political ecology identified (see Harvey, 1996), however, and which continues to provide the central conundrum for what is now a hugely expanded and polyglot landscape of political ecology. political economy The study of the relationship between economic and political processes. Aristotle’s Politics distinguished between oikos, the operation of the HOUSEHOLD (on PATRIARCHAL principles) to meet daily needs, and the polis, the domain of public association and political life. In the early seventeenth century, political economy began to be used in France to discuss how economic activity might contribute to the powers of the sovereign and the prosperity of his subjects. This made economy a public rather than private activity, and located the problematic of political economy at the scale of the STATE (and implicitly as a EUROPEAN concern). Mercantilists explored how the sovereign/nation could prosper from running a trading surplus at the expense of other NATION-STATES. The physiocrats, motivated by economic crises in France, argued that the source of wealth lies in agriculture: the ‘natural’ fertility of the nation. Physiocrats began to argue that the sovereign should not govern the economy too much.

By the mid-nineteenth century, British political economy began to emerge, crystallized around the earlier ideas of Adam Smith (1723–90), flourishing into a school of thought of global influence throughout the nineteenth century. Experiencing Britain’s shift from a society founded on landowning and rural agricultural economic activities to an urban and industrial capitalist society (see INDUSTRIAL REVOLUTION), as well as the wealth brought to Britain as a result of unequal trading networks with its colonies (see COLONIALISM) and less industrialized European neighbours, it came to be argued that national wealth was embedded in labour rather than land (a LABOUR THEORY OF VALUE), and that crucial driving forces were the DIVISION OF LABOUR, the extension of the MARKET, and free domestic and international TRADE. Smith, Thomas Malthus, David Ricardo, James and J.S. Mill conceived the relationship between economic activities and the national polity in terms that aligned political economy with Lockean LIBERALISM. Freedom was founded in men (sic) owning private PROPERTY, and political intervention into their activities was an invasion of liberty and privacy. With this geographical shift from monopolical France to democratic Britain, the political came to be equated with the national state rather than the sovereign.

By the end of the nineteenth century, political economy had split into two very different,
Marxist and liberal, schools. Refining Ricardo’s labour theory of value, Marx argued that *capitalism* exploits workers, and that the crucial relationship between political and economic processes is the way in which capitalism engenders, and is shaped by, political struggle between classes (see Marxist economics). In his view, capitalism was an advance over previous modes of production, as it promoted the autonomous individual in the workplace and in political life, but sooner or later would founder on class conflicts that neither the market nor the state could finesse, giving way to a more collective, political economy founded on Communism or Socialism.

In the 1890s, partly in response to Marx’s critique of capitalism, a marginalist, subjectivist political economy emerged almost simultaneously in Britain, France, Austria, Sweden and Italy. William Stanley Jevons, Léon Walras, Carl Menger and Knut Wicksell argued that value was determined by consumers’ utility, not labour value (see Utility Theory). Using a pleasure/pain calculus, they argued that the marginal utility of everything – that is, the extra pleasure from obtaining an extra unit of a commodity – is inversely proportional to supply. In free markets, consumers would thus pay the right amount for everything purchased: its marginal utility to them. The American John Bates Clark extended the calculus to labour and capital, concluding that labour and capital will always be paid fairly in free markets, according to their marginal productivity to society. This school of neo-classical economics came to describe itself as simply ‘economics’, because in this view the economy, if left alone by the state, would maximize social welfare all by itself, harmoniously coordinating citizens’ desires. In short, the political could be evacuated in favour of the economy, to the benefit of society.

Just as liberalism has conservative and progressive variants, so does liberal political economy. Conservative, Lockean liberalism argues that freedom is the result of maintaining a minimal ‘night-watchman’ state; progressive liberalism (beginning in late-nineteenth-century Britain and migrating to the USA during the twentieth century) argues that state intervention is necessary to secure the freedom and well-being of those impoverished by capitalism. The former school, now associated with the project of neo-liberalism and its architects Milton Friedman and Friedrich von Hayek, became global common sense. It still sees itself as undertaking political economy (publishing in the Chicago school’s Journal of Political Economy), and pays close attention to political processes, but only because such processes tendentially undermine what it regards as the proper functioning of a capitalist economy. The latter school flourished in Britain and Europe during the Great Depression and until the mid-1970s, under the magisterial influence of John Maynard Keynes. As Fordism or Keynesianism, it pursued the principle of continual state intervention to manage the contradictions of capitalism to the benefit of the nation and its least well-off citizens, and saw itself as inheriting the mantle of the ‘classical’ nineteenth-century political economy of Smith, Ricardo and Marx. This rapidly fell from favour in the context of the crises of post-war Fordism and the Reagan and Thatcher revolutions, although contemporary economic commentators such as Joseph Stiglitz, Jeffrey Sachs and Paul Krugman seek to keep the flame alive.

Whereas liberal political economy dominates political science and economics, at least in the global north, political economy in geography is usually taken to mean some variant or critical elaboration on the line of thought precipitated by Marx. During the 1970s, radical geography successfully displaced liberal market-oriented approaches to economic geography, associated with location theory and spatial science, and diversified itself. In sum: versions of Marxism, from dialectical to analytical, articulate a political economy approach centred on class struggle. Realism examines how the necessary economic relations and political conflicts of capitalism are complicated by differences in geographical context. Regulation theory explores state-economy relations at various scales, comparing Fordist and post-Fordist regimes of accumulation across space and time. Approaches via governmentality argue for more attention to everyday behaviour, the conduct of conduct, rather than the state, as shaping state-civil society relations. Approaches influenced by feminism and post-structuralism draw attention to gender and identities other than class as emergent domains of inequality and conflict under capitalism. Social movements approaches theorize the emergence of social contestations of capitalism (see also resistance). The cultural turn stresses the importance of discourse and representation to the dynamics and contradictions of capitalism. Diverse and community economies approaches emphasize the ongoing importance of non-capitalist economic and
social relations, while approaches informed by POST-COLONIALISM pay attention to the geographically differentiated ongoing imprint of a colonial past, and question norms of progress and well-being associated with European capitalism (see also POST-DEVELOPMENT). If there is one thing shared across these different, at times hotly debated, critical approaches to economic geography, it is a resonance with Marx’s political economic conception of capitalism. ES

POLITICAL GEOGRAPHY

A subdivision of HUMAN GEOGRAPHY analysing ways in which politics and conflict create SPACES and PLACES and, in turn, are themselves partially determined by the existence and nature of geographical entities. The division of human geography into the broad spheres of economic, socio-cultural and political geography topics reflects the pre-eminence of disciplinary boundaries in academia. However, contemporary geography reflects criticism of disciplinary constraints and, in turn, political geography has become more eclectic and connected to other spheres of human geography. To understand the importance of this trend, a brief history of political geography is necessary.

At the outset of the development of modern human geography, political geography played a central role. Indeed, the term political geography was applied in a general sense to human aspects of geography and served as an adjunct of history. The establishment of geography as a university discipline created the initial sub-disciplines of colonial geography, COMMERCIAL GEOGRAPHY and political geography; a reflection of the discipline’s role in IMPERIALISM. The key text for the new sub-discipline was Friedrich Ratzel’s (1897) Politische geographie, which used an organic theory of the STATE to connect cultures with environments within dynamic state BORDERS. Ratzel’s influential text connected political geography to social DARWINIST ideas whereby a hierarchy of competitive cultures was defined by their differential ability to utilize the environment, with the most successful CULTURE having the right to establish a state in a particular TERRITORY. The result was the concept of LEBENSRÄUM, or living space, which would later prescribe Germany’s right to move its boundary eastwards into territory populated by Slavs.

At about the same time, Sir Halford Mackinder was both establishing political geography in universities in Great Britain and creating a political geography framework to advocate British imperialism. Also, influenced by social Darwinism and the organic theory of the state (Ó Tuathail, 1992), Mackinder is best remembered for claiming that political geography had a role in formulating grand geo-strategic plans. His ‘geographical pivot of history’ article (1904), later known as the HEARTLAND theory, defined a historical geography of European continental powers in perpetual conflict with maritime powers. In the context of Germany’s growing challenge to Britain, Mackinder saw technological change facilitating German control of Eurasia and subsequent global dominance. His solution was a strong British Empire to counter the threat. In the USA, Isaiah Bowman promoted a political geography to serve the needs of governments defining an ever-increasing role in world politics (Smith, N., 2003c).

Mackinder and Ratzel illustrate some important features of the early political geography with contemporary implications. First, they utilized grand universal theories of dubious strength to offer academic authority to state-specific foreign policy choices. Second, they connected the establishment and vitality of political geography to national SECURITY threats and the ability to offer ‘practical’ advice. Third, the analysis was state-centric, identifying states as the only important actors. Fourth, the theoreticians were socially privileged, white males, but, and fifth, they still claimed to ‘know’ the world and classify large swathes of TERRITORY as the venues for particular behaviours or characteristics. In Haraway’s (1988) phrase, they practised a ‘god’s eye-view’.

The relationship of political geography to foreign policy was epitomized by portrayals of General Karl Haushofer as the ‘evil genius’ behind Adolf Hitler’s Second World War plans for world domination (Ó Tuathail, 1996b). Greatly exaggerated by American media, the end-result was a tarnished image for political geography, as it became associated with German geopolitical expansion (cf. GEOPOLITIK). The sub-discipline withered as a research enterprise in universities on both sides of the Atlantic, ironically at the same time that the US government was expounding geopolitical theories as it achieved the status of superpower. Political geography was pushed into the academic doldrums, although it continued to be taught in many institutions, albeit with somewhat ‘dated’ textbooks and
approaches. Its focus became a functional view of the state that promoted national integration and the accumulation of capital. Two types of states were identified: independent sovereign states and dependent countries (colonies and other possessions) (Hartshorne, 1950). The latter were largely ignored as were the power relationships between rich and poor, or colonized and colonizing states. Without the previous environmental framework and with little political purpose, political geography lost its coherence and relevance (Claval, 1984). Instead, political geographers described political events (such as elections) or features (such as boundaries) in an attempt to oil the wheels of state integration and capital growth. Political geography remained state-centric, but inward-looking rather than geo-strategic, and normative rather than prescriptive.

Political geography, as with all academic studies, is a product of its social and intellectual contexts. Global competition between states and concepts of social Darwinism stimulated Mackinder and Ratzel, and post-war prosperity fuelled the blandness of functionalism. In the 1960s the global politics of the Vietnam War and internal crises manifested in race riots were linked to a growing intellectual engagement with the work of Karl Marx (see Marxism). Political geography was not immune, and over time a critical political geography began to emerge. The process was a step-by-step identification of social issues and marginalized groups, adoption of new and fertile social theoretical frameworks, and the recognition of different useful methodologies.

Initially, two broad themes were explored, both relying on spatial analytical techniques: the distribution of resources and opportunities in cities (Cox, 1973), and electoral geography (Taylor and Johnston, 1979). Both branches brought the belated introduction of analytical techniques to political geography. However, these were seen as inadequate in discovering the causes of social inequality. The parallel emergence of radical geography was seen by some as a means of identifying underlying structures that were producing social inequality and related political conflicts.

The urban problems of racial strife and economic disparity and the global problems of war and gross economic inequality provoked different uses of radical literature. David Harvey’s (1999 [1982]) Limits to Capital deployed the work of Karl Marx to explain how the production of urban spaces was a necessary and contested part of capitalism. On the other hand, Peter Taylor (1985) adopted the neo-Marxist world-systems theory of Immanuel Wallerstein to situate states within the dynamics of the capitalist world-economy. The product was a concentration on the political geography of geographical scale with the local/urban, nation-state and global scales being identified as interlinked.

Institutional support for political geography blossomed to match the changing intellectual climate. The journal Political Geography Quarterly (later Political Geography) was established in 1982. The first edition of Peter Taylor’s (1985) textbook Political geography: world-economy, nation-state and locality and a host of conferences and related edited volumes (Burnett and Taylor, 1981) identified the sub-discipline as a reinvigorated component of human geography.

However, in the 1990s human geography took what has been labelled the ‘cultural turn’ and engaged with social theorists other than Marx (see Social Theory). The result was a challenge to what was perceived as the existing reification of scale and the concentration upon economic structures. The politics of the production of scale was theorized with increasing sophistication, and feminist geographers and queer theorists (see Feminist Geographies, Queer Theory) demanded focus upon the scales of the body and the household. Political geography became increasingly eclectic as cultural geography emphasized the political conflicts inherent in cultural constructs and political geography included the cultural representation of politics. The boundaries of the sub-discipline became increasingly blurred (Painter, 1995).

One outcome was a renewed interest in the topic of geopolitics. Since the Second World War, political geography had defined itself as different from geopolitics. The topic of Critical Geopolitics (Ó Tuathail, 1996b) focused on the existing geopolitical practices of states and deconstructed the rhetoric of politicians and ‘experts’ to illuminate the underlying power politics. Critical geopolitics also promoted a concentration on non-state actors, such as social movements and indigenous groups, which also reflected calls for increased study of race, gender and sexuality (Kobayashi and Peake, 2000; Staelhi, Kofman and Peake, 2004); though these topics and theoretical perspectives are not yet fully integrated into political geographical analyses.

The concentration upon the state, nationalism and international politics, or formal
Politics, which had led the revival of political geography, was complemented by attention to the politics of representation and governance, or politics with a small ‘p’ (Flint, 2003a). The philosophies of Michel Foucault and Pierre Bourdieu, amongst others, challenged the structuralism and economism of some versions of Marxist theory, and geographers used these works to focus upon topics of governance (Hannah, 2000) and social constructions of space (Mohan and Mohan, 2002). Feminist scholars challenged the binary nature of existing theories and analyses (Staeheli, Kofman and Peake, 2004). In turn, the discipline saw an explosion of journals (Space and Polity, Geopolitics, Society and Space) as well as a surge in the publication of textbooks as political geography classes became more common in universities (Flint and Taylor, 2007 [1999]; Jones, Jones and Woods, 2004).

A coherent political geography played a key role in establishing the modern discipline of geography. However, the price of a dubious theoretical foundation was application in the name of imperialism and war. Contemporary political geography is eclectic and constantly engaging in self-critique challenging the prioritization of particular theories and social groups, and identifying key actors beyond the state. The result is a number of creative tensions. Within the sub-discipline, competing theoretical perspectives vie for attention. Also, as the ‘war on terror’ has become a dominant context (see terrorism), the issue of relevance has reappeared; producing a tension between social scientists critical of foreign policy, on the one hand, and administrators and politicians looking for geography to provide the tools and analysis to facilitate counter-terrorism.

pollution Substances released into an environment that cause harm to living organisms or built structures (e.g. roads, buildings). The substances may be human-made or natural (see environmental hazard; hazard). Harm occurs when the receiving environment cannot easily assimilate the type or quantity of substance released.

The effects of pollution range from aesthetic nuisance through to economic loss, health damage, death and long-term environmental degradation. The release of pollution may be sudden, or it may involve a slow accumulation of substances, such as the concentration of heavy metals, herbicides and pesticides in food chains. The impacts of pollution may also be gradual or sudden. The impact may be short-lived or exist for a long time. It may be local, widely dispersed or far from the source of pollution (see acid rain). Pollution may be described by its medium (e.g. air or water pollution), its character (e.g. noise pollution and acid rain) or its source (e.g. industrial pollution).

Pollution is both physical and socially constructed (see social construction). Bickerstaff and Walker (2002) demonstrate the moral geography of pollution, risk, responsibility and blame in an English city. Pollution may be regarded by some people as an ‘accident’, or understood by others as the deliberate and inevitable consequences of production processes. Sections of the environmental movement have strongly criticized production processes that generate pollution. Increasingly, efforts are being made to ‘close the circle’ by using former wastes from processes as inputs into new production processes, in what is known as ‘industrial ecology’. Regulations are enforced to prevent the deliberate emission of pollution that is considered unacceptable. Sometimes the pollutant must be treated to a standard before it is emitted. The setting of standards and their enforcement vary throughout the world because the receiving environments are different, and partly because of desires to maintain economic growth.

Concern about pollution rose dramatically after more than 4,000 people died in a photochemical smog in London in December 1952, and following the publication of Silent spring by Rachel Carson in 1962. Kates (1995) observed that the sharp decrease in pollution after the UK’s Clean Air Act of 1956 was part of a longer trend to improved air quality, resulting from the displacement of coal as a source of energy. Rachel Carson identified the dangers of a new pollutant, the insecticide DDT (Carson, 1962). It was the forerunner for concerns about many human-produced substances, ranging from pesticides through to nuclear industry waste. Continental- and global-scale pollutants such CFC emissions, acid rain and pollutants that contribute to global warming have caused most concern for governments, the environmental movement and citizens in developed countries.

Pollution is an important aspect of environmental justice in the USA (see Pastor,
population density  The number of persons divided by the area that they occupy. Within urban geography, neighbourhood and housing-based measures of density became part of discussions about urbanism, which linked context to the well-being of population groups. Within demography and population geography, density is mostly calculated at a national and regional scale, and sheds light on links between environmental conditions and population well-being (see malthus model; overpopulation). However, wide variations between countries in rates of urbanization and the availability of cultivable land undermine the use of the simple measure in a comparative sense, and have led some to favour physiological density, which divides the number of persons by the area of potentially productive land (Sambrook, Pigozzi and Thomas, 1999).

The availability of geo-referenced data and flexible models is supporting the further development of density-related classifications (Hugo, Champion and Lattes, 2003). AJB

population geography  Scholarship on the geographical organization of, and connections between, groups. Between 1953 and the 1990s, population geography defined itself as the systematic study of ‘(1) the simple description of the location of population numbers and characteristics … (2) the explanation of the spatial configuration of these numbers and characteristics … (3) the geographic analysis of population phenomena (the inter-relations among areal differences in population with those in all or certain other elements within the geographic study area)’ (Zelinsky, 1966, pp. 5–6). Accordingly, the sub-discipline thought of populations as groups synonymous with political jurisdictions (e.g. urban residents, Australians), ethnic and national identities (e.g. latino/as), phenotype (e.g. white, black), and demographic events (e.g. migrants, the elderly, families, baby boomers, refugees). As links between classifications such as these (i.e. the construction of knowledge) and the circulation of power became acknowledged, views on how populations were made and maintained, and for what purposes, have greatly expanded. This enlarged reading of groups also takes into account the relations and connections between groups, as with work that examines the meanings of whiteness in the context of blackness, or the experiences of migrancy in relation to those of sedentarism. Scholarship similarly investigates more plural views of geographical organization that go beyond the one time focus upon areal differentiation in space to recover and rework ideas about place and environment. For some, the widening agenda threatens the integrity of the vision for the sub-discipline first proposed by Trewartha in 1953; for others, growing plurality signals strength and the relevance of the field to other branches of geography and to society more generally. The recent rebranding of the flagship journal to Population, Space and Place has occurred with the rise of critical accounts (see critical human geography), and at a time of increasing ‘post-disciplinarity’ (Conway, 2004).

Contributions to population geography have long been cross-disciplinary, not least because ‘geographical’ epistemologies (particularly those related to environment, place and space) have been variously developed as part of enlightenment thinking in different disciplines, including economics, sociology and demography. Classical economic thought – most notably the malthusian model – argued that population growth rates could lead to the demand for food (resources) exceeding the capacity of the environment to supply necessary inputs. Neo-Malthusian work has expanded the concept of carrying capacity to include social and cultural factors, and use has been made of large-scale simulations and models, including the limits to growth model. Neo-Marxist critiques and views of a population–environment–resource–ideology nexus have served to complicate ideas about overpopulation and drawn greater attention to political factors (see political ecology).

While accounts concerned with environment drew attention to the links between population, scarcity and production, approaches focused upon place saw important links between population, culture and production/consumption. Reflecting the still influential ideas of the French géographie humaine school, Beaujeu-Garnier (1956–8) believed that by studying the ‘ways of being’ of
populations, the field could integrate livelihood (or environmental and economic possibilities for production) with a concern for norms, values and cultural change. This integrative account of population and nature-society links resisted the compartmentalization of population issues as separate from economic or cultural concerns, took for granted who or what constituted a population and continues to prove difficult to apply (compare Bruhnes’ 1910 treatment of settlement geography with contemporary work on global cities).

After the Second World War, population geography became institutionalized as a sub-discipline concerned with empiricist and positivist statements about spatial variations in the distribution, composition and growth of populations. The call to arms had been issued by Trewartha (1953), who saw a synthetic geography that existed for, and began with, people (populations) and their geographical organization. Trewartha made his case as spatial science gained prominence, ensuring that a view of space as a container through which the order of population phenomena could be both described and, through the development of theory, explained and modified (see location theory) permeated the field. Inspired by new data and international collaborations, and drawing on the contributions of demography in general, and demographic transition and stable population theory more specifically, population geography contributed work on the diffusion of vital transitions (notably Zelinsky’s pioneering 1971 hypothesis of the mobility transition), spatial variations in the components of population change (fertility, mortality, migration) and composition (particularly on ageing), and the development of more accurate and sub-national population projections and life table methods (Jones, 1981; Woods, 1982). Interest grew in the disaggregated behaviour of individuals with, for example, rational choice theory and social physics frameworks extended to model migration decisions at residential and regional scales (see also behavioural geography; regional science). The growth of studies in medical geography on morbidity, mortality and geographical variations in accessibility to health care combined with the relative neglect of fertility to leave commentators both bemoaning the migration-centred foci of much work and debating the need for continued disciplinary border-crossing to rejuvenate the field. While links with demography remain strong, the consolidation of fields such as spatial demography and geodemographics (Woods, 1982; Wachter, 2005) have occurred alongside, but not to the exclusion of, alternative treatments of space (White and Jackson, 1995).

The well-known critiques of Enlightenment knowledge that had taken root in human geography in the 1980s impacted upon the field in at least two ways. In methodological terms, greater emphasis was placed upon qualitative methods and ‘mixed’ methods of approaching human subjects, and taking feelings, aspirations and discourses more seriously. Life course frameworks extended life-cycle explanations of, for example, household formation, location and dissolution patterns to take account of interdependent spatial and temporal contexts, and better integrate accounts of structure and agency along structurationist lines (Van Wissen and Dykstra, 1999). The rapid development of microsimulation, agent-based modelling and geographic information science in general further exploited new data products, deepened the field’s already strong engagement with public policy and business planning, and further extended (some have argued, democratized) how population groups are defined, by whom, and for what purpose.

Indeed, the question of how knowledge about the geographical organization of populations reflects and reinforces the circulation of power in society continues to shape the direction of the field. In particular, a number of commentators have questioned the categories used in the study of populations and, most poignantly, the question of how populations are classified, named and legitimized as objects of study and policy. Post-structural views argue that populations are socially constructed institutions that both enable and counter inequality and oppression in society. Drawing on Michel Foucault, research has examined the use of political technology and discourse by states to create inferior others that legitimize political projects. Examples include the deployment of race-based classifications to underwrite ethnic cleansing and genocide, including the Nazi holocaust, and the exploitation of gender and sexuality norms against civilians and refugees in wars. Post-colonial research has investigated the link between population classifications, census and registry systems, and the mapping of ethnic populations to further colonial ends, and the neo-colonial use of discourses of migration to legitimate development agendas including structural adjustment.
programmes (Kosiński, 1984; Lawson, 2000). Drawing on FEMINIST GEOGRAPHIES and SOCIAL GEOGRAPHY, the field has re-examined the meaning of concepts of demography, including age (literatures on CHILDREN’s geographies and ageing), reproduction, DISEASE, disability, death and dying (Pratt, 1999; Valentine, 2001; Kalipeni, Craddock, Oppong and Ghosh, 2004; Silvey, 2004).

The diverse readings of space, which increasingly call upon notions of environment and place, run through the field’s expanding engagement with the economic, cultural and, to a lesser extent, ecological dimensions of GLOBALIZATION and NEO-LIBERALISM. Research on global cities explores patterns of skilled migration, the diversification of families and households, and variations in experiences of settlement, incorporation, ASSIMILATION and SOCIAL EXCLUSION among immigrant communities (Clark, 1998; Beaverstock, 2002; Wong, Yeoh and Graham, 2003). Balancing production-centred accounts of family migration, an emphasis upon gendered migration has drawn attention to factors of social reproduction and institutional context among domestic workers and persons trafficked (Boyle, Halfacree and Robinson, 1998). The growing social and spatial plurality of household living arrangements has been linked to ageing and IMMIGRATION, and has sparked new research on the demographic transition. Historically, low levels of fertility have been connected to the interplay of changes in concepts of self and a range of state policies, including housing supply and social support. Similarly, the variable ways in which states mediate TRANSNATIONAL and DIASPORIC communities, including BORDER controls, remittance management and through discourses of long-distance NATIONALISM, have witnessed a more explicitly integrative approach, combining economic, cultural and political readings (Samers, 1997; Jackson, Crang and Dwyer, 2004).

There are a number of key engagements within population geography that relate to the direction of travel and the broader influence of its scholarship. The simultaneous embrace of plurality, and the deepening methodological specialization of many approaches, ensure that time-honoured questions about intellectual coherence and vitality remain. While there is an implicit suggestion that moderation and balance (in approach, in topic and so forth) will best serve ongoing research needs and meet funding expedients, there is a tendency to define balance in terms of the long-standing demographic approach to the field. That is, migration is seen as exerting an overdue influence on research agendas, at the expense of work on fertility (and to a lesser extent mortality and composition, which are the subjects of other fields of enquiry within geography). Under post-structural and critical readings, however, this divide is artificial and problematic.

Similarly, spirited debates on methodological pluralism have supported the development of mixed methods approaches almost to the exclusion of single-method techniques, which are seen as the preserve of more specialized fields, including spatial demography. Methodological specialization has tended to exaggerate a divide between those using quantitative, qualitative and ethnographic tools at a time when many agendas require flexible and plural approaches. The growth in interest in participatory geographies represents another opportunity for reflection about the relationship between knowledge and power in the field.

Furthermore, it remains largely the case that analyses of RISK remain absent from debates within the field, despite increased public attention to matters of securitization, broadly defined (see SECURITY). Given the profound implications of well-documented ecological and cultural transitions, to name two, for the geographical organization of populations and the structure of society, work is needed to understand the roles that groups play in affecting global futures.

**Population potential** A measure of the nearness of a spatially distributed population to a point (developed as part of the MACRO-GEOGRAPHY project). The potential exerted on a point \( V_j \) is as follows:

\[
V_i = \sum_{j=1}^{k} \left( \frac{P_j}{d_{ij}} \right), \quad j \neq i,
\]

where \( P_j \) is the population at point \( j \), \( d_{ij} \) is the distance between \( i \) and \( j \) and summation is over all \( k \) points \((d_{ij} \text{ may be raised to some power, to reflect the friction of distance: cf. distance decay})\). The higher the potential at a point – \( V_j \) – the more accessible it is to the population concerned. Isopleth maps of population potential indicate the relative accessibility of a set of
points, weighted by their populations and the distances between them (as in the gravity model). Population may be replaced by another variable, such as purchasing power, to give a measure of market accessibility for each point $i$.

Stewart and Warnitz (1959); Warnitz (1965).

**population projection** A scenario about the size and composition of a population in the future (or past) that is based on a set of demographic assumptions. As 'what if' scenarios, projections should be distinguished from estimates (which aim to provide the most accurate picture of current populations) and forecasts (which aim to statistically predict the most probable scenario based on a broad range of information). The key (direct) mathematical methods for making projections include the extrapolation of demographic trends, the use of the balancing equation (see demography) and, notably, the cohort component method, which makes specific assumptions about the fertility, mortality and migration experiences of every five-year cohort in a population as it ages. The increased application of population projections in business and planning has helped fuel a virtuous circle of methodological innovation, which includes developments in sub-national projections, small-area projections, multi-region models and ethnic minority projections (Wilson and Rees, 2005).

**population pyramid** A graphical depiction of the age–sex structure of a population. This provides a visual record of the current population structure and differentiates between expanding populations (pyramid shape with concave sides), stationary populations (straight-sided) and constricting populations (beehive shape with convex sides: see the US Census Bureau for contemporary pyramids that can be animated). Pyramids also provide visual clues as to prior demographic events, including the arrival/departure of sex-selective migration streams, the impact of

![Population Pyramid](image)

1. Shortage in births due to the 1914–18 war ('empty classes')
2. Passage of 'empty classes' to age of fertility
3. Shortfall in births due to 1939–45 war
4. Baby boom
5. Non-replacement of generations

**population pyramid** France, 1897–1997 (Lévy, 1998, p. 4)
populism An enormously complex term that refers to both political ideologies and economic development strategies that are bound up with notions of the ordinary, the people, anti-industrialism and small-scale enterprise (‘small is beautiful’). Populism as practice can be seen as a counter-current, a minority discourse, to the rise of industrial capitalism. While certain lines of populist thinking can be traced to pre-industrial Leveller and Digger movements of seventeenth-century England, the intellectual origins are typically traced to Sismondi and the Ricardian socialists (Kitching, 1982).

Kitching notes that there are two senses in which populism is employed. One turns on its opposition to large-scale urban manufacture and its promotion of small-scale, moral, efficient enterprises, and the other on a particular sort of politics in which an effort is made to manufacture a national-collective will (see also hegemony; nationalism). Populist political strategies and rhetorics reside in what Laclau (1977) calls a double articulation: first, the creation of a stable bloc consisting of the people and powerful classes; and, second, the discourses by which ‘the people’s’ interests are configured with those of other classes (see class and state). Populist movements can, for example, encompass farmer radicalism, agrarian socialism, populist dictatorship (Peronism), populist democracy and urban social movements (Canovan, 1981; see also squatting). Populist, or neo-populist, development strategies can include peasant co-operatives, the informal sector, land reform and third world flexible specialization (Kitching, 1982). A powerful line of populist thinking in development geography and agrarian studies includes the work of Chayanov (see peasant).

pork barrel An American term for the unequal distribution of public goods in order to promote a political party’s or candidate’s election prospects. Pork-barrelling is usually associated with legislators obtaining benefits for the spatially defined constituencies that they represent, but the term is also used more generally to refer to any apparent government favouritism of particular areas.

positionality The fact that a researcher’s social, cultural and subject positions (and other psychological processes) affect the questions they ask; how they frame them; the theories that they are drawn to; how they read – Bondi (1999) draws a distinction between intertextual and experiential reading; their relations with those they research in the field or through interviews; interpretations they place on empirical evidence; access to data, institutions and outlets for research dissemination; and the likelihood that they will be listened to and heard. Debates about positionality have been ongoing since the 1980s, especially within feminism and feminist geographies and among those using qualitative methods. They emerge with the understanding that all knowledge is partial and from particular perspectives, embedded within power relations. In a highly influential statement, Haraway (1989) distinguished between situated knowledge and relativism, arguing that attending to positionality, as it is mediated by particular technologies for seeing (such as quantification, mapping and survey methodologies), is the route to objectivity (rather than a sign of subjectivism), and a way of making responsible knowledge claims that simultaneously chart their limits and create opportunities for developing connections across different types of knowledges.

Approaches to positionality have changed over the years, reflecting changing theories of subjectivity. In early discussions, positionality often took the form of self-critical introspection, through which researchers attempted to position themselves within power relations (often as middle-class, white and Western) in order to understand how this...
entered into their research process (see reflexivity; see also Moss, 2005). Rose (1997b) criticized these efforts to make positionality transparent. Not only is it impossible to do so, given the complexity of psychological processes, but these efforts approximate the ‘god-trick’ of complete vision criticized by Haraway. In a position that is now widely accepted, she argued that there is an irresolvable ‘unknowability’ of our own positions and those of others. From quite another direction, some have taken the position that only members of a cultural community have the right to speak for their community (England, 1994). This reflects concerns – especially among marginalized communities – that middle-class, often white, researchers reproduce existing patterns of domination through the research process and products. They often have access to information unavailable to marginalized groups, they treat the experiences of those they research as ‘raw data’ that they then interpret, they have the capacity (unavailable to marginalized groups) to present their interpretations within scholarly and sometimes policy contexts, and their research often seems to more clearly benefit them (through career advancement) than those that they study. Both the practical difficulties of identity politics and the influence of post-structural theories of the subject (see post-structuralism) have tended to soften this position. The understanding that subject positions are multiple and that social differences are constructed within relations of power has shifted focus away from binary thinking (i.e. the researcher is the same as or different from those studied) to understanding points of partial connection between researcher and researched, and how difference is constructed, including within the research process: ‘[T]he question of “Who speaks for whom?” cannot be answered upon the slippery slope of what personal attributes – what color, what gender, what sexuality – legitimate our existence, but on the basis of our history of involvement, and on the basis of understanding how difference is constructed and used as a political tool’ (Kobayashi, 1994, p. 78).

Rather than stable positionalities and relations of sameness or difference, the language has shifted to that of alliances, solidarities, collaborations, common ground and in-betweenness. Katz (1994) recommends a re-focusing of objectives, away from studying ‘those poor people’ to researching processes or sets of relations. Researchers can also re-deploy their privilege to access spaces of data collection and dissemination unavailable to the groups they collaborate with, support marginalized groups in their self-representation and multiply their communication resources (Butz and Besio, 2004). Rather than assuming that their research will benefit a needy group, a stance that Katz (1994) identifies as suspect because it elides the subjectivity of those researched, they can create situations in which all of the participants (academic, community partners and those researched) can appropriate the research products and use them in different ways to achieve their shared goals for social justice.

Besio (Besio and Butz, 2004) cautions, however, that the capacity to position oneself in this way itself depends on positionality; in some cultural circumstances, for instance, it not a simple matter for women to enter into these kinds of research collaborations. Concerns are also raised about the hazards of over-identification with particular groups and there are good arguments for the practical and analytical benefits of scholarly distance (Brown, 1995). Finally, solidarity with activist groups can raise ethical issues, posed most forcibly by Routledge (2002), when he performed a false identity in a duplicitous way to access information for activist allies. What are the ethical limits of this flexible positionality (see ethics)? This goes to the heart of what we understand as the purpose of scholarly knowledge production.

**positive discrimination** An approach that favours peoples who have traditionally suffered one or more forms of disadvantage. Positive discrimination or affirmative action programmes aim to rectify imbalances and injustices through direct intervention. In some cases, this might mean targeting policies spatially; for example, giving children from certain deprived neighbourhoods preferential access to university places. In other cases, it might involve sector targeting; for example, in the appointment of women in senior positions in industries, in which men have traditionally dominated (Berman, 1984). The aim of both is to create a more egalitarian society, reducing if not eliminating inequalities (Leach, 1974).

**Suggested reading**

**positivism** A historically variegated movement in philosophy, affirming that only
scientific knowledge is authentic knowledge, and denying validity to metaphysical (non-scientific) speculation (see also SCIENCE). The antecedents are Enlightenment thinkers such as David Hume (1711–76) and Pierre-Simon Laplace (1749–1827). But the term was first invented, and the philosophy formally codified, by the French philosopher and sociologist August Comte (1798–1851), and published in hefty instalments in his Course in positivist philosophy between 1830 and 1842 (six volumes). Subsequently, each future generation constructed positivism in accordance to its own ends, frequently minting a new title, perhaps the best known being LOGICAL POSITIVISM, born at discussions of the Vienna Circle during the 1920s (see also LOGICAL EMPIRICISM).

Six features characterize the different strains of positivism (Hacking, 1983):

1. An emphasis on the importance of observation as the foundation for all (non-mathematical) knowledge. Scientific statements were to be grounded in immediate and accessible experience of the world, through the five senses (cf. EMPIRICISM). Such immediacy guaranteed that facts were pure, untainted by theory or value judgements; they represented the world as it really was – incorrigible and inviolate. In particular, for Comte recognition of observation as the source of knowledge was the culmination of an historical process in which the errors of previous eras, characterized by the (mistaken) dominance of first religious and later metaphysical thought, were finally overcome.

2. A belief in either verification (using observations to prove a thesis), or its variant, falsification (using observations to disprove a thesis). Verification or falsification is undertaken formally, using common methods and employing rigorous techniques such as statistical inference to scrupulously determine the truth or falsity of a statement.

3. A conviction that causality seen in nature and society is nothing more than the repetitive concurrence of one event followed by another. Positivism rejects the usual interpretation of cause reckoning it obscure metaphysical baggage (who has ever observed 'a cause'?). The alternative is a formulation tethered only to experience, the constant conjunction of observable events (‘If event A, then event B': see LAW (SCIENTIFIC).

4. A suspicion of theoretical entities that by definition are non-observable. Comte said that theoretical generalizations must always be regarded at best as mere hypotheses, and logical positivists tried to reduce all theoretical statements to (legitimate) propositions of logic (an endeavour that ended disastrously). Even the less extreme solution of ‘operationalism’, that tied the meaning of a theoretical term to the empirical operations required to measure it, unravelled given the implication that each new measuring instrument defined a new theoretical term.

5. A faith in the unity of the method allowing positivism to be as efficaciously applied to the HUMANITIES and social sciences as to the physical and life sciences. This is known as NATURALISM: one method fits all, revealing Truth wherever it is found. Comte envisioned the unity as a hierarchy in which disciplines studying more complex phenomena relied on the laws discovered in disciplines concerned with less complex phenomena (Hacking, 1983), whereas logical positivists (or at least Otto Neurath) championed the Unity of Science Movement, which cast knowledge of any discipline into the single mould of physics (the monumentally conceived International encyclopaedia of unified science was to show how this was to be done, but only two volumes were ever written: Reisch, 2005).

6. The ardent denial of metaphysics (i.e. propositions bearing on the non-physical). Comte had no interest in metaphysical meaning, believing that their time literally had passed: now was the era of positivism. Logical positivists were just as extreme. A.J. Ayer (1936) titled the first chapter in his logical positivist manifesto for an English-language audience ‘The elimination of metaphysics’.

Several of these six features have been found in GEOGRAPHY since its institutionalization in the nineteenth century, although sporadically, often only tacitly and never all at once. Before the Second World War, Anglo-American geography was not much of a fit. While the discipline defined itself in terms of the meticulous recording of empirical observations, often from the field, and so met positivism’s first criterion, very few of the other criteria held, or at least for the reasons given by positivists.
For example, while geographers during this period were sceptical of theory, it was not because they were persuaded by philosophical arguments about the non-translation of an observation vocabulary into a theoretical one, but because theory implied a level of generalization that was deemed inappropriate to geographical subject matter (cf. EXCEPTIONALISM).

The advent of the QUANTITATIVE REVOLUTION in the late 1950s made positivism much more relevant to geography. Empirical observations continued to be central, although they were now often observations made by others and recorded in thick CENSUS volumes or on drums of magnetic tape (thereby shifting much geographical empirical enquiry from the field to the desk). Verification became a definitive pursuit undertaken using a set of ever more sophisticated formal statistical techniques (see QUANTITATIVE METHODS). Constant conjunctions were pursued, and Tobler (1970) announced the First Law of Geography: ‘Everything is related to everything else, but near things are more related than distant things.’ Positivism’s fourth feature, suspicion towards theoretical terms, did not apply. Geography’s quantitative revolutionaries were besotted by theory. In fact, the revolution had been primarily a theoretical one, especially in ECONOMIC GEOGRAPHY and URBAN GEOGRAPHY, which were transformed by importation of second-hand theory from physics, economics and sociology. The prospect of a unified method, however, was one of the quantitative revolution’s strongest selling points. PHYSICAL GEOGRAPHY and HUMAN GEOGRAPHY would share a common language, and geographical science would be at one rather than a house divided. Finally, quantitative revolutionaries prosecuted less the open warfare on metaphysics that positivist philosophers urged than a continual undertone of carping about the need for greater precision, less vagueness and the importance of the exclusion of value judgements (see NORMATIVE THEORY).

All of this said, there were few explicit discussions of positivism as such until it was on the way out. Morrill (1993, p. 443), one of the pioneers of the quantitative revolution, said he ‘never met a positivist’. And even Harvey’s (1969) methodological compendium for scientific geography, Explanation in geography, barely used the word (it does not appear in the index), preferring instead ‘scientific method’. The quantitative revolution was much more about getting on with the tasks of theoretical development and application, or crunching large data sets, than philosophizing about what was being done in the name of positivism. As a result, when some human geographers later vigorously attacked positivism, it did not necessarily undermine the practices of quantitative revolutionaries and spatial analysts, because the latter often neither knew nor deployed the full array of positivist tenets to begin with.

The critique of positivism was long and sustained, and in many ways still continues. Each one of the six features was criticized: (1) facts do not speak for themselves, but are always embedded in values, judgements and schemes of interpretation (see PARADIGMS); (2) truth is chimerical, and imbricated in larger social relations of POWER and knowledge (see CRITICAL THEORY; DISCOURSE); (3) constant conjunctions lead only to mindless statistical exercises, and not to explanation (see REALISM); (4) THEORY should be central to our enquiries, albeit not conceived as a mirror of the world, but as reflexive, critical, productive and provisional; (5) physical sciences offer no privileged method, but are fallible, contradictory, and limited by their historical and geographical situation (see SCIENCE); and (6) metaphysics goes all the way down, the lifeblood of our social existence and production of knowledge (see ETHICS; RELEVANCE; VALUES).

These counter-claims amount to a reassessment of the social foundations and responsibilities of intellectual enquiry, and a refusal to separate science from other discourses. Few geographers would now count themselves as positivist. Post-positivist geographies have: dimmed the enthusiasm for unbridled use of quantitative techniques; given a new slant to areas that formerly were characterized as positivist, such as economic geography and, more recently, GEOGRAPHICAL INFORMATION SYSTEMS; and opened up new fields such as FEMINISM and POST-COLONIALISM. In general, the fall of positivism in geography undermined the certainty and even optimism that the Quantitative Revolution and spatial science had promised, replacing it with what Gregory (1994) calls a ‘cartographic anxiety’ (see CARTOGRAPHIC REASON). Geography had grown up.

possibilism A claim that human societies may respond in a variety of ways to the influences of the physical environment. Possibilism
is primarily associated with the French School of human geography that had its roots in the writings of Paul Vidal de la Blache (1845–1918), but also found favour in Britain in the early-twentieth-century work of Patrick Geddes and H.J. Fleure, and in the USA in Carl Ortin Sauer’s insistence on the transformative power of human culture (see also Berkeley School). It thus stands in contrast to environmental determinism and was classically expressed in Lucien Febvre’s dictum ‘There are no necessities, but everywhere possibilities; and man, as master of the possibilities, is the judge of their use’ (Febvre, 1932, p. 27). Different philosophical roots of the doctrine have been identified, including neo-Kantian philosophy (see Kantianism: Berdoulay, 1976), probability theory associated with Poincaré (Lukermann, 1965), and Lamarckian biology (see Lamarckianism: Archer, 1993). Differences between possibilism, environmental determinism and probabilism are more easily identified when taken as ideal types rather than as operational perspectives in geographical research.

Postan thesis A major interpretation of the dynamic of the medieval economy, proposed by historian Michael Postan (1898–1981). The thesis was first developed for England, but subsequently extended to cover much of Western Europe. Postan’s ideas derived from classical political economy, particularly Ricardo and Malthus, which he saw as a framework for understanding the links between population, landed resources and living standards over the long term (Postan, 1966, 1972; Hatcher and Bailey, 2001; see Malthusian model). In so doing, he reacted negatively to linear interpretations of the medieval economy that were underwritten by a belief in the progressive growth of the market and monetization as frameworks for understanding change. Indeed, the thesis was eventually utilized as a means of understanding both European medieval and early modern pre-industrial economies (Le Roy Ladurie, 1966; Abel, 1980).

Postan accepted classical political economic assumptions about the fixity of land supply as a factor of production, minimal technological innovation in farming and diminishing returns to increased labour inputs. As a result, he viewed population growth to be unsustainable in the long term, as it led to an oversupply of labour on the land and fragmentation of land holdings. Consequently, he argued that as a result of population growth over the thirteenth century, associated with real wage falls and shrinkage of holding sizes, an increasingly harvest-sensitive population emerged that was vulnerable to periodic crises (Postan and Titow, 1958–9). These were observable in a consistent tendency for death rates to rise with grain prices and responsible for cataclysmic phases such as the Great European famine of 1315–22. Furthermore, he was inclined to see susceptibility to high death rates associated with epidemic disease such as the Black Death as a manifestation of society’s vulnerability resulting from an imbalance between population and resource available per capita. Postan added other elements to this interpretation, such as a belief in the decline of soil fertility that arose as populations cropped land too frequently and nitrogen levels plummeted, driving communities to cultivate soil types that were inherently unsuitable for arable farming and grain production. He believed that population decline in the fourteenth century was a punishment for ‘overfishing’ in the previous century, and that the damage done to soil fertility was not repaired until at least the sixteenth century when population totals began again to recover.

Since Postan’s death, historians and historical geographers have contested the idea that technology was unchanging and argued that the thirteenth- and early fourteenth-century economy was showing signs of developing specialization and genuine comparative advantages in a manner more consistent with Smithian growth theory (Britnell, 1993; Britnell and Campbell, 1995). It has also been argued, in conformity with the Boserup thesis, that in densely populated areas of England grain yields were increased by an increase in labour inputs as land was cropped, weeded and fertilised more frequently (Campbell, 1983, 2000). Others have sought alternative explanations for weakness in the economy associated with seigneurial exploitation through the removal of surpluses legitimised by serfdom as a relation of production (see Brenner thesis). More recently, it has been claimed that the difficulties associated with harvest failure were in many instances caused by extreme natural events that would have impacted adversely on any pre-industrial economy (Bailey, 1992). It has also been argued that exogenously generated epidemic disease that brought down population
levels after 1347 had little to do with the living standards of the population since rich and poor were equally susceptible (Bailey, 1996). Nonetheless, the model remains a powerful statement to which many interpreters still adhere on account of its conceptual elegance.

Post-colonialism An intellectual movement originating in literary and cultural studies concerned with the diverse, uneven and contested impact of colonialism on the cultures of colonizing and colonized peoples, in terms of the way in which relations, practices and representations are reproduced or transformed between past and present, as well as between the ‘heart’ and the ‘margins’ of empire and its aftermath. While the proliferation of uses and implied meanings of the term ‘post-colonial’ (and its conflation with other terms such as ‘neo-colonial’, ‘ex-colonial’, ‘anti-colonial’, ‘post-independence’ and ‘post-imperial’) has resulted in a tangled skein of intellectual threads, post-colonialism as a form of ‘critical analysis of colonialism and its successor projects’ takes as axiomatic the following: (1) a ‘close and critical reading of colonial discourse’; (2) an understanding of ‘the complicated and fractured histories through which colonialism passes from the past into the present’; (3) a mapping of ‘the ways in which metropolitan and colonial societies are drawn together in webs of affinity, influence and dependence’; and (4) a sensitivity to the ‘political implications’ of the way history is constructed (Gregory, 2000).

Post-colonialism may refer to something tangible, with ‘real political and historical references in space and time, locating cultural as well as economic and political connections between metropole and colony’ (King, 1993, p. 90). This take on post-colonialism can be distinguished in work focusing on forms of post-colonial expressions and identity such as the social, demographic, political, cultural and spatial forms, styles and identities in once-colonial societies of the periphery (Simon, 1998, p. 230). Post-colonial nation-states are often ‘overwhelmed with the onslaught of representational spaces’ in attempts to produce the ‘ideal of the post-colonial citizen’ (Srivastava, 1996, p. 406). Urban forms and architecture, in particular, have been treated as ‘a social and political means of representation in which a post-colonial nation forms a dialogue with its colonial past’ (Kusno, 1998, p. 551). Post-colonial strivings for a new identity do not completely banish the colonial past, but involve the selective retrieval and appropriation of indigenous (see indigenous knowledge) and colonial cultures to produce appropriate forms to represent the post-colonial present. Often ‘ironic’, ‘contradictory’ and anxious about ‘inauthenticity’, post-colonial identity is constituted by both a ‘relatively unproblematic identification with the colonizer’s culture, and a rejection of the colonizer’s culture’ (Kusno, 1998, p. 550).

Using the term ‘post-colonialism’ to refer to a specific period after colonialism is, however, problematic, as the historical reality in the second half of the twentieth century in the once-colonized world was shaped by ‘a modernity that is scored by the claws of colonialism, left full of contradictions, of half-finished processes, of confusions, of hybridity, and liminalities’ (Lee and Lam, 1998, p. 968).

Post-colonialism must be understood in a plural sense, for there are ‘quite radical differences in the “colonial” relationship between the imperial centre and the colonized in the various parts of the former empires’ (Mishra and Hodge, 1991, p. 412). The term is hence less usefully tied to a specific historical moment, a political status or a concrete object. Instead, more critically, the ‘post-colonial’ is used to signify ‘an attitude of critical engagement with colonialism’s after-effects and its constructions of knowledge’ (Radcliffe, 1997, p. 1331). It provides a conceptual frame that works to destabilize dominant discourses in the metropolitan West, to challenge inherent assumptions, and to critique the material and discursive legacies of colonialism (Crush, 1994; Jackson and Jacobs, 1996; Jacobs, 1996, Blunt and McEwan, 2002; McEwan, 2003). Post-colonial critique engages with ‘the monumental binary constructions of East/West, traditional/modern, natural/cultural, structural/ornamental’ in order to locate ‘productive tensions arising from incommensurate differences rather than deceptive reconciliations’ (Nalbantoglu and Wong, 1997, p. 8).

The emancipatory radicalism and recuperative stance ascribed to the ‘post-colonial’ have been questioned in a number of ways. Critics argue that just as the application of the category ‘pre-colonial’ to societies prior to their incorporation into European political and economic systems tend to fix the ‘colonial’ as the main point of reference, adding the prefix ‘post-’ may also impose ‘the continuity of
foreign histories’ and ‘subordinate indigenous histories’ (Perera, 1998, p. 6). It begs the question whether the condition of the world today has been so reconfigured as to be ‘incontrovertibly post-colonial’ (Hall, 1996, p. 256), or whether it is more likely that ‘colonialism left the everyday life of many quite untouched; or that the changes it did bring often passed unrecognized as changes’ (During, 1992, p. 346). Privileging ‘the moment of the “post-colonial”’ … [may] simply revive or re-stage exactly what the post-colonial so triumphantly declares to be “over”’ (Hall, 1996b, p. 248; cf. Gregory, 2004).

Others have cautioned against the navel-gazing tendencies of certain forms of post-colonial studies – which seem reluctant to go much further beyond theorizing ‘the meaning of the hyphen’ (Mishra and Hodge, 1991, p. 399) – and have emphasized instead the need for post-colonial studies to engage with ‘material practices, actual spaces and real politics’ (Sylvester, 1999, p. 712: see also Driver, 1996; Jackson and Jacobs, 1996; Barnett, 1997, p. 137; Lester, 1998; Driver and Gilbert, 1999b).

If the main limits of post-colonial theories lie in their mistaken ‘attempt to transcend in Rhetoric what has not been transcended in substance’ (Ryan, 1994, p. 82), then an important starting place in overcoming some of these limitations would be to dissect post-colonialism as threaded through real spaces, built forms and the material substance of everyday biospheres.

At the same time, the ‘prospects of getting past the post’ (Yeoh, 2001) must be tied to the larger enterprise of constructing and elaborating alternative post-colonial geographical traditions that will steer a path through what Ram (1998, p. 628) calls ‘on the one hand, a sphere of the modern which is so hopelessly contaminated by its colonial origins that it seems exhausted as a source of critique and action, and on the other, a non-elite discourse which is completely unconnected with the modern and is unable to represent anything other than utter OTHERNESS’. The first steps are the most difficult, as Chatterjee (1994, p. 216) points out: ‘EUROPE and the AMERICAS, the only true subjects of history, have thought out on our behalf not only the script of colonial enlightenment and exploitation, but also our anti-colonial resistance and post-colonial misery.’ Sidaway (2000, p. 593) also notes that ‘any postcolonial geography must realize within itself its own impossibility, given that geography is inescapably marked (both philosophically and institutionally) by its location and development as a western-colonial science’. For a post-colonial geography to aspire to significant breaks with the prescribed script, one step forward would be to view post-colonialism as a highly mobile, contestatory and still-developing arena, where opportunities for insight may be gained at multiple sites. While its redemptive features as a means of resisting colonialisms of all forms and its manipulative aspects as a vehicle for colonialism to reproduce itself cannot be totally disentangled, its critical edges may be sharpened not only to ‘dismantle colonialism’s signifying system’, but also to articulate the silences of the native by ‘liberating the suppressed in discourse’, and to speak back to the centre (Alatas, 1995, p. 131: see also Rattansi, 1997; Nagar and Ali, 2003). In this vein, Robinson (2003a, citing Chakrabarty) calls for a ‘provincialising’ of Western scholarship, followed by a more sustained engagement with cosmopolitan practices in the production of post-colonial knowledge.

**post-development** A tradition of thinking and political action that refuses to accept that DEVELOPMENT is somehow natural or innocent. Its proponents also dispute the suggestion that ‘developing countries’ can or should follow in the footsteps of the west/north. Some post-developmentalists go further and argue that the DISCOURSE of development has done immense damage in the global South. Arturo Escobar (1995) has famously maintained that development produced only FAMINE, debt and increased POVERTY for the majority world. Post-1950 development had failed, he said, and other modes of being had to be discovered and worked through. In this vein, post-development refers to that set of ecological, economic and cultural experiments that will produce new and presumably better ways of being human.

Post-development thought is really a spectrum of oppositional thinking that mixes old and new insights in roughly equal measure. At one end of the spectrum is a tradition of ANTI-DEVELOPMENT thought that is frankly dismissive of development. Anti-development activists reach back to Mahatma Gandhi and Leo Tolstoy when they contend that development is violent and dehumanizing. There is more than a hint of this thinking in Escobar’s book, *Encountering development: development*...
has failed and it must be overcome. But Escobar also draws on work produced by Dependency theorists in the 1960s, including André Gunder Frank. Like many others, he maintains that the dominant model of economic Modernization in the North cannot be exported to the global South. The core countries use their power to prevent balanced development. It would also be unwise, and probably impossible, for the majority world to copy the ecologically exploitative model of development pursued in the North (see also Core–Periphery model).

What made Escobar’s work so challenging, however, was the fact that he drew on work by Michel Foucault and the subaltern studies collective to think about the production of development as a form of governmentality. Escobar argued that the Third World had been invented by American aid programmes as the residual in a Cold War struggle between the First and Second Worlds. There is nothing natural about this social construction—nothing, save for an uncommon history of colonialism—that produced this diverse mix of countries as a singular space that henceforth would be defined by its ‘mass poverty’ and pathological lack of development. Escobar, in other words, argued that an imagined geography of underdevelopment was constructed by a discourse of development that infantilized the majority world in relation to a mythical view of a perfect and benevolent West. Under the sign of development, Western experts (aid workers, technicians, military personnel) were then set free in the Third World ostensibly to secure its own dissolution. The fact that the United Nations designated the 1960s as the Development Decade speaks to the hubris that Escobar is so keen to skewer.

Escobar’s work has been important in forcing a re-evaluation of the (un)productive work performed by developmentalism. By linking the study of development to geopolitics, Escobar was able to raise important questions about the meanings of colonialism. Was development not simply the continuation of colonialism by another name? Did it not turn Third World men and women into a set of experimental subjects, to be dissected later in a museum or university? (See Ashis Nandy’s comments on the back cover of Encountering development.) At the same time, there are weaknesses in Escobar’s account. His suggestion that development began in 1949 ignores a history of thinking about progress and disorder (about development) that has been explored in some detail by Arndt (1981) and Cowen and Shenton (1996). Corbridge (1998) and Kiely (1999) have further argued that Escobar’s insistence on a singular discourse of development blinds him to the different governmental interventions that emerge from, for instance, the basic needs agenda, a Gender and Development framework or neoliberalism. At times, Escobar comes close to the anti-development position of wanting to escape from all forms of governmentality. But it is not clear how this escape will be effected; nor is it clear that Escobar has spelled out the opportunity costs of his development alternatives. In part, this is because he damns development in its entirety, failing to note that life expectancies in many parts of the world increased at a historically unprecedented rate after 1950.

If Escobar uses Foucault to moralize about developmentalism, other versions of post-development thinking are less obviously normative. Partha Chatterjee (2004), for example, has begun to develop a post-colonial response to what he calls the ‘unscrupulously charitable’ gestures of neoliberalism, and of the new public administration (NPA) that so often goes with it. He has repeatedly drawn attention to the different chronologies of the creation of the modern state in the West and in the countries of Asia and Africa. In his view, technologies of governmentality and the creation of named populations pre-date the formation of the nation-state and civil society in most of the world. NPA demands for good governance and participatory development by individuals are often wildly at odds with local realities, where people need the support of skilled brokers in political society. In an exploration of development and bureaucratization in Lesotho, James Ferguson (1990) has charged that, while individual development projects fail on a regular basis, they combine to produce an anti-politics machine that substitutes the technical jargon of development for concerted public discussion of gender relations, land rights, the nature of the state and so on. Ferguson’s argument, in other words, is not that development has failed (pace Escobar). Rather, it is that a reasonably diverse range of development interventions has failed to end rural poverty in Lesotho, but has succeeded, sometimes unwittingly, in extending bureaucratic state power in the countryside.

Ferguson’s work on the anti-politics machine suggests one fruitful avenue for a post-developmentalism that maintains links to radical development thinking. Similar
accounts of the depoliticization of development have been essayed by Peter Uvin (1998) on aid agencies in Rwanda, John Harriss (2001) on the banalities of Robert Putnam’s work on social capital theories and David Mosse (2005) on the power effects of a major UK aid project in India. It is here perhaps, and in explorations of the ways in which development thinking continues to express Western anxieties or fantasies about ‘itself’ (Gilman, 2003), that post-development thought has most to offer.

Post-Fordism
A set of production techniques that are more flexible than those associated with fordism and are used as part of flexible accumulation. The techniques have three main characteristics: (1) flexibility is emphasized both in the skills of workers (who may be part-time to allow their flexible deployment as and when there is demand for a product) and in the functionality of machines that need to be reprogrammable and useable for producing a variety of different products; (2) vertical disintegration rather than vertical integration, as production relies on a close-knit network of suppliers who can quickly respond to changes in demand; and (3) an emphasis on accurate and high-quality final products because of the just-in-time production and the selectivity of consumers. Post-Fordism is often said to have emerged in response to the crisis conditions of the 1970s, when Fordism as a mode of production and regime of accumulation became unstable. However, others have pointed out that in reality many of the techniques associated with post-Fordism have existed since before the emergence of Fordism itself and were simply reinvented in the early 1980s (Gertler, 1988; Amin, 1994). Indeed, the term ‘after-Fordism’ was used by Peck and Tickell (1994) in recognition of the lack of a coherent set of principles underlying post-Fordism and the way in which elements of both Fordism and flexible accumulation often coexist in the production techniques and strategies of firms.

For geographers, post-Fordism is inextricably linked with the region or cluster, because of the importance of agglomeration and localization economies for flexible production. JF

Posthumanism
An intellectual and cultural style of work, evident in critical theory, architecture, philosophy and the social sciences, that emphasizes the impurities involved in becoming human, oriented against a humanist tradition that has long been the dominant mode of understanding in the humanities and social sciences. Where humanism supposes that humans, with their capacities for rationality, consciousness, ingenuity, soul, language and so on, stand at the centre of social action and can transcend the natural realm, posthuman work insists that all of these capacities are achieved with the help of many others (including non-humans). Two related bodies of theoretical understanding are often used to make such claims (Braun, 2004a). The first draws upon new forms of vitalism (Watson, 1998), associated with readings of Henri Bergson and Gilles Deleuze, where matters as elusive as consciousness, mind, memory and other repositories often labelled quintessentially human, are taken to be nothing more and nothing less than complex movements of matter. Some of this style of working has been taken up under the label of actor-network theory. The second intervention draws more upon deconstructive traditions, and demonstrates the impossibility of a purely human subject (Badmington, 2000). In the latter the human project, or anthropological machine as Agamben (2002) has called it, can be demonstrated to be little other than an always partial differentiation of humans from non-humans, frequently taking the form of human/animal distinctions. While the second of working has been positively spun, involves ‘mixing wild imaginings with routine inventiveness, . . . [heralding] a politization of the technologies of life in which intellectual disputes and public controversies become inextricably entangled in the event of food scares, organ harvesting, genetic profiling and any number of other
post-industrial city

A city whose economic geography has passed from a dependence on manufacturing to an emphasis on service employment (see services). Typically, its dual labour market is characterized by a division between well-paid private- and public-sector professional and managerial workers and lower-paid service staff. The pattern of land uses and social areas in the post-industrial city shows marked variations from the arrangement in the classic concentric-ring model of industrial cities (cf. zonal model). The downtown skyline is now marked by new investment in office towers, public institutions, arts and sports complexes, and restaurant and leisure services. The brownfield sites of old industrial and transportation land uses around downtown have given way to waterfront redevelopment of condominiums and public leisure spaces, often the result of public-private partnerships. A number of inner-city neighbourhoods have experienced reinvestment and gentrification as the housing market responds to the downtown labour market of advanced services. New immigrants and the working poor are being displaced outward towards suburban sites, which have become the new focus of manufacturing and wholesaling, adjacent to the airport and regional highway routes. The suburbs are diversifying in lifestyle and social status, and with the emergence of satellite town centres (or edge cities in the largest metropolitan areas) are assuming a more urban status themselves.

The characteristics of the post-industrial city extend beyond its population and land-use features. Canadian studies indicate that the gender and family traits of post-industrial cities differ from those with a manufacturing base, with smaller households, a greater tendency for gender equality in the workplace, and lower and later marriage rates (Ley, 1980). Lifestyle liberalism and higher levels of secularism are among distinctive attitudinal and cultural associations.

Though typically experiencing economic and population growth, the post-industrial city faces significant challenges. Since the 1980s, neo-liberal policy has tended to trade welfare services for entrepreneurial objectives (Harvey, 1989a), accentuating social and spatial polarization (Walks, 2001). The emphasis upon quality of life considerations for the middle class might compromise provision of more basic services; for example, tax dollars expended on consumer attractions such as sports stadia could diminish the quality of life of more impoverished populations (Friedman, Andrew and Silk, 2004). Population growth and a large middle-class labour market are often associated with challenges to housing affordability (see housing studies). Underinvestment in public transportation has heightened the dependence on the private car, leading to traffic congestion and severe air pollution episodes. And, as the Paris banlieu riots of 2005 demonstrated so keenly, suburban sites may be a newly emergent zone of acute social exclusion.

Suggested reading

post-industrial society

A conceptualization of the changing conditions of economy and society in the global north, beginning approximately in the 1960s. The term was popularized by Daniel Bell’s immensely influential book (1999 [1973]), and has enjoyed widespread dissemination, though not always with the specificity that Bell intended. Post-industrial society is concerned with an occupational transformation in advanced societies, with automation and outsourcing, employment moves increasingly to a white-collar, service profile, with specialized information and information technology playing a key role in the shaping of society and economy. Beyond this, some authors see an evolutionary process, with societies passing through discrete economic and social stages from the harvesting of raw materials, to manufacturing, and finally to the provision of services aiding both consumption and production.

Through the 1970s, several variations on the theme of post-industrial society emerged. Influenced by the French student reaction against inaccessible state bureaucracies, Alain Touraine (1971) proposed that the holders of specialized information were becoming a privileged technocracy, extending control over growing domains of everyday life. A second stream of work emphasized the holders of specialized knowledge as a new middle class of professional and managerial workers, though internally fragmented by their variable access to economic and cultural capital and their location in the public and private sectors (Gouldner, 1979). A third track emphasized by Manuel Castells and his followers identified...
the role of information nodes and flows in the shaping of new social configurations.

The dominant figure, however, has been Daniel Bell. Although concerned with occupational transformations to a service society, his thesis went considerably further, as he sought to trace the forward trajectory of advanced societies, using the paradigmatic case of the USA, in the three interlocking domains of social structure, politics and culture. He noted a potential non-correspondence of the parts in this forward process, as, for example, a steadily more disciplined economy was tied to a steadily more antinomian culture. For Bell, a knowledge theory of value replaced a labour theory of value, and this opened up serious disagreement with Western Marxist theorists and more doctrinaire versions in Moscow (see marxism). By the mid-1980s, however, leftist critics were acknowledging the accuracy of Bell’s cultural and labour force projections (Wright and Martin, 1987). Nonetheless, Bell’s thesis, like all social theory, was a child of its time. Published as the unprecedented postwar boom was about to end, it is written from an overly optimistic and middle-class perspective, where scarcity and conflict do not deflect a track of upward social mobility. But it has proven a seminal paradigm for subsequent research, and its basic propositions are now part of the taken-for-granted world of contemporary social science.

post-Marxism Although the term ‘post-Marxism’ is sometimes applied to diagnose the post-Soviet era of geopolitics, this chronological usage trivializes an intellectual ferment that pre-dates the fall of the Berlin Wall by at least two decades. If calendar time is the touchstone, the year 1968 is a more precise marker of this cultural, aesthetic and intellectual movement that is suggestive rather than definitive. The prefix highlights an historical discontinuity in cultural expectations surrounding the relationship between society and the non-human world. The term captures the elevation of aesthetic and quality of life concerns over issues of production and distribution. Coined by Inglehart (1977), it describes the growth of environmentalism and the decreased dominance of class-based politics in the postwar era. Postmaterialism may be interpreted as an ‘ecology of affluence’ that is distinguishable from the ‘environmentalism of the poor’, whose ecological claims are rooted in the defence of livelihoods rather than quality of life (Guha and Martinez-Alier, 2000).

postmodernism An important architectural, aesthetic and intellectual movement that flourished in the latter quarter of the twentieth
century. It is easily (but mistakenly) conflated with its more philosophical contemporary, *post-structuralism*, as well as with the deeper currents (economic, political, social) signalled by its epoch-defining cousin, *post-modernity*. And though it is sometimes indistinguishable from the intellectual trajectories of the other two ‘posts’, most would agree to constrain it to the cultural sphere (see *culture*). Uncertainty exists as to whether or not postmodernism has ended, but clearly the excitement and controversy it generated has for the most part abated. While there is evidence that its roots are older, beginning in the 1960s and 1970s, many put postmodernism’s apex alongside the popularization of video media and the televisualisation of the Reagan presidency in the 1980s (or the politician’s digital counterpart, Max Headroom).

Broadly speaking, the thematics that characterize postmodernism’s artistic dimensions were said to constitute either a break from or an extension of the desire of *modernism* to turn the everyday and the mundane into *art*. Perhaps the most important result of this (dis)connection was the effort to take art out of the hands of the rich elite (historically, the main consumers of art) by collapsing the distinction between ‘high’ and ‘low’ aesthetic forms. The notorious tendency of postmodernists to blend multiple media in one work was often accomplished by combining forms that had previously been dismissed as vulgar elements of popular culture and thus marginalized in art – as in, for example, comic books, advertisements and graffiti. Modernist thematics often encouraged, if not required, reflection and contemplation about the layered meaning of a work, which was in some cases paired with the goal of faithfully recovering the artist’s intentionality. In addition, many modernist works highlighted themes of alienation, increased mechanization and rationalization. Postmodernism, to the contrary, often celebrated pastiche, depthlessness, multiplicity, uncertainty and fragmentation. In the hands of some postmodernists, history became less a reservoir of facts awaiting excavation than a playground of potential appropriations in which authenticity, timeless values and fealty to the truth were mocked by unceremonial gestures towards nostalgia.

Postmodern architecture concretized these concepts in the built environment. In contrast to modern architecture’s allegiance to functionality and its dismissal of ornamentation (Relph, 1987), postmodern designs were playful if not exuberant, aimed at creating confusion by overlapping and juxtaposing in contiguous spaces many different aesthetic styles. As in art, postmodern architecture was to pillage rather than revere history, borrowing elements such as Greek and Roman pillars and embellishing façades with touches of Art Deco. Postmodernism’s exchangeability of parts implied a relativistic approach to meaning, one that denies centres, or ‘depths’, of understanding (see relativism). Even the popular reflective windows of the 1980s were, according to Harvey (1989b), a flippant response to profundity, a refusal of a deeper inside that turns the gaze back upon the viewer.

That these architectural forms appeared alongside gentrification and a raging consumerism in the 1980s and 1990s was not lost on human geographers, and for the most part their reaction was unfavourable. Harvey’s (1989b) critique of the condition of modernity famously first situated postmodern urban forms within a set of deeper economic and political transformations (notably from Fordism to *post-Fordism* or flexible accumulation), and then explained what he regarded as the cultural ‘response’ (depthlessness, relativism, the ransacking of history etc.) as the surface-level outcome of dislodged sensibilities produced by *time-space compression* under late capitalism. Among the spaces read as signs of a distinctively postmodern spatiality were Baltimore’s revitalized harbour (Harvey, 1989b), Los Angeles’s Bonaventure Hotel (Jameson, 1984), New York’s South Street Seaport (Boyer, 1992), and Los Angeles and Orange counties, in California (Soja, 1989, 1992). Whether indited for presenting false history, structuring space for maximum surveillance, or attempting purposefully to disorient, each were tied in one way or another to the excesses of postmodernism. As Sorkin (1992b, p. 4; see also Goss, 1993) put it in describing Canada’s West Edmonton Mall, ‘Mirrored columns … fragment the scene, shattering the mall into a kaleidoscope of ultimately unreadable images. Confusion proliferates at every level; past and future collapse meaninglessly into the present; barriers between real and fake, near and far, dissolve as history, nature, technology, are indifferently processed by the mall’s fantasy machine.’ Another part of the urban underbelly of postmodernism was its socio-spatial segregation, denounced by Davis (1990) as ‘Fortress LA’ (1992), and described by Dear and Flusty (1998) as alternating between...
Dreamscapes of Privatopia and the Carceral City’s Mean Streets. As Smith (1996b) was to make clear within the context of gentrification more generally, the new spaces of the ‘revanchist’ city were not simply drawn by CAPITAL, but were forged out of an unholy alliance between it and the state. Looking back on these dreary accounts of postmodern URBANISM, it is hard to remember the democratically minded intentions of one of its most influential progenitors – Robert Venturi – who reacted against the sparseness of orthodox MODERNISM by collapsing the distinction between high and low architecture in his famous book, Learning from Las Vegas (Venturi, Scott Brown and Izenor, 1972).

Postmodernism elicited several different responses in HUMAN GEOGRAPHY. As the foregoing suggests, many of the first responses were influenced by postmodernism in architecture and planning (rather than literature or the creative arts more generally). Some saw in postmodernism’s attention to difference and the creative arts more generally). Some saw in human geography a form of irredeemably critical and affirmative LOCAL KNOWLEDGE (e.g. Ley, 1987, 1993, 2003a), while others saw an opportunity for a far more theoretically ambitious, insistently radical reconstruction of human geography writ large (Dear, 1986, 1988; Dear and Flusty, 2002). Many of these discussions were inspired in some measure by experiments in urbanism on the west coast of North America, notably Los Angeles and Vancouver, and they fostered the emergence and identification of a LOS ANGELES SCHOOL. One of its principal protagonists was Edward Soja, who straddled the postmodernism and postmodernity. These more architectonic versions of postmodernism as critical project (Soja) and critical object (Harvey) were roundly criticized by FEMINIST geographers in particular for their insensitivity to difference. These critiques were part of a growing interest in POST-COLONIALISM and post-structuralism that soon eclipsed postmodernism in human geography and beyond.

Today, the hullabaloo over postmodernism has waned, but it manages to live on in some contexts, including not only architecture but also, strangely enough, RELIGION. Part philosophical engagement inspired by poststructuralists such as Jacques Derrida (see Caputo, 1997; Caputo and Scanlon, 1999), and part a cultural wave of new Age, Eastern mysticism, this latest reconfiguration of postmodernism is paired against a disbelieving modernism, elements of which (see table) have been deployed in epic battles against religion.

How the religion–postmodernism nexus will evolve remains to be seen, but one thing is certain: whether we are in a state of MODERNITY or postmodernity, it will not take long for contemporary culture to construct nostalgia for postmodernism, making pastiche out of it as it did to everything else, serving up ironic quotations of the movement that gave new meaning to the term ‘irony’.

postmodernity Not to be confused with the cultural and aesthetic movement POSTMODERNISM, postmodernity refers to the contemporary historical period that arguably closed the door upon MODERNITY. The advent of the historical era and its associated artistic movement occurred during roughly the same period (the mid-to-late twentieth century), but the driving forces of postmodernity operate at a longer time-scale than do those of postmodernism (particularly now that the cultural form is into its dotage). While modernity was characterized by an insistence upon the possibility and knowability of ‘Truth’, postmodernity replaced its FOUNDATIONAL assumptions of solvability in scientific enterprises (see SCIENCE), universality in ethical imperatives (see ETHICS) and transcendence in the essence of things (see ONTOLOGY) with uncertainty, singularity and immanence. For better or worse (and it has certainly been both), the defining elements of postmodernity arose from a series of major transformations in the

fields of GEOGRAPHY and planning. Unlike Ley and Dear, however, he had a much more positive view of HISTORICAL MATERIALISM and of the (crucial) possibility of its spatialized reconstruction through a critical engagement with postmodernism (see Soja, 1989). Against this, however, as noted above, Harvey (1989b) mobilized his own historico-geographical materialism as a vigorous critique of
social, economic and political understandings about the how the world is materialized and experienced (Jones, Natter and Schatzki, 1995).

Intellectually, postmodernity is generally considered to be a period initiated by a thorough rupture in the history of Western thought, with its confident allegiances to what Jean-François Lyotard (1984) called ‘meta-narratives’ – grand theories of SOCIETY and human progress. These were thoroughly critiqued and often rejected by postmodernity’s more philosophical wing, POST-STRUCTURALISM, which was a concurrent response to STRUCTURALISM and its endless proliferation of binarized power relations. Post-structuralism quickly extended its critical scope to the hegemonic conceptual cornerstones of Western modernity, sometimes even back to their foundational theorizations in Greek PHILOSOPHY. More broadly, postmodernity’s historical break might be loosely described in terms of an avoidance of theoretical absolutism, an investment in epistemological constructivism (sometimes bastardized and mischaracterized under the slogan ‘everything is relative’: cf. RELATIVISM), a celebration of DIFFERENCE, a fascination with open systems and a devotion to complex relations of POWER (for a review of key thinkers, see Best and Kellner, 1991). Its rise alongside the information age inflects it away from modernity’s faith in our ability to accurately and adequately represent the world, and for some, such as Jean Baudrillard (1993), postmodernity’s products are not simply bad reproductions but ‘simulacra’, copies taken as more real than the reality that they represent (see REPRESENTATION; SIMULACRUM).

The uptake of these notions was in great part a response to the horrors that attended the rise of FASCISM and the HOLOCAUST. Often read by members of the postwar Frankfurt School (see CRITICAL THEORY) and later by post-structuralist thinkers as the logical culmination of the worst parts of modernity and as the political crisis to which all future ethico-political thought must respond, these events effectively signalled the end of an era. As postmodernity has progressed, its central ideas have been adopted and adapted for both progressive and quite cynical, reactionary ends.

By the late 1980s, it appeared that postmodernity and postmodernism were co-extensive, and indeed the intellectual fashions of the former fed the cultural currents of the latter. The geographer David Harvey sought to explain these connections in his 1989 book, The condition of postmodernity (see also Jameson, 1991; Soja, 1989). A testament to the broader importance of both ‘posts’ across the intellectual and popular landscape, the book was wildly successful inside and outside HUMAN GEOGRAPHY, making Harvey one of the most well known Anglophone theorists of the twentieth century. The argument draws primarily from Harvey’s reformulation of POLITICAL ECONOMY as an explicitly historicogeographical materialism, and situates both postmodernity and postmodernism within the transformations of SPACE and TIME (or, rather, time–space) brought about by the latest stage of CAPITALISM, which began to take on a new shape in the 1970s. As Harvey explained, the age of postmodernity was characterized by a series of growing CRISSES in capitalism, the results of which heralded a shift from a relatively stable set of production relations, FORDISM, exemplified by the capital–state–labour contract sealed by the New Deal in the USA, to the contemporary era of POST-FORDISM. When that contract expired under the weight of international competition for low wages, Western capitalists responded with JUST-IN-TIME PRODUCTION, a credit-based economy, and the spatial fixes of capital relocation and fresh market penetration. The new economy’s spatial, technological and labour processes had become, under the regime of FLEXIBLE ACCUMULATION, more nimble and quicker to change. Harvey’s argument was not, however, to draw a direct line of causality from these disruptions in the economic sphere to postmodernity’s seemingly similar loss of moorings in the intellectual domain. It was, rather, to couple these transformations through shifts in the ‘experience of space–time’; as he put it, economic change led to TIME-SPACE COMPRESSION, which dramatically redraw our cognitive maps of the social order. Into this confusion arose postmodernity, the result of a profound disenchantment with modernity’s long-held matrix of certainty and order. For its turn, postmodernism was simply a cultural blip, an ephemeral reaction in ART and architecture to the deeper anxieties brought forth by postmodernity (for an extended discussion, see Gregory, 1994, Part III, esp. pp. 406–14).

From Harvey, it follows that we should not welcome postmodernity as a new, emancipatory era that moves us beyond a confining, stodgy and conservative modernity, but see it rather as a description of forces that are deep, complex and surprising. And since 1989, arguably, things have intensified: the collapse of COMMUNISM, massive CONSUMPTION and even larger looming crises fuelled by
speculation, a troubling expansion of the privatization of state functions, high levels of economic inequality alongside increased racial and ethnic tensions, and a neo-liberal excitement for free markets for capital but sealed borders for labour (see neoliberalism). Meanwhile, all of these markers of instability are smoothed over with a blind, middle-class nostalgia for a media-invented image of modernity, democracy and white heteronormativity. Meanwhile, the exportation of cowboy capitalism to the global south serves to hide exploitative production practices and their associated environmental consequences from the eyes of northern consumers, while simultaneously exporting jobs and hardening borders. Finally, capitalism has had its own hand in the selective deconstruction of the notion of property, particularly in spaces in the south where indigenous rights are repeatedly trampled or simply ignored as opportunistic state leaders and corporations collude to exploit local resources in the name of the global consumer.

Within all of this we might find some optimism in the postmodern character of new social movements and alternative forms of political organizing, both of which have seen radical transformation in the late twentieth century as the union-based strategies of Fordism gave way to the post-NAFTA emergence of the Zapatista rebellion in Chiapas, Mexico. To the extent that postmodernity is associated with flexibility, so too goes resistance. Characteristic of the contemporary scene are roving protests against neoliberalism sparked by the successful disruption of the world trade organization meeting in Seattle, Washington in 1999; the emergence of hundreds of globally linked collectives of indigenous peoples, operating under a common proclamation of rights while preserving the singularities of their different political projects; and the widespread attraction of youth across the world to the ‘new anarchism’, to minor theory, to grassroots environmentalism, to living beyond racial and national identifications, and to sexual freedom. These contrast markedly to mobilizations under modernity, which insisted on coherence in political ideology and uniformity in goals for change (think global proletariat) – often toppled off by rigid organizational hierarchies. In their place, and taking cues from many post-structurally inflected approaches to feminism, anti-racism, queer theory, anti-statism and anti-capitalism, are thousands of collectives geared to produce radical change from the perspective of difference. Contemporary activists produce a continuously unfolding multiplicity of small, terminal actions that constantly work at ‘expanding the floor of the cage’ (in Noam Chomsky’s words) within which we currently find ourselves.

**Post-normal science (PNS)** Silvio Funtowicz and Jerome Ravetz (1993) contend that a new form of science is needed when ‘facts are uncertain, values in dispute, stakes high and decisions urgent’. The figure shows that where ‘decision stakes’ and ‘systems uncertainties’ are low, there is routine kuhnian science (see paradigm): when both are moderate, we have consultancy, which copes with uncertainty by working within tolerances and by professional judgement. But with high stakes and high uncertainty (the ‘post-normal’ condition), policy has to be implemented before the evidence is certain (cf. risk society). This requires new ways of working based on an ‘extended peer community’ (all those affected by an issue who are prepared to enter into dialogue) and ‘extended facts’, which include anecdotal evidence, confidential information, local knowledge and ethical commitments. As such, PNS aims to provide a coherent framework for participation in decision-making, which includes tools developed by Funtowicz and Ravetz to manage and communicate uncertainty and to allow for the qualitative assessment of quantitative information as provided by the NUSAP website (http://nusap.net/), and that goes beyond confirmatory
DATA ANALYSIS. As such, it provides an antidote to nihilistic relativism about facts, values and reality. Saloranta (2001) shows how PSN can be used in the climate change debate. KJ

post-socialism The various complex political and economic transformations occurring (particularly after 1989) in the former socialist states of Central and Eastern Europe and the former Soviet Union. It signals an historical break with models of social and economic development organized around a centralized bureaucratic STATE SOCIALIST project, a COMMAND ECONOMY, and the demise of the GEO-POLITICAL HEGEMONY of the Soviet Union over its satellite states. There is still debate about whether Chinese market socialism can be thought of as post-socialist with its opening of markets to foreign investment and export markets, and the expansion of private ownership in an ECONOMY still strongly controlled by the party state.

Post-socialism is also a description of a reorientation in a broader EPISTEMOLOGICAL and political structure of thought. Along with other similar 'postings' (such as POST-MODERNISM, POST-STRUCTURALISM and POST-COLONIALISM), post-socialism has signalled a conceptual break and has initiated a series of thorough-going theoretical transformations of socialist thought, as these others had with MODERNISM, STRUCTURALISM and colonial thought. With its enormous geographical scope and the depth of its impacts on regional and global economies, post-socialism has also reshaped the intellectual and institutional practices of many of the social sciences (e.g. the perestroika movement in political science, POST-MARXISM and rethinking MARXISM in economics, POLITICAL ECONOMY and GEOGRAPHY, and the resurgence of ANARCHIST thought and practice in SOCIAL MOVEMENTS and global justice movements).

Despite the salience of the historical changes wrought after 1989, post-socialism retains the binary nature of its origins. On the one hand, it represents one of the deepest politico-philosophical breaks of the twentieth century, the break with SOCIALISM and the return to the MARKET IDEOLOGY of Friedrich von Hayek. This break has fuelled the resurgence of NEO-LIBERALISM in former socialist states, particularly by the Bretton Woods organizations such as the IMF and World Bank. In this view, there is no alternative for reform societies but to privatize their economies, democratize their polities and liberalize their societies. De-communication must accompany structural adjustment, shock therapy and the building of open markets. On the other hand, post-socialism has also been a political-theoretical movement of socialist and social-democratic thinkers deeply concerned by the shocking deepening of social and economic inequalities produced by STRUCTURAL ADJUSTMENT and shock therapy, yet optimistic about the possibilities of what Jacques Derrida called 'DEMOCRACY-to-come' (Derrida, 1994). For such scholars, the technocratic implementation of shock therapy and the dire consequences for regional economies and livelihoods has been a cause for serious concern. From this perspective, the social and geographical contingencies of state socialism are matched by the deep complexities and contradictions of post-socialism (van Hoven, 2003). In response, geographers have explicitly challenged the dominant transition framework that examines organizational forms in Eastern Europe according to the degree to which they conform to or depart from the blueprints of already existing CAPITALISMS. In their place, they have focused on the diversity of 'actually occurring post-socialisms' (Grabher and Stark, 1997; Pickles and Smith, 1998).

With accession to the European Union, the geographies of post-socialist Central and Eastern EUROPE have become ever more focused on issues of regional and institutional INTEGRATION, the creation of common economic spaces, and issues of IMMIGRATION and LABOUR MARKET change. Here, post-socialism finally comes to mean something it probably ought to have meant much earlier; the process of regional change wrought on both sides of the Iron Curtain. JPi

post-structuralism A post-1960s intellectual movement that countered the perceived rigidities, certainties and essentialisms thought to characterize STRUCTURALISM. Yet post-structuralism has always been indebted to its predecessor, to which it is tied in productive ways (hence 'post-' and not 'anti-' structuralism). Post-structuralism was developed first in PHILOSOPHY and later took hold in literary theory and criticism (see CULTURAL TURN). Its birth is usually marked by a 1966 conference paper by Jacques Derrida (republished in 1978; also see Derrida, 1979). Other key figures and contributions include Foucault
POST-STRUCTURALISM

(1972a [1966], 1978 [1976], 1980b), Barthes (1977), Spivak (1988), Butler (1990, 1993a), Baudrillard (1993), Latour (1993), Bhabha (1994) and Badiou (2005). Often conflated with POSTMODERNITY and POSTMODERNISM, post-structuralism, while always in the mix of these theoretical and cultural currents, is more contained, analytic and philosophical. It has been, and continues to be, profoundly influential in the HUMANITIES and critical social sciences, and is noteworthy for underwriting many of contemporary HUMAN GEOGRAPHY’s engagements with ACTOR-NETWORK THEORY, FEMINISM, POST-COLONIALISM, POST-DEVELOPMENT theory, POSTHUMANISM, POST-MARXISM, PSYCHOANALYTIC THEORY, QUEER THEORY and SUBALTERN STUDIES. Its influence, direct and indirect, is felt in nearly all branches of human geography, though not without critics and dissenters, especially among humanists and Marxists (cf. HUMANISM; MARXISM). Its primary effects can be felt in four theoretical shifts since the 1980s:

(1) A rethinking of the relationships between the PRODUCTION of space and its REPRESENTATION, especially through reconfigured concepts of CULTURAL LANDSCAPE and LANDSCAPE, but also in other sites of TEXT and TEXTUALITY, such as LITERATURE, FILM, the MEDIA, MUSIC and so on.

(2) New concepts of what POWER consists of, where it is ‘located’ and how it operates.

(3) A destabilization of FOUNDATIONALISM, leading to post-foundational accounts of IDENTITY and DIFFERENCE (including critiques of standard categories in social science, such as CLASS and DEVELOPMENT), a questioning of the binary between CULTURE and NATURE, and a suspicion towards older and less reflexive understandings of OBJECTIVITY.

(4) A somewhat more recent reversal of post-structuralists’ tendency to privilege EPISTEMOLOGY over ONTOLOGY in accounts of social life.

Jacques Derrida’s version of post-structuralism is fundamental to the destabilization of meaning that lies at the heart of the concept. He began with the recognition that any structure relies upon a centre, an organizing principle (e.g. God, the individual, truth, objectivity), around which the remainder of the structure is constructed. Derrida then famously unhinged the centre from its effronteries of self-actualization and independence by asserting its relational constitution with an ‘other’, an outside periphery that is the raw material for the centre’s construction. In helping forge the identity of the centre through a process of negation (i.e. not ‘other’), this ‘constitutive outside’ is said to leave its ‘trace’ within the centre, highlighting their co-dependence and providing the entry point for the post-structuralist method of DECONSTRUCTION, a form of analysis that demonstrates the reliance of the centre on its excluded other (cf. DISCOURSE ANALYSIS). Derrida’s main contribution in human geography has been to help undo the security of traditional binaries, such as objectivity/subjectivity, SPACE/PLACE and nature/culture.

Foucault’s brilliant contribution to post-structuralism was to trace the historical evolution – or GENEALOGY – of socially constructed categories and to ask in whose name and in what contexts certain objects became associated with certain categories. His work typically linked analyses of the interrelated production of institutions (hospitals, PRISONS: see CARCEL GEOPHIES; PANOPTICON), scientific and political discourse (see CRITICAL GEOPOLITICS) and their subjects (see DISCIPLINARY POWER). Further, it led him to envision capillaric rather than fixed sites of POWER, which operates as a difference-naming and boundary-drawing effect of DISCOURSE. Probably the most influential of the post-structuralists to date, Foucault’s impact on studies of space have been plentiful: in studies of GOVERNMENTALITY (counting and placing bodies), identity (naming bodies in terms of race, deviance, health etc.) and SEXUALITY (controlling BODIES and populations: see BIOPOWER), as well as in post-structuralist studies of landscape, where discourse and space meet, and where the operation of power is concretized (see Crampton and Elden, 2007).

FEMINISM has a complicated relationship to post-structuralism. On the one hand, Butler, within the context of feminism and queer theory, described the production of the human SUBJECT as a matter of PERFORMANCE, signs acted out upon – through iteration and citation – the bodies of individuals. Like Foucault, Butler rejects any notion of an innate subject, suggesting that PERFORMATIVITY is a matter of approximating idealized imaginaries of gender, and of resisting or even satirizing such ideals. (Geographers have mostly taken up performativity by insisting on the context-specificity within which identities are formed.) On the other hand, some feminists have not welcomed the destabilization of identity that post-structuralism heralded, noting that the rise of anti-essentialist
thought was curiously coincident with women’s successes in demanding a voice based on sex and gender (see Nicholson, 1989). In any case, a number of concepts and debates within feminist geographies are intimately tied to the rise of post-structuralism (see alterity; body; difference; essentialism; identity; positionality; subjectivity).

The above thinkers have an aversion to metaphysical or ontological speculation, and so it has been said that, in their tradition of theorizing, epistemology trumps ontology (Dixon and Jones, 1998). But Deleuze (1994) never refrained from attempting to develop a thoroughgoing post-structuralist philosophy that incorporated ontology. Central to this – and what makes it possible to consider Deleuze a post-structuralist – was his rejection of all conceptions of the world that relied upon transcendental or ideal objects, such as essences (see also minor theory: see Katz, 1996). Instead, he describes an immanent universe of force and affect, one that organizes itself according to the matter (literally) at hand. Thus, things in the world do not correspond to a set of ideal forms, but are instead singular products of continuous material differentiation. Thought – by its very nature, but particularly so under modernity – retrofits objects and relations into categories and orders of similitude, and thus keeps the thinker at a conceptual distance from the ‘pure difference’ expressed by the material world. As his is an approach that often has more in common with complexity theory than dialectics, Deleuze too has been controversial among some post-structuralists and many Marxists. Together with his colleague Félix Guattari (see Deleuze and Guattari, 1987), he developed a rich spatial vocabulary populated with concepts such as assemblage, nomadology, rhizome, (de)territorialization, smooth and striated spaces, and the like (Bonta and Protevi, 2004; see also Doel, 1999).

Poverty A much-contested term that suggests a state of welfare/illfare in which a person cannot function in one or more respects as a capable human being. Poverty is not a term that is easily defined. In so-called ‘poor’ or ‘developing’ countries, attempts are often made to define poverty in ‘absolute’ or nutritional terms. The official definitions and measurements of poverty used in India highlight some of the complexities and challenges associated with this category. The Government of India tracks the number of people in the country who cannot purchase enough commodities to ensure that they get on average 2,400 calories per day in rural areas or 2,100 calories per day in urban areas. These are aggregate figures that are collected at the household level by the census authorities or by officers of the National Sample Survey. Attempts are also made to count the number of women or children in absolute poverty, or people in female-headed households or those over 60. The Indian government maintains that the head-count ratio of people living below the poverty line has halved since 1973–4, coming down from about 55 per cent of the population to about 26 per cent of the population in 1999–2000. This still amounted to more than 260 million people. Independent scholars have challenged the India’s government data and generally put the 2000 figure at 300–350 million people.

About one in five people who suffer from absolute poverty live in India, despite recent progress there. Rates of poverty are higher for females than for males. It has also been estimated (Sen, 1990) that more than 100 million women are ‘missing’ in South Asia and China as a result of gendered social practices before and after birth (female abortion and infanticide, male preference in feeding and health care). Yet it is Sub-Saharan Africa that generally comes to mind when discussion in Northern countries turns to absolute poverty. It is here that Jeffrey Sachs, the American economist and adviser to Ban Ki-Moon at the United Nations, has demanded action to secure ‘the end of poverty in our lifetime’. Sachs (2005) has called for the elimination of what he calls ‘extreme poverty’ by 2025. He wants the US government to impose a 5 per cent income tax surcharge on Americans earning more than $200,000 per annum. This will generate over half of the $70–80 billion per year that he reckons is necessary to kick-start economic growth in the poorest countries. The remaining funds must come from other richer countries. Such concerted spending, Sachs argues, can ensure that the first Millennium Development Goal is met – the UN-agreed target of halving between 1990 and 2015 the proportion of people whose income is less than one US dollar a day. It might also eliminate extreme poverty and hunger by 2025, particularly if increased aid spending is directed not only towards...
ECONOMIC GROWTH, but also to better educational provision and HEALTHCARE delivery, including for HIV/AIDS patients.

Not everyone agrees with Sachs’ vision of what causes absolute poverty (he directs a lot of attention to PHYSICAL GEOGRAPHY) or his suggestion that it is best addressed by massive programmes of public spending (see also DEVELOPMENT). Part of the reason for this is that Sachs is mainly concerned with calorific or income poverty. Adam Smith famously argued that a definition of poverty should include the right not to feel shame in public. In other words, he recognized that people cannot function in ways that they might want to if they are the targets of physical or verbal abuse. This tradition of thinking has been continued by John Maynard Keynes and Amartya Sen. One virtue of Sen’s (2000) work is that it directs us to think about poverty in relational – and not simply absolute – terms. What matters, Sen suggests, is whether we have the capability to live our lives in ways that we consider meaningful, however differently we might define what a meaningful life is. This is partly qualified, for Sen, by the prior requirement that all human beings must have a minimal level of food intake, shelter, education and health to function as humans. One can imagine a family in Punjab, then, that is above a state-defined poverty line. Perhaps the family has benefited from rising incomes as a result of the GREEN REVOLUTION. But what if females in the family lose paid jobs to male kin, perhaps on the basis that their labour in the fields is no longer ‘required’? What if this loss of earning power translates into a system of purdah, where women find it harder to venture into public space? For Sen, this can also be a sign of poverty, precisely because it defines a gendered system of SOCIAL EXCLUSION. The same argument can be extended to members of social groups who are not allowed to worship with others, or who cannot easily draw WATER from public wells (Erb and Harriss-White, 2002).

This way of thinking about poverty also directs attention to social norms and thus to the geographical nature of poverty. In richer countries, ‘poverty’ is most commonly defined as relative deprivation, and here as elsewhere it tends to be feminized (Jones and Kodras, 1990; but see also Chant, 2006). People are considered to be poor relative to some assumed bundle of goods or services, or of capabilities and functionings, that provides for at least a minimum level of access to what is considered ‘normal’ in a given social setting. For example, in the USA, not having a television set might be considered an index both of social exclusion and of relative deprivation, at least where this is not an active family choice. Once the word ‘normal’ comes into play, however, we recognize that ‘wars on poverty’ are discursive constructions and not just political campaigns (Yapa, 1998: see DISCOURSE). Social scientists now pay close attention to the powers of state and non-state actors to define ‘poverty’. They also look at the governmental effects of describing someone as poor, or, as in India, as a Below Poverty Line (BPL) person or household (Corbridge, Williams, Srivastava and Véron, 2005). Work on these issues is being published alongside academic research on poverty, inequality and GLOBALIZATION in the world economy (Wade, 2004; Wolf, 2004). There is clearly room for both types of work: for studies that are sharply attentive to the cultural constructions of poverty and its effects in different locations, and for studies that carefully seek to map out what has been happening to absolute poverty in the developing world (with and without considerations of India and China, whose enormous size affects all calculations) in an age of apparently increased spatial interdependencies.

**poverty gap** POVERTY is conventionally measured in terms of an **Absolute Poverty Line**, expressed in monetary terms: it is the income or expenditure below which a minimum nutritionally adequate diet plus essential non-food requirements are no longer affordable (e.g. spending per capita of less than US$1.00 a day, which is the conventional measure or threshold for the Absolute Poverty Line everywhere). A poverty line distinguishes, then, the poor from the non-poor (Ravallion, 1995; UNDP, 1998). Poverty estimates are typically based on data from actual HOUSEHOLD budget or income/expenditure surveys. In this way, a proportion of a country’s population or an absolute number of persons or households can be designated as living in absolute poverty: this is the **Head Count Index**. Currently, for example, it is estimated that 47 per cent of the population in Nigeria live in absolute poverty. Using this Absolute Poverty Line, it is possible to calculate what proportion of the GDP of a country would be required to lift those in absolute poverty above the poverty line (e.g. the proportion of
Nigeria’s GDP that would be required to lift the 70 millions who are absolutely poor to a condition in which their basic needs were fulfilled). This is the poverty gap: the poorer the country and the larger the number of people in poverty, the greater is the gap (i.e. the resources that must be devoted to raise those in poverty). The poverty gap thus speaks to the scale and depth of poverty, and what it would take as a measure of national output to bring all of the population above the poverty line. The Poverty Gap Ratio refers to the mean distance below the $1 a day poverty line expressed as a percentage of the poverty line (currently 34 per cent for Nigeria). The Poverty Gap Index refers to additional money the average poor person would have to spend (in aggregate or as a proportion of total consumption) in order to reach the poverty line. The poverty gap for India is currently 4 per cent, for China 1 per cent and for eastern Europe 0.1 per cent. The Poverty Severity Index measures the distribution of welfare of those below the poverty line (i.e. between the poor and the ultra-poor).

**power** A minimal definition of power would refer to the ability of one agent to affect the actions or attitudes of another. Like most concepts that are central to social science, the meanings, causes and effects of power are continually being re-assessed. One thing we know for sure is that it is trite to think of power only in negative terms. The possibility of having a conversation with someone, of running a class or seminar in which people can learn, of playing a football match, depends upon the deployment of power: of people taking turns to speak and listen, of students and teachers doing work as agreed, of players deferring to a referee. People both exercise power and are on the receiving end of power at different times every day, in all realms of life. More important than the fact that power is exercised is the way in which power is constructed and deployed. To what extent is power concentrated in certain institutions, relationships or agencies? How visible is it? What are the opportunities for power relations to be contested or rotated? Are accountability mechanisms in place, and if so how well do they work?

The idea that power is fundamentally negative continues to be a powerful one, even when it is coupled with an idea of necessary restraint. Thomas Hobbes (1668 [1651]) argued that all men (sic) acted as egoists, bent on the satisfaction of their desires through relentless power plays. Given a world of scarcity, only the sovereign could prevent these individualized acts of power from adding up to an intolerable state of nature (cf. sovereign power). Contemporary work on international relations by so-called Realists presents a similar view of power, in which all states seek to maximize their self-interest and are prepared to use violence to this end. Anarchy is prevented only by the exercise of hegemony by a dominant power. Some versions of Marxism come close to this argument. Marxists argue that capitalist states deploy their power to guarantee the accumulation process under the rule of capital. It is not surprising, then, that many Realists and Marxists share the view that the war in Iraq was fundamentally about oil and the protection of America’s self-interest. As David Harvey puts it in The new imperialism, joining Marx to Mackinder, ‘Whoever controls the Middle East controls the global oil spigot and whoever controls the global oil spigot can control the global economy, at least for the near future’ (2003b, p. 19).

Of course, there is more to Marxism on power than a perspective on international relations. Marxist work on power in human geography first made its mark through a critique of behavioural and pluralist models of power. These models, developed by political scientists such as Robert Dahl to look at power coalitions in US cities, emphasized the overt and dispersed nature of power. Power could be observed when A made an open attempt to force B to do something that s/he would not otherwise do. If A succeeded, s/he had power in this ‘issue area’. Happily, however, or so Dahl (1963) concluded, B would probably exercise power over A in another issue area. Given the nature of democracy in the USA, power was hard to monopolize.

Radical scholars disagreed. Steven Lukes (2005) argued that this view of power was one-dimensional. The work of power was most often done in smoke-filled rooms and in the setting of agendas. Lukes referred to this as two-dimensional power, and he did not stop there. Lukes further argued, as did many Marxist geographers (see Marxist geography), that not only were agendas bent to serve certain class interests (not least through the state), but also that many people at the wrong end of power were unable to see their powerlessness. In part, this is because of what Marxists call ‘false consciousness’. Ordinary people cannot see their ‘objective interests’, because their political antennae have been deadened by years of watching sport, shopping
POWER-GEOMETRY

in the mall or buying into the dream of a better life within CAPITALISM (see IDEOLOGY).

In the 1980s, cultural and political geographers began to explore some of these constructions of HEGEMONY, drawing usefully on the work of Antonio Gramsci. FEMINIST GEOGRAPHIES also explored the different ways in which relations of PATRIARCHY were embedded and understood in different parts of the world (Rose, 1993), and explored questions of RESISTANCE to power, including discussions of the weapons of the weak (Hart, 1991; see FEMINIST GEOGRAPHY). In the 1990s these explorations were significantly extended as geographers began to draw more broadly on the work of Michel Foucault, and through him the work of Edward Said and other theorists of POST-COLONIALISM or POST-STRUCTURALISM. John Allen (2003) has suggested that power can be thought of as an inscribed capacity inhering in certain agents and NETWORKS; as a RESOURCE; and as a set of strategies, DISCOURSES and technologies of government (see BIOPOWER; DISCIPLINARY POWER; GOVERNMENTALITY). This last view of power begins to hint at the richness of Foucault’s legacy to the human sciences. Foucault (2001) recognized, as some of his followers have noted, that power can be enabling. For the most part, however, geographers have read Foucault as a guide to the ways in which power inhabits and flows through all of the ‘capillaries’ of modern life. They have also taken from Foucault the notion that power is strongly territorialized. It is embedded in jurisdictions that run from the human body (powerfully disciplined by ideas of ‘normal’ SEXUALITY, for instance), through the organization of schools, hospitals, asylums (Philo, 2004) and PRISONS, and on to the construction of BOUNDARIES that express ideas of inclusion and exclusion. Power, in this view, can be challenged, critiqued and contested – this is the job of an oppositional social science – but it cannot be transcended: the line to Foucault runs through Weber and Nietzsche more strongly than it does from Marx.

The idea that power animates all spatial practices, and that power is always spatialized, is now widely understood in GEOGRAPHY. So too is the idea that power is most effective when it is least visible. CRITICAL HUMAN GEOGRAPHY seeks to denaturalize some of the most powerful discourses that are at play in the subject – ideas of DEVELOPMENT, for example, or the WEST, or WHITENESS. In so doing, it aims to reveal other ways of assembling power and knowledge. At the same time, however, as Harvey’s work on the new IMPERIALISM reveals, some geographers are also concerned to keep their eyes focused on materialist conceptions of power, and the powers of CAPITAL and the STATE. When it was revealed that the Bush administration in the USA was pursuing a policy of ‘extraordinary rendition’ (the alleged torturing of suspected ‘terrorists’ in prison camps outside the USA), it became clear that work on the sovereign powers of states (Agamben, 1998; see EXCEPTION, SPACE OF) had to be linked to work on spatial strategies of demarcation, Othering and distanciation (see Gregory, 2004b, on the Israel–Palestine conflict), and to robust accounts of the deployment of US power in an age of NEO-LIBERALISM (Smith, 2005a). power-geometry The more or less systematic and usually highly uneven ways in which different individuals and groups are positioned within NETWORKS OF FLOWS and interactions. These variable positions derive from the intimate connections that exist between productions of POWER and productions of SPACE: spatial modalities of power are differentially engaged such that different actors in different places have different degrees of freedom. The concept was proposed by Doreen Massey (1993) as both a critique of David Harvey’s concept of TIME–SPACE COMPRESSION and an attempt to open up conventional, ‘bounded’ conceptions of PLACE.

Massey (1993, pp. 60–1) argued that Harvey (1989b) had emphasized CAPITALISM to such a degree that his account of time–space compression collapsed into an economism, and paid so much attention to CLASS that he failed to acknowledge the wider range of social positions that were involved, including GENDER. In short: TIME–SPACE COMPRESSION ‘needs differentiating socially’. In parallel, Gregory (1994, p. 414) argued that the process also needs to be differentiated spatially: there is a complex geography to time–space compression. The concept of a power-geometry speaks to these twin concerns. It was developed independently of ACTOR–NETWORK THEORY, with which it has some affinities, but it provides a multidimensional conception of space that is intended to be unwaveringly political in its orientation.

POSITIONALITY is crucial to power-geometry (see also Sheppard, 2002). From the outset,
Massey (1993, p. 63) emphasized the politics of mobility that derive directly from different positionalities within a particular power-geometry: ‘We need to ask whether our relative mobility and power over mobility and communication entrenches the spatial imprisonment of other groups’. For Hyndman (1997, p. 151), this remains a promissory note, and Massey does not delve far enough into the economies of power that regulate, facilitate and disrupt transnational movement. Although her argumentation-sketches are often impressionistic and usually operate at a high level of abstraction, Massey’s later writings are nonetheless directed towards the elaboration of what she calls ‘a global sense of place’. For her, places are open, porous and hybrid – literally, ‘meeting places’ within which trajectories of all kinds (people, ideas, commodities) collide – and to represent them as containers, building blocks or objects (cf. regional geography) is to foreclose the possibilities of an intrinsically spatial politics. This openness is not a peculiarity of modern globalization and cannot be reduced to the choreography of contemporary capitalism. Over the long term, she proposes, different places have been drawn into engagement with one another in a ‘power-geometry of intersecting trajectories’ (Massey, 2005, p. 64), but there is no single, plenary narrative within which these can be convened (p. 82); the outcomes of these intersections have always been open-ended (though not, of course, unconstrained) because the spatial is ‘the realm of the juxtaposition of dissonant narratives’, and it is out of this ‘thrown-togetherness’ that new narratives are generated and negotiated (pp. 140–2). Seen thus, power-geometries not only shape and constrain mobility: they are themselves in constant if irregular motion, so that their analysis is necessarily both historical and geographical (cf. contrapuntal geographies). Place can then be recognized as ‘woven together out of ongoing stories, as a moment within power-geometries, as a particular constellation within the wider topographies of space’ (Massey, 2005, p. 131).

pragmatism An American tradition of philosophy that emerged in the late nineteenth century associated with John Dewey (1859–1952), William James (1842–1910), George Herbert Mead (1863–1931) and Charles Sanders Peirce (1839–1914) (see Barnes, 2008a). The movement is best known for the idea that what counts as knowledge is determined by its usefulness. As James (1987, p. 578) wrote, ‘the true is the name of whatever proves itself to be good in the way of belief’. Pragmatism is thus a philosophy of practical achievement. Ideas are labelled true when they enable humans to get things done, to cope with the world. After enjoying widespread popularity in the first half of the twentieth century, pragmatism fell out of favour after the Second World War following the ascendancy of empirical social science and analytical philosophy, a narrowly conceived, often technically abstruse form of reasoning concerned with assessing the coherence, consistency and precise meaning of an argument. The publication of Richard Rorty’s Philosophy and the mirror of nature (1979) revived pragmatism’s fortunes, however. As an ex-analytical philosopher, Rorty diagnosed with forensic precision the pathology of modern philosophy, prescribing as cure a large dose of American pragmatism. Now found in a range of humanities and social sciences, the rehabilitation of pragmatism is also a consequence of the wider interest in post-structuralism and postmodernism, movements with which it shares common interests.

James coined the name pragmatism in 1898 to describe the movement, but there were always strong differences among its proponents. At one point, for example, Peirce minted his own neologism, ‘pragmaticism’, to mark off what he was doing from his colleagues, and sufficiently ‘ugly to be safe from kidnappers’ (Bernstein, 1992a, p. 813). Bernstein (1992b, appendix) usefully characterizes pragmatism by five features:

(1) Anti-foundationalism, the belief that there are no secure anchors either in the world or in the mind that holds and guarantees the permanency of true knowledge.

(2) Fallibilism, the belief that no truth is ever final, and that knowledge should always be subject to further investigation, critical scrutiny, and questioning.

(3) Communal enquiry, the notion that scholarship takes place within a wider community involving trust, conversation, and shared norms and responsibilities.

(4) Radical contingency, the belief, stemming partly from Darwin’s theory of evolution, that change is propelled by chance and accident, that the only certainty is uncertainty (and for this reason humans must always be ready to expect the unexpected) (cf. darwinism). Peirce
PRAGMATISM

(1982, vol. 4, p. 544) wrote, ‘Everything that can happen by chance, sometime or other will happen by chance. Chance will sometime bring about a change in every condition.’

(5) ‘Radical pluralism’, the belief that neither bits of the world nor of philosophy coherently fit together all of piece. Radical pluralism, as James (1977, p. 26) writes, is a ‘turbid, muddled, Gothic sort of affair without a sweeping outline and little pictorial nobility’. But for James it is all we have.

The rise of analytical philosophy in America from the 1940s brought with it everything that pragmatism formerly shunned – foundationalism, certainty, individual rationality, necessity and monism. Consequently, pragmatism was pushed, and sometimes shoved aside. After his death Dewey, for example, was regarded by one analytical philosopher as ‘a nice old man who hadn’t the vaguest conception of real philosophical rigor or the nature of a real philosophical problem’ (quoted in Gouinlock, 1972, p. xi). Analytical philosophy’s hold on the profession was relatively short-lived, however, and by the 1980s it was vigorously challenged by a new group of pragmatists, including Richard Rorty (1931–2007) and Richard Bernstein (b.1932).

Rorty, drawing upon the writings of Dewey and James, seeks first to dismantle from the inside out the edifice of contemporary analytical philosophy, especially the variant known as realism; and, second, to substitute for it, a neo-pragmatic alternative which he calls, possibly tongue-in-cheek, ‘postmodernist liberal bourgeois irony’ (Rorty, 1989). Very briefly, Rorty argues that the problems of analytical philosophy stem from its appropriation of an inappropriate metaphor, vision or sight, or ‘ocularism’. The metaphor mistakenly convinced philosophers that it was possible for the mind to mirror the world (cf. vision and visuality). In contrast Rorty, following the pragmatists, argues for a different central metaphor, ‘conversation’. Under this model there are no fixed end points, strict rules or necessary logics. This is evident by unpacking the terms of Rorty’s alternative: ‘postmodernist’ because Rorty does not believe in the grand metanarratives of high modernism that supposedly make all parts of the world commensurable; ‘liberal’ because for the conversation to continue there must be freedom of expression and democracy (thereby echoing Dewey’s concerns); ‘bourgeois’ because Rorty thinks that liberalism has so far only been possible under capitalism; and ‘irony’ because for the conversation to continue we need to affirm certain beliefs even though there are no firm philosophical foundations for them. Rorty approvingly quotes Joseph Schumpeter (1942, p. 243), who says that one needs ‘to realise the relative validity of one’s convictions and yet stand for them unflinchingly’.

While sympathetic to many of Rorty’s ideas, Bernstein (1992b, ch. 8) is sharply critical of his economic conservatism, and his disengagement from questions of unequal power and resources. Bernstein (1992b, p. 233), says that Rorty’s version of pragmatism is ‘little more than an apologia for the status quo’. In contrast, Bernstein deals with those absences by joining to pragmatism various strands of continental European philosophy, producing what he calls ‘the new constellation’ (Bernstein, 1992b). An important component within Bernstein’s mix are writers identified with post-structuralism such as Foucault and Derrida, who are not economic conservatives, and who deal vitally with questions of unequal power and resources. In no small part, the renaissance of American pragmatism is a result of its resonance with the concerns of those writers.

In human geography, there have been sporadic, but neither consistent nor concerted, attempts to draw upon pragmatist writers. Jackson and Smith (1984) utilize Mead’s more applied prescriptions in their portrayal of social geography; Westcoat (1992) describes the relation between White’s environmental outlook, and particularly Dewey’s ideas; both Barnes (1996, chs. 2 and 5) and Gibson-Graham (2006b [1996]) make use of Rorty’s work in countering essentialism in economic geography; and Sunley (1996) takes the ideas of another ex-analytical-philosopher-turned-pragmatist, Hilary Putnam, and puts them to work in a discussion of the relationship between the new institutional economics and economic geography. A special issue of Geoforum (2008) is devoted to assessing the usefulness of pragmatism for human geography and connecting it to contemporary intellectual formations: thus Allen (2008) conducts a series of radical experiments that insert pragmatism into the play of power, Bridge (2008) reactivates pragmatism in theorizations of performativity and spatiality, while Jones (2008) identifies a series of connections between pragmatism, post-structuralism and non-representational theory.
prediction The construction of an estimated or expected value for an observation being studied, where the observation might be for a place, region, individual or time-period. The estimate or prediction may be generated by a statistical model (e.g. regression), a mathematical model (e.g. an entropy-maximizing model) or a more informal simulation process. The term ‘predicted value’ is usually employed for the ‘fitted’ or estimated values for observations within the data set being calibrated or modelled, and the out-of-sample extrapolation is termed the forecast.

pre-industrial city All cities prior to the Industrial Revolution, plus those in non-industrialized regions today. The term reflects the theory, initially advocated by Gideon Sjoberg (1960; see Sjoberg model), that all pre-industrial cities, regardless of their time, place or cultural backdrop, share similar reasons for existence, social hierarchies and internal spatial structures. The term is now rarely used, as few researchers believe that the variety of urban forms created by pre-industrial and non-industrialized societies have enough in common to be considered as variations of a single category.

preservation The protection, maintenance and care of relict features of the built environment, including historic buildings, archaeological sites and individual human artefacts (e.g. the Colosseum in Rome). Preservationists complement the work of conservationists, who aim to protect specific ‘natural’ landscapes or features of the biophysical environment (e.g. the Grand Canyon) (cf. conservation). Agencies such as the National Trust in the UK are awarded statutory powers to preserve houses and gardens of particular historical significance (see heritage). This may involve the extensive restoration of buildings to bring them back to their original condition or their revival through the reproduction of past features (e.g. gardens). Human geographers have been concerned both with the practices involved in preservation projects and with the types of landscape imagery, iconography and interpretation provided in preserved landscapes (e.g. Ashworth and Tunbridge, 2004). As the example of the Colosseum suggests, however, ‘preservation’ has a complex and often contentiously imaginative relationship with restoration (see Hopkins and Beard, 2005, chs. 1 and 6; and, more generally, Lowenthal, 1985). Relict features typically have multiple, sedimented histories inscribed in and on them: they are not the product of a single historical moment. It was for this reason that the French architect Viollet le-Duc (1814–79) argued that restoration should restore a building to an idealized state of completion, perfection ‘that may never have actually existed at any given time’: which is why, in turn, his ‘restorations’ (e.g. of the French city of Carcassonne) proved so controversial in the past and in the present.

pricing policies The arrangements whereby the prices at which commodities are offered to consumers are determined. In spatial economic analysis, the important distinguishing feature of pricing policies is the extent to which price varies with distance from the origin or source of the commodity. There are two major alternative policies. The first is known as the f.o.b. (free on board) price system, under which there is a basic price at origin and the consumer pays the transport cost involved in getting the commodity to the point of purchase. The second is the c.i.f. (cost, insurance, freight) price system, under which the producer adds insurance and shipping cost to the production cost and offers the commodity at a uniform delivered price irrespective of distance from origin. The distinction between these two policies is important, for commodities sold c.i.f. should have no bearing on location comparative advantage for productive activities requiring them as inputs; similarly, distance from origin should not affect level of demand for goods offered on a c.i.f. basis (other things being equal). There is an increasing tendency for commodities to be sold at a uniform delivered price.

 Various alternative pricing policies may be implemented. An f.o.b. system does not necessarily have minor incremental increases in price for small increases in distance; more often, the prevailing freight rates on which delivered price is based will be constant over broad zones. There may be forms of spatial price discrimination, under which customers in some areas are charged a high price (perhaps because the supplier has a local monopoly) so as to subsidize the price charged in a more competitive market elsewhere. A well-known variant is the basing point price policy,
primary data analysis  In contrast to secondary data analysis, this involves data collected and analysed by the same researchers. This allows a great deal of control over what is collected and how it is collected, so that there can be high coherence between theoretical and operational concepts. Such an approach can be costly in time and resources, however, and there can be a lack of compatibility with other work in the field; use of resources such as the Question Bank (http://qb.soc.surrey.ac.uk/) and of harmonized questions in survey analyses can ameliorate the latter problem, while effective sampling can address the former.

primate city, the law of  An empirical regularity identified by Mark Jefferson (1863–1949: see Jefferson, 1939). The populations of the three largest urban areas in some countries approximated the ratio sequence 100 : 30 : 20, which he attributed to the largest city’s pre-eminence in economic, social and political affairs. Although the sequence is now largely ignored, the concept of primacy, implying a city’s predominance within an area, is frequently deployed (cf. hegemony; rank-size rule).

primitive accumulation  In Capital I, having explained the laws of development of capitalism, and the distinctive features of the capitalist mode of production, Marx turns to the process by which capitalism historically established itself (Marx, 1967 [1867]). To pose this historical question – how did capitalism arise? – Marx focuses not simply upon the way in which one set of relations of production is transformed into another – the transition from feudalism to capitalism – but on how one class of workers, defined by their lack of property, came to confront another, capitalists, who monopolized the means of production. The ‘so-called secret’, as Marx terms it, of primitive accumulation resides not in the simple expansion of the provision of the means of production in a quantitative sense but, rather, in a revolutionary reorganization of the relations of production. Primitive accumulation for Marx was, in other words, the process by which a pre-capitalist system of largely agrarian relations and small-scale property holding – a peasantry having some form of direct control over the means of production, namely land – was dispossessed. The origins of capitalism are to be found in the process by which the peasants are freed – there is much irony in Marx’s use of this word – to become wage labourers in agriculture (on large commercial estates) and in industry. Marx turns to the case of the enclosure movement in Britain – in effect, the violent expropriation of forms of common property – and the political and extra-economic means by which this long process of the creation and disciplining of a proletariat was achieved. Marx made it clear that this process always required the powers of the state and was necessarily violent – written in blood and fire, as he put it (see violence).

In seeing the enclosure movement as paradigmatic of primitive accumulation, Marx opens up a complex debate over the transition from feudalism to capitalism and how other parts of Europe, and subsequently the colonial and post-colonial world, stood in a different relation to the ‘original sin’ of primitive accumulation. The debate between Dobb and Sweezy (see Hilton, 1976) turns precisely on the interpretation of other European experiences and the weight attributed to the role of exchange and market transactions as the force in the disintegration of pre-capitalist relations, or whether the pre-capitalist solidity was broken by the dynamics of class structure and struggle over property (see Brenner thesis). These debates were, of course, central not only to the origins of capitalism in Europe but to the dynamics of capitalism at the ‘periphery’; that is to say, how forms of capital took hold of agrarian societies in the context of European empire (the first age of empire) and the genesis of a mercantile world system.

The primitive accumulation question has always been central to the agrarian question; that is to say, the ways in which peasant systems of production are differentiated as capital takes hold of production. Much of this work dates back to the classic studies of land, labour and markets instigated by Karl Kautsky (1888 [1899]) and Vladimir Lenin (1964) in their studies of German and Russian agriculture.
In the 1960s, the boom in peasant studies increasingly focused on the land and landed inequality question; for example, how the green revolutionary technologies were (or were not) producing an agrarian proletariat (Harriss, 1982: see Green Revolution). Primitive accumulation has also been central to theories of imperialism, building upon Marx’s observation of the ways in which colonialism dispossessed Third World property holders and laid (or attempted to lay) the foundations for systematic accumulation. In so many cases, colonial capitalism proved to be dominated by merchant and other forms of capitalism, in which the speed and depth of proletarianization was often constrained (Watts, 1983a).

Against the backdrop of the counter-revolution in development theory and the rise of neo-liberalism globally in the past three decades, primitive accumulation has returned as a category of analysis. Much of this has been spurred by the new ways in which various sorts of commons – common property resources, the airwaves, human and plant genetic materials – have been subject to the violent forces of privatization and what Marx called ‘dispossession’. Massimo De Angelis and the electronic journal The Commoner have been especially important in rethinking primitive accumulation in the context of globalization and neo-liberal hegemony (see also RETORT, 2005). Harvey (2005) has also returned to primitive accumulation in his account of neo-liberalism. Here he draws upon the important observation made by Arendt (1958) that primitive accumulation – the ‘original sin of simple robbery’ – was repeated historically as capitalism expanded into non-commodified areas, sectors, countries and frontiers. Harvey deploys this insight to show that neo-liberalism has typically operated in global terms, especially under the auspices of American empire, as a form of dispossession – what he calls accumulation by dispossession – rather than intensive accumulation. The forms of dispossession are enormously varied – privatizing public housing, raiding pension funds, displacing indigenous people through dam projects, privatizing germ plasm – and throw up quite varied forms of resistance, typically articulated around the defence of the commons, which have been a fundamental force in the so-called anti-globalization movements.

In the socialist arena, a notion of primitive socialist accumulation was developed by Preobrazhensky in the 1920s, in post-revolutionary Russia (see Preobrazhensky, 1965). He emphasized that maintaining the equilibrium between the market share of industrial and agricultural output at pre-war levels meant upsetting the balance between rural effective demand and the commodity output of the town. A large increase in heavy investment was required that could not be funded internally; hence agriculture had to bear the burden. State trading monopolies would divert excess demand from the peasantry to investment from consumption. This was to be achieved by a sort of unequal exchange in which agrarian goods were underpriced and manufactures overpriced. This monopoly pricing by the state – in effect, a massive tax on peasants to kick-start heavy industry – was the socialist model of primitive (original) accumulation. The presumption was that the terms of trade would strike the kulaks hardest. A brilliant theorist of socialist accumulation, he broke with both Trotsky and Stalin and was arrested and shot in the late 1930s. MW

De Angelis (2006).

primitivism A Euro-American discourse that represents the indigenous cultures of sub-Saharan Africa, South America and the Pacific islands as outside the perimeter of civilization. It was inspired by European travel-writing, and in particular by the discoveries made by European explorers in the South Pacific in the closing decades of the eighteenth century. Its imaginative geographies received formal expression in post-enlightenment philosophy (Rousseau’s ‘noble savage’), in modern art (Gauguin’s Tahiti), and in early anthropology (Malinowski’s Argonauts of the Western Pacific). In all three cases, the possessive is significant: while primitivism was often connected to a critique of modernity (a ‘oneness’ with nature, for example, an intrinsic simplicity, and a celebration of the sensual and the spiritual through the fantastic), it was also closely tied to colonialism. In many ways, it acted as the cultural dual to the concept of tropicality, and is a powerful reminder that colonial discourse was about more than orientalism. Historically, ‘primitivism has its place in the genealogy of relationships between the West and the Other: it allows one to grasp the geography by which the West has constructed itself in reference and opposition to “Elsewheres”. Conversely, primitivism accounts for the geography of these “Elsewheres”, in that they were transformed, and even produced by the West’ (Staszak, 2004, p. 362). But primitivism continues to
The first figure in each cell indicates Suspect A’s punishment if that option is chosen by them both, and the second indicates Suspect’s B punishment. Thus if neither confesses to the robbery, each serves one year in prison; if A confesses and B does not, however, then A will be freed and B will serve ten years. For each, the best option is to confess, because if either remains silent and the other confesses, he will get ten years’ imprisonment. Neither dare stay silent for fear that the other will not. If the two could collude, or could guarantee that the accomplice would stay silent, then the optimal solution is for both to remain silent – a one-year sentence. But because neither can guarantee the other’s choice, each selects a sub-optimal outcome and gets an eight-year sentence.

The dilemma has been used as a metaphor not only to illustrate that selfish behaviour may not be in an individual’s best interests, but also that it is not in a person’s interests to act unselfishly if everybody else takes the selfish option, particularly in issues regarding resource use and resource management (cf. Tragedy of the Commons). In most situations involving more than a small number of actors, it is argued, unselfish behaviour can only be guaranteed if enforced by an external authority, such as the state, which exists to promote both the collective and the individual good – although there are many situations (some illustrated by more complex versions of the prisoner’s dilemma game – such as the iterated prisoner’s dilemma, in which the ‘game’ is played many times: see Axelrod, 1984) in which co-operation is sensible and can promote the collective good without state involvement.

prisons Segregative institutions designed to punish, typically for criminal offences. Prisons are usually strictly regulated and tightly surveyed environments, to which offenders are confined for varying lengths of time, and sometimes for life. Often referred to as ‘penitentiaries’ or ‘correctional institutions’,
prisons may also seek to reform inmates to reduce the possibility of re-offending. Although confinement is central to all prisons, incarcerative institutions vary in the types of offenders they house and the degree of security that they ensure.

The geographical literature on prisons is scant, despite the manifold geographical conditions and consequences of practices of incarceration. Imprisonment is essentially a territorialized form of punishment, a banishment from social life. In this way, it is an extreme manifestation of the territorial power of the state. Prisons can also be considered in terms of their own internal geographies, the ways in which they are constructed to maximize surveillance and control, a process colourfully and famously outlined by Foucault (1995 [1975]). These geographies, in turn, structure a particular social order, a ‘society of captives’ (Sykes, 1958), who adapt to prison life and its various dangers. Prisons typically contain different levels of confinement, such that those who are viewed as especially problematic inmates can be isolated in solitary conditions. Increasingly, whole institutions – so-called ‘super maximum security’ (or ‘supermax’) prisons – are dedicated to housing those violent criminals presumed to be habitual offenders in conditions of extreme isolation (Rhodes, 2004).

More macro-oriented analyses see prisons as reflective of wider social patterns, such as economic dynamics. Since 1980, the number of people imprisoned in the USA has increased by more than 450 per cent, and Gilmore (1998, 2007) attributes this extraordinary expansion to the production of disposable or ‘surplus’ populations under the signs of an aggressive militarism and neo-liberalism. She traces the formation of an American prison–industrial complex to state-sponsored prison construction in declining rural areas and the outsourcing and privatization of incarceration.

Prison populations can also be analysed in terms of their demographic characteristics. That prisons are commonly occupied by poor people of colour is suggestive of wider patterns of social differentiation and spatial exclusion: incarceration can thus be understood as yet another manifestation of racialized discrimination (see RACISM). The experience of incarceration works to increase these social divisions further still, because those convicted of crimes often face significant odds in returning to the economic mainstream. These negative consequences of incarceration can affect entire neighbourhoods where ex-convicts cluster, and further reinforce wider social and economic divisions between different spaces within a metropolitan area (Fagan, 2004).

Prisons are also a key component of wider carceral geographies. These geographies promise to enlarge as concerns about terrorism intensify. Sites such as Guantanamo Bay are part of a carceral archipelago, a ‘global war prison’, used to further the ‘war on terror’ (Gregory, 2007). Indeed, the logic of imprisonment is arguably extended to other terrains – such as Gaza, often described as an extended ‘open-air prison’ – to monitor and control those deemed hostile to the particular interests of a state.

**private and public spheres** Discursively constructed, contested categories that define boundaries between households, market economies, the state and political participation. The concepts are central to two distinctive, yet intertwined, discussions of the public sphere, and ideologies and practices of separate spheres.

Jürgen Habermas’ account of the bourgeois public sphere has been particularly influential (see Capitalism; Critical Theory). He argued that early capitalist societies were organized into four institutional spheres: family-consumer (private), market economy (private), the state (public) and citizen-political participation (public) – the last he identifies as the bourgeois public sphere. As both a historical phenomena and normative ideal, the bourgeois public sphere functioned as a counterweight to the state; it was where ‘the public’ was organized and represented, and served to mediate the relations between the State and society. This liberal model of the public sphere (see Liberalism) was never fully achieved, he argued, but became less attainable in welfare state capitalist societies, in which the separation between the state and economy, public and private, was dissolved, and family-consumer and citizen roles were transformed. The role of citizen assumed new forms (see Citizenship): of passive recipient of publicity and social welfare client. Habermas’ account is suggestive to geographers: he analyses landscape changes that concretize and reinforce both the rise and decline in active public debate (e.g. coffee houses and nineteenth-century urban culture, and the suburb, respectively: Habermas, 1989 [1962]). His account of the ideal of the
bourgeois public sphere is nonetheless widely criticized for universalizing a model that arose within exclusionary (male, bourgeois, white) spaces in historically specific European societies (Howell, 1993; Mitchell, 2003a). Feminists have argued that gender exclusions are constitutive (and not simply incidental to) Habermas’s idealization of the bourgeois public sphere (Fraser, 1997), and that he unwittingly reproduces a separate-spheres ideology that has been the focus of so much feminist criticism and organizing (see feminism; feminist geographies). This is an ideology that renders domestic space as the repository of the emotions and private interest, and women ‘by nature, guardians of the “household of emotions” . . . a kind of sphere within [the private] sphere’ (Marston, 1990, p. 456).

A notion of public sphere is nonetheless central to democratic theory and practice (see radical democracy), and there have been numerous, including important feminist, attempts to rethink it in contemporary contexts. Fraser (1997) does this by questioning four of Habermas’ assumptions, including the liberal assumptions that private interests are antagonistic to the public sphere, and that one cohesive public sphere is the ideal. She argues for a theory of multiple, contending, sometimes mutually exclusive public spheres. This questioning and retheorization reflects a feminist understanding that what counts as private and public is itself the result of political struggle, and a scepticism about the ways in which concepts of ‘privacy’ and ‘the private’ often protect dominant (male) interests by depoliticizing a range of issues (such as spousal assault and child care) and legitimating the oppression of women.

Feminist retheorizing of multiple public spheres tends to emphasize the many ways in which a separate-spheres ideology continues to haunt dominant public spheres, and the persistent traffic between constructions of public and private. Fraser (1989) has described how the US state has installed a separate-spheres ideology within systems of social welfare provision, so that women are often positioned as dependents and men as deserving bearers of rights. In her analysis of a powerful coalition of women’s organizations advocating the rights of women to public safety in northern Mexico, Wright (2005) notes that activists in these organizations ‘face the paradox that by exercising their democratic voices through public protest, they are dismissed, by their detractors, as “unfit” citizens, based on their contamination as “public women”’ (p. 279). And though they can challenge this ‘twisted logic’, ‘they cannot fully escape its implications’ (p. 279). Berlant argues that in the USA over the past 25 years, the public sphere has collapsed into the intimate, such that ‘the family sphere [is] considered the moral, ethical, and political horizon of national and political interest’ (1997, p. 262).

Geographers have sought to theorize the relations between the public sphere(s) and public space. There is a reticence simply to layer the terms on to each other, in part because much political organizing, especially for non-dominant groups, takes place in so-called private spaces, and thus there is a need to expand our thinking about the spaces of politics (or the public sphere) (Staeheli, 1996). Nevertheless, public spheres and public spaces are linked. The regulation of public space is instrumental in regulating public debate and excluding some groups from public life, and ‘public spaces are decisive, for it is here that the desires and needs of individuals and groups can be seen, and therefore recognized, resisted, or . . . wiped out’ (Mitchell, 2003, p. 33). The distinction between spheres and spaces preserves the understanding that the concept of public sphere is in large part a democratic ideal that we strive towards, in and through the construction and use of public space. It is an ideal that can be redeployed by those who are excluded from actual political spaces – to demand inclusion within them. For this reason, some theorists have been drawn to the metaphor of ‘empty space’ to articulate the inevitably unfulfilled promise of a democratic public sphere (Pratt, 2004).

private interest developments (pids)
Communal housing projects in the USA (also known as community interest developments and common interest communities), in which the property is held in common and its use governed by a homeowners’ association. Those associations – many of which have considerable power over what can be done within the development – operate as ‘private governments’ separate from the state apparatus, although their decisions can be challenged legally. Originally associated with condominiums, the pid form of governance has spread to other housing types, covering more than 10 per cent of all US housing and a much
higher proportion of all new housing. Most pid residents are relatively affluent, using a TERRITORIALITY strategy to distance themselves from perceived NEGATIVE EXTERNALITIES.

Privatization An increase in private ownership, control and action relative to public ownership, control and action. This may occur in three main ways. Assets and activities can be transferred from the public sector to the private sector (e.g. when a state-owned company is sold to private shareholders or the cleaning of a public building is contracted-out to a private company); private interests can increase their influence in the public sphere (e.g. when private retailers are given greater control over the uses of PUBLIC SPACE outside their shops); or private provision may grow faster than public provision (e.g. if more private than public housing is built in an area, the local housing stock becomes relatively more privatized). Privatization is often understood as one element of the rise of neo-liberal POLITICAL ECONOMY (see NEO-LIBERALISM).

Privatization has been prominent in many countries since the 1980s. Three major drivers of privatization can be identified. The rise of New Right politics during the 1980s in several Western countries (notably the USA under the Reagan administration and the UK under the government of Margaret Thatcher) was associated with economic policies that emphasized MARKET solutions and the rolling back of the STATE. This led to major sales of public assets (from utility companies to housing) and an expansion of private provision of services through contracting out and competitive tendering. A second phase of privatization was associated with the STRUCTURAL ADJUSTMENT programmes require by the INTERNATIONAL MONETARY FUND as a condition of much of its lending to low-income countries. The third driver has been the collapse of state SOCIALISM and the reintroduction of capitalist relations of production in former state socialist countries (cf. POST-SOCIALISM).

Geographers’ interests in privatization focus on the unevenness of the process and its outcomes within and between countries, on the effect of privatization in generating wider processes of socio-spatial RESTRUCTURING, on its implications for understandings of state SPATIALITIES and on the privatization of space itself, through the growth of such things as semi-private shopping malls and urban GATED COMMUNITIES, and the sale of public land to private developers.

A binary view of privatization as a straight switch from public to private may be oversimplified. It risks neglecting the role of the ‘third sector’ of voluntary organizations, NGOs, civic associations and the social economy, which are neither wholly public nor narrowly private. In addition, marketization – the introduction of internal trading and quasi-MARKETS in the public sector, reductions in state subsidies to the private sector and the growth of user charges for public services – blurs the boundary between the public and the private, as does the widespread use of public–private partnerships in the GOVERNANCE of social and economic development.

Privatization has been an important source of capital ACCUMULATION and corporate profitability since the 1980s, but it has also been the target of major political protests. The privatization of WATER distribution in low-income countries has been of particular concern to protestors, because of the negative effect of charges on poor households’ access to clean water.

Probabilism A thesis about the relationship between CULTURE and NATURE, which proposes that while the physical environment does not determine how human societies will react to its influence, it renders some responses more likely or probable than others. Probabilism thus aims to occupy a philosophical position somewhere between ENVIRONMENTAL DETERMINISM and POSSIBILISM. While debates over this issue were most characteristic of late-nineteenth- and early-twentieth-century GEOGRAPHY, recent reassertions about the power of the environment to channel human history in certain directions – such as those of Jared Diamond (1987) – have reopened aspects of the debate in some quarters (for a critique, see Judkins, Smith and Keys, 2008: cf. CULTURAL ECOLOGY; POLITICAL ECOLOGY). Despite its abstract clarity, in historical terms probabilism was perfectly compatible with the possibilist geographies associated with the French School of HUMAN GEOGRAPHY led by Paul Vidal de la Blache (see Lukermann, 1965).

Spate (1968).
**probability map** A probability map displays the estimated likelihood that a pre-defined event will occur at a specific point or defined area within a geographical space, during a particular period of time. For example, probability maps are used in meteorology to show the likelihoods of above-normal rainfall occurring around the globe (see, for example, the UK Met Office’s seasonal forecasts at www.metoffice.com/research/). To interpret probability maps, it is important to know how the probabilities were calculated and interpolated across the map space, and the period for which the event is predicted (a 33 per cent chance of annual flooding being worse than a 33 per cent chance of decennial flooding).

**process** A flow of events or actions that produces, reproduces or transforms a system or structure.

It was not until the 1960s that modern geography was alerted to the complexity of the concept of a process. Blaut (1961) insisted that the standard distinction between *spatial structure* and temporal process derived from a KANTIANISM that had been discredited by what he called ‘the relativistic revolution’. It was now clear, so he claimed, that ‘nothing in the physical world is purely spatial or temporal; everything is process’. In Blaut’s view, therefore, ‘structures of the real world’ that seemed to have a fixity and permanence were simply ‘slow processes of long duration’. In principle, most formalizations of *spatial science* appeared to accept this claim – Golledge and Amedeo (1968) and Harvey (1969, pp. 419–32) gave ‘process laws’ a central place in their *models of explanation* in geography (see POSITIVISM) – but in practice many studies simply used distance as a surrogate for process (hence ‘spatial processes’) and thus confirmed the geometric cast of LOCATIONAL ANALYSIS and SPATIAL ANALYSIS as these were conceived at the time (see DISTANCE DECAY).

Many of these locational–spatial models depended on *formal language systems*; that is, language systems whose elements have unassigned meanings. The xs and ys in their equations or the points and lines in their diagrams could refer to anything – they were empty of concrete content – and so analysis was governed by the relations between these abstract elements in the language system itself: by (say) the theorems of geometry, the calculus of probability theory or the mathematical theory of STOCHASTIC PROCESSES, rather than by what Olsson (1974) called ‘the things we are talking about’. These locational–spatial models of spatial process were reviewed in Cliff and Ord (1981).

Subsequently, however, there was a turn towards human geographies based on ordinary language systems whose elements have assigned meanings. This allowed more substantive conceptions of process to be utilized in human geography: cultural processes, ecological processes, economic processes, political processes, social processes and so on. Early examples included a focus on cognitive and DECISION-MAKING processes in BEHAVIOURAL GEOGRAPHY, on the dynamics of the LABOUR PROCESS and cycles of capital ACCUMULATION in ECONOMIC GEOGRAPHY, and on practices of social and symbolic interaction in CULTURAL GEOGRAPHY and SOCIAL GEOGRAPHY. This in turn, and of necessity, opened up a sustained dialogue with the other HUMANITIES and social sciences. For, as Harvey (1973) recognized, ‘an understanding of space in all its complexity depends upon an appreciation of social processes [and] an understanding of the social process in all its complexity depends upon an appreciation of spatial form’. One of his most pressing concerns was thus to ‘heal the breach’ between the sociological and GEOGRAPHICAL IMAGINATION.

The distinction between ‘formal’ and ‘substantive’ definitions of process was cross-cut by a second distinction drawn by Hay and Johnston (1983), between ‘sequences’ and ‘mechanisms’:

1. **Process as sequence in time and/or space.** This view of process is characteristic of the VERTICAL THEMES of traditional HISTORICAL GEOGRAPHY and of mathematical–statistical SPACE–TIME forecasting models. In both cases, the account is morphological and descriptive: compare Darby’s (1951) identification of the processes that changed the English landscape (‘clearing the wood’, ‘draining the marsh’ etc.) with Bennett’s simple (1979) typology of barrier, hierarchy, network and contiguity processes.

2. **Process as mechanism.** This view of process is characteristic of both SYSTEMS analysis in geography and of geographies conducted under the sign of REALISM (which require the identification of the relations between the ‘causal powers’ of structures and the conditions under which they are realized). In both cases the account is interactive and explanatory: it seeks to show how – by what means, through which networks – particular outcomes materialize.
Hay and Johnston (1983) insisted that it was possible (and necessary) to reconcile these two approaches. Since their objective was also to use quantitative methods to analyse spatio-temporal sequences and networks of connection and consequence, they were also seeking to employ formal language systems to substantive effect.

Through the 1980s and 1990s, most human geographers resisted such ecumenical attempts to integrate these different conceptions of process, however, and the dominant approaches focussed on describing processes through ordinary language systems and conceptualizing them as mechanisms. ‘Mechanism’ was soon replaced by more fluid metaphors, a sharper sense of agency, and a greater historical sensibility (see, e.g., structuration theory). The most common focus was on power and practice and on the capacity of various forms of socio-spatial theory to elucidate their operation and outcome (see, e.g., Pred, 1984). More recently still, there has been a return to the sort of (non-Kantian) philosophical reflection recommended by Blaut forty years earlier, as a way of reworking these understandings of place, power and, crucially, practice. Much of this effort has been directed towards the elaboration of a relational philosophy in which ‘process’ takes centre stage, but in startlingly different guises. Thus Harvey (1966) turned to G.W. Leibniz (1646–1716) and A.N. Whitehead (1861–1947) to guide his theorizations of a dialectical space–time (Sheppard, 2006) and co-productions of space and nature (Braun, 2006). Thrift (1999) and his collaborators turned to a dazzling array of European philosophers, including Ludwig Wittgenstein (1889–1951), Martin Heidegger (1889–1976), Maurice Merleau-Ponty (1908–61), and Gilles Deleuze (1925–95) and Félix Guattari (1930–92), to address similar themes, but in ways that animate an altogether different politics. Thrift’s non-representational theory involves an attempt to rethink our most basic ontology as a means of coping with an always becoming world of contingency, change and emergence (through what Thrift (2006, p. 140) calls a ‘processual sensualism’); to invoke radically different conceptions of time as well as space as a means of sensing the multiple elements that flicker into being in networks of places; and to incorporate performance and performativity as a means of grasping the precarious, conditional and always consequential achievements of ‘world-making’ and ‘geo-graphing’ (Thrift, 1999).

There are substantial disagreements between these materialisms, but they share a view of human geography as incomplete project and unmastered process.

**producer services** Services provided as inputs into the production process. This is in contrast to those services – consumer services – that are supplied to individuals or ‘end’ consumers, such as other firms or governments. Producer services are often characterized as intermediate inputs, before the product is completed. They include a diverse set of economic activities, such as accountancy, advertising, finance, marketing and research and development. It was in the late 1970s that geographers first became aware of the growing contribution that this type of economic activity was beginning to play towards economic growth (Dicken, 2006). Work on producer services became important in economic geography in the 1980s and early 1990s in its own right (Daniels, 1993), as well as being the basis for research into the emergence and classification of global cities.

The research in the geographically uneven development of producer services has revealed how and why they have important economic consequences (Bryson, Daniels and Warf, 2004). First, the supply and the demand for these services need not take place in the same place. Adverts can be produced or supplied in one place, and then e-mailed elsewhere, to the end consumer, from where there is demand. Second, and stemming from this spatial disjunction between supply and demand, producer services are only partially dependent on the level of economic activity in their cities and regions. Clusters of interconnected activity – around, for example, advertising in London (Grabher, 2001) – raise the city’s profile but are not reliant on selling the product, in this case the advert, in London. Rather, the producer service is sold all over the world. The economic development to be wrung out of expanding producer services has been noted by policy-makers and politicians, and the sectors have found themselves important elements in the formation of urban and regional policy.

**product life cycle** A concept used to connect the evolution of a product to changes in the
location of its production (cf. PROFIT CYCLE). The idea is usually attributed to Vernon (1966), although its antecedents are considerably older. Vernon intended his model as an alternative to the Heckscher–Ohlin model of international TRADE, and he insisted that INTERNATIONAL INVESTMENT decisions taken by manufacturers were driven by more complex considerations than differences in factor and TRANSPORT COSTS. He proposed instead that products evolve through three distinct stages, and that manufacturers choose different locations in each of them:

(1) The new product tends to be unstable, since its design and production are still being modified and perfected. This usually involves considerable interaction between producers and suppliers and between producers and consumers as modifications are introduced, test-marketed and appraised. Producers thus require swift and effective access to a deep and diverse pool of suppliers and to consumers. These requirements are most likely to be met in major metropolitan industrialized economies.

(2) The maturing product undergoes a process of increasing standardization and, as market demand grows, the scale of production increases. Uncertainties about design and marketability diminish, so the need for flexibility is reduced. The major concern for most manufacturers becomes minimizing production costs, and they seek locations outside the most heavily industrialized economies, where labour costs are lower.

(3) The standardized product prompts manufacturers to turn still further afield, to less developed countries, particularly where their products are labour-intensive, have a high price elasticity of demand, and are only weakly dependent on EXTERNAL ECONOMIES for their production.

Although these ideas were directed at international trade, they enjoyed their most intensive application at the sub-national SCALE. Thompson (1968) recast Vernon’s hypothesis as a ‘filtering-down’ theory of urban economic change. New products were supposed to originate at the top of the urban hierarchy because of the concentration of highly educated scientific and technical workers, universities and other research institutions. The earliest production of such INNOVATIONS would occur in the same REGIONS for the reasons outlined by Vernon. With increasing standardization of the product and production process, the tie to such highly skilled labour would weaken, and cost considerations would drive manufacturers to seek out locations in intermediate urban centres where semi- and unskilled workers would be available in large numbers at lower wage rates. As products reached advanced maturity, their production would shift to the lowest tiers of the urban hierarchy or out into rural locations. Thompson’s assessment of the long-term prospects for such regions was unequivocal: ‘their industrial catches come to them only to die’ (p. 56). When Vernon and Thompson began to work on the product life cycle concept, the long-term dominance of established industrial regions such as the Manufacturing Belt of the USA was unchallenged. For Thompson, the decline of such regions was unthinkable, because of their proven ability over the long run to continue to generate new products. The loss of manufacturing to more peripheral regions through the filter-down process was thus little cause for concern. A scant decade later, however, these assumptions were called into question by a major shift in economic activity between the regions of the USA. For Rees (1979) and Thomas (1980), the decline of the Manufacturing Belt could be explained by the accelerated rate of DECENTRALIZATION of production activities, as intensified competition from newly industrializing countries heightened the importance of cost-reduction for US-based manufacturers. And in contrast to Thompson’s views, Rees and Stafford (1986) argued that previously peripheral areas such as the US Southeast could eventually achieve a critical mass once a sufficient volume of capital had been invested in production facilities in the region. At this point, they suggested, the ‘incubator’ functions generating new products and firms traditionally associated exclusively with the largest metropolitan regions in the Northeast and Midwest could take root in these new locations. This thesis found empirical support in studies showing that many of the largest manufacturing firms had already shifted some of their highest-order (especially research and development) functions away from their original headquarters locations to places further down the urban hierarchy (Pred, 1977: see also SUNBELT/SNOWBELT).

More recently, the product life cycle concept has been criticized for its excessive determinism and ESSENTIALISM, especially its implicit claim that all products follow a similar trajectory over time (Storper, 1985; Taylor,
1986). Critics have pointed out that even standardized and mature products can be rejuvenated through innovation in the later stages of a product’s life cycle. A case in point is the automobile which, while hardly a new product, has been continuously modified and improved over time. It has also been argued that many commodities never achieve the status of cheap, standardized, mass-produced goods – especially those that, under a regime of post-fordism, exhibit a high degree of variability, customization and qualitative differentiation.

**Suggested reading**

**production complex** A spatial cluster of specialized, interrelated economic activities bound together by the creation and exploitation of external economies (Scott, 1988b). Such clusters offer producers the ability to establish, and easily realign, transactional linkages with other local buyers and suppliers, thereby encouraging the development and maintenance of a social division of labour (see just-in-time production; transaction costs; transactional analysis). They also provide a local labour market specialized to match the needs of local producers. They are further sustained by the existence of public and quasi-public institutions developed to support specialized local economic activity and to foster non-market forms of interaction and interdependencies between local economic actors. (See agglomeration; commodity chain/filière; industrial district.)

**production of nature** This rather strikingly counter-intuitive phrase comes from Neil Smith, originally in his book Uneven development (1984). Despite its critics, perhaps nothing attests to the power of the idea more than the fact that the phrase becomes less counter-intuitive with time.

At the simplest level, and clearly influenced by Lefebvre’s understanding of the production of space, Smith conveys by this phrase that nature is socially produced and, more specifically, that nature is increasingly an artefact of capitalism in the contemporary world. At one level, this is not so counter-intuitive at all. Increasingly, at scales from the atmospheric to the genetic, the material natures of everyday life are increasingly transformed either by intentional manipulation for the purposes of commodity production (e.g. genetically modified crops), or by the myriad ecological impacts of industrial, capitalist activities and related processes (e.g. the deposition of persistent organic pollutants in Arctic and Antarctic ecosystems). Since Smith’s book, empirical processes that confirm the material production of nature to suit economic purposes have proliferated, including the onset of commercial aquaculture and the continued globalization of plantation forestry. Moreover, empirical research has elaborated Smith’s thesis, indicating that the capitalist production of nature, often in shifting and complex institutional configurations, has been ongoing for some time (Prudham, 2003). While agriculture would be the most obvious example to draw on here, under which the intentional transformation of crops and animals is probably in excess of 10,000 years old, Smith is at pains to differentiate the capitalist production of nature from all that has come before it. This is not, as he argues, because widespread anthropogenic change is unique to capitalism (quite the opposite). Rather, it is because the particular ways that nature is transformed under capitalism are unique. This includes, for instance, the appropriation and transformation of biophysical processes as a constitutive facet of uneven development under capitalism. An elaboration of this, with some qualification, can be found in Robbins and Fraser (2003), who note ‘... if the state can put non-commercial Scots pine woodland in the place of industrial forests, it is only, after all, because increased extraction is occurring in the Baltic states, Indonesia, and Ghana ...’ (p. 113). Here, produced nature is worked through as a complex set of spatial and scalar logics that link far-flung places, not least through market relations and exchange, as well as in the realm of production per se.

However, Smith’s thesis is not only about the material transformation of nature under capitalism. Rather, he also posits that a unique feature of what might be called ‘capitalist nature’ is the ways in which ideas about nature are also produced in and through capitalist production, commodity circulation, and capitalist social relations and institutions. This is a complex and controversial thesis. Yet, at one level, Smith’s observation is no different than those who have long recognized the rise of instrumental, utilitarian thinking alongside industrial capitalism. Smith’s argument is that such an instrumentalist disposition specifically towards nature is reinforced by capitalist social relations and processes of valuation, and that these ideas become increasingly influential in the construction of meaning around nature in...
a capitalist society. Examples would include instrumental, utilitarian arguments for biodiversity conservation, which tend to both render species in terms of net present value of future benefits, while also individuating such species in relation to their ecological (and social!) context. A key facet of Smith’s thesis in this respect is his anticipation of social construction debates within critical environmental geography, but his mobilization of specifically capitalist ideologies as decisive influences on how nature comes to be known (constructed).

The production of nature thesis, despite being influential and widely cited in critical environmental geography, has arguably not been sufficiently developed or elaborated since its first publication. An exception is Castree (1995), who argues (sympathetically) that the thesis may reinforce Promethean discourses by downplaying the productive capacity of biophysical processes. Here, there is room for some sort of rapprochement with the hybridity literature (e.g. Whatmore, 2002a), which emphasizes the epistemological and ontological co-production of nature by human and non-human alike. Another avenue not well travelled would explore the links between Smith’s thesis and James O’Connor’s second contradiction of capitalism (O’Connor, 1998). While O’Connor would quibble little with the notion of capitalism producing nature in this respect (it also comprises part of his theory), he places greater emphasis on this as a source of contradiction and crisis inherent to capitalism because of the under-production of nature as a condition of social reproduction. SP

production of space  A term made famous by French Marxist Henri Lefebvre (1901–91) in his 1974 book The production of space (trans. 1991). Lefebvre seeks to bring a Marxist analysis of production to bear on the way space is created, coded and used through social, political and everyday processes (cf. production of nature). Social space is, for Lefebvre, a social product. Lefebvre came to the analysis of space through three main routes: his reworking of the philosophy of Marxism and in particular the notion of the dialectic; work supplementing Marxist political economy, with an experiential emphasis on everyday life; and work on rural and urban sociology. Lefebvre was in his early seventies when The production of space was published, and had been publishing for almost 50 years: this mature work is one of the culminations of these varied interests and concerns (for overviews, see Kofman and Lebas, 1996; Shields, 1999; Elden, 2004; Merrifield, 2006).

In the opening chapter of The production of space, Lefebvre suggests that we should understand space in three ways – as perceived, conceived and lived. The first of these, what he calls spatial practices, are spaces that are concrete, material, physical. The second is what he calls representations of space, the space of abstract plans and mental processes. Both of these ways of thinking about space are relatively common within human geography, but it is with the third that Lefebvre makes his key contribution. Lefebvre claims that both these spaces need to be thought together, in dialectical relation. But this is not a linear sense of the dialectic, in which the two terms react and form a new term that then itself comes into relation with its opposite. Rather, this is a dialectic where the third term continues to exist in relation with the other two (cf. trialectics). Lefebvre’s third term here is what he calls spaces of representation – confusingly rendered as ‘representational spaces’ in the English translation – spaces that are lived, experienced and recoded through the actions of those that occupy and use them. Lefebvre therefore challenges both a crudely materialist analysis and a politically detached idealist one. For Edward Soja, whose reading of Lefebvre has been influential in Anglophone human geography, in contrast to the ‘real’ or ‘imagined’ spaces of the other two models, these are ‘real-and-imagined’ spaces, which he has deployed himself in readings of Los Angeles and in his construction of third space (Soja, 1989, 1996).

In the remainder of The production of space, which is a complex work that defies straightforward summary, Lefebvre returns to this three-part model and illustrates, complicates and historicizes it. His is an analysis in the tradition of historical materialism, and the spaces of a particular epoch are related, though not slavishly dependent on, the mode of production (see figure 1) (for a summary, see Gregory, 1994, who also emphasizes Lefebvre’s suggestive reading of the changing historical modalities of the body, visibility and space). Thus capitalism produces a particular political economy of space, centrally defined through the ‘colonization of everyday life’ through the production of abstract space (see figure 2), which Lefebvre sought to develop into a politics of space. As he declared in a 1970 essay, ‘there is a politics of space because space is political’. Lefebvre was indebted to a range of thinkers who he used
production of space 1: The production of space (Gregory, 1993; after Lefebvre)
to supplement Marx—notably G.W.F. Hegel, Friedrich Nietzsche and, more critically, Martin Heidegger. Each of these thinkers was useful, Lefebvre contended, in adding things that Marx’s analyses alone could not provide. Marx was the indispensable starting point for Lefebvre at each stage of his career, but Heidegger was particularly useful in thinking about the question of space. Heidegger’s analysis of how modern thought’s mathematical, geometrical sense of space is reductive and we need to recall how to dwell or live is crucial to Lefebvre’s thinking through of the alienating properties of capitalist space, particularly in the city (cf. alienation).

Lefebvre’s work has come under sustained criticism from more orthodox Marxists, for whom his emphasis on space trembles on the edges of or, more directly, simply is a form of spatial fetishism. In fact, these criticisms, and other engagements with his writings, by scholars such as Manuel Castells, David Harvey and Neil Smith, were available in English before Lefebvre’s work was translated, and it was left to later commentators to explore quite other dimensions of his work. The utilization of thinkers such as Heidegger and Nietzsche brought Lefebvre into a tense proximity with the post-structuralism of thinkers such as Michel Foucault, but Lefebvre was strongly critical of their anti-humanism and their use of spatial metaphors in the absence of more concrete analyses (cf. Gregory, 1997b). It has largely been left to Anglophone geographers such as Soja (1989, 1996), Gregory (1994) and Dear (1997) to develop the commonalities and complementarities of their approaches (see also Gunewardena, Kipfer, Milgrom and Schmid, 2008).

Although The production of space remains his most influential work in human geography, Lefebvre’s writings on cities (e.g. 1996), everyday life and Marxist theory are also available in English translation and provide much useful material. Lefebvre is commonly looked at as a theorist of space, yet he would have equally stressed his work on time and temporality (Lefebvre, 2004 [1992]: see rhythmanalysis), suggesting that space and time need to be rethought, and thought together, in any genuinely radical political action. **Suggested reading**

**productivity** A measure of output relative to input, usually expressed as the ratio of the returns from sales to the costs of production. The term was developed in analyses of the efficiency of manufacturing industry, where it is equivalent to the rate of surplus value or rate of exploitation in Marxist economics.
The higher the amount of value-added in the production process relative to the costs incurred (of labour, materials and fixed capital), the greater is the productivity. In primary industries, however, productivity usually implies the ratio of production per unit area of land rather than to its (imputed) cost.

With the growth of service industries in advanced capitalist societies, attempts have been made to measure productivity in sectors other than manufacturing – not least in higher education! – though the concept of value added is not readily applied in many such situations.

profit cycle A sectoral approach to understanding changes experienced by regional economies, developed by economist Ann Markusen as an alternative to the product life cycle model. Instead of focusing on regularities in the changing scale of output or changes in the qualitative characteristics of a product and its production process over time, Markusen (1985) argued that the economic variable most crucial to determining industrial change is the rate of profit. Drawing her inspiration from both Marx and Schumpeter, she argued that change within an industry should be understood in terms of two central processes, each of which is pursued by firms to increase market power and hence profit rates: (i) innovation and (ii) imperfect competition. She proposed a five-stage model through which industries move:

- New industries are born and core products are being designed: a regime of zero profits.
- Once an innovation is commercially successful, and so long as its production is concentrated in the hands of a single (monopoly) firm, super profits are likely.
- As patents expire and/or imitation and innovation diffusion facilitates entry by new firms, the market power once held by the monopoly firm dissipates. Profits decline to normal profit levels as the industry moves towards market saturation. It is only at this stage that conditions resemble perfect competition.
- If some firms increase their market shares through mergers and acquisitions, this move towards oligopoly will raise profit rates to normal-plus levels. But if the industry evolves along a path of predatory pricing and excessive competition, profit rates will be squeezed to normal-minus levels.
- Once the sector matures to obsolescence, negative profits will ensue.

Markusen argues that ‘distinct spatial tendencies’ accompany each stage of a sector’s passage through the profit cycle (1985, p. 24) (see table).

The approach is a suggestive one, but it was roundly criticized by Storper (1985) for its essentialism. While he accepted that the model was one of the most effective ways to comprehend ‘multilocational, large-scale production systems and sectoral location patterns over time’, he saw it as a premature formalization and argued for a much more historically informed analysis of the dynamics of geographical industrialization.

property Relationships between persons with respect to the use or benefit of valued things. Legal scholars tend to see property rights as residing in the ‘jural relations’ between individuals, rather than in the thing itself. If I claim a property RIGHT in a thing (such as land), what is really being asserted is that I can exclude you from access to it (Macpherson, 1978a). The law of property concerns itself with the legally recognized distribution of rights, benefits and responsibilities associated with the objects of property.

Variations can occur in terms of the range of objects over which property rights are recognized, the extent of rights that are recognized and the entities that can bear such rights. These can all be construed very broadly: for example, the objects of property can include not only land (land tenure) and money, but intangibles such as names, knowledge and shares in joint-stock companies. Despite this diversity, Western liberal societies (see liberalism) tend towards a strikingly narrow view of property, summarized by Singer (2000) as the ‘ownership model’. Private property, the default category here, is viewed in largely asocial terms: The owner is assumed to hold a full bundle of property rights (alienation, use, exclusion etc.), and is expected to be motivated by self-regarding behaviour. State intervention is presumably suspect, and must be justified in relation to the prior and superior rights of the
owner. A rich corpus of writing explores and critiques various justifications for private property (Macpherson, 1978b).

This model, it has been noted, exerts a powerful imaginative hold, shaping collective understandings of the possibilities of social life, the ethics of human relations and the ordering of economic life (Blomley, 2005). In response, scholars have criticized prevailing views of property: Singer (2000), for example, characterizes the ownership model as both descriptively and normatively flawed. One central argument, variously phrased, is that property is irreclaimably social and political in its constitution and effects (Alexander, 1998). Property rights, insists Underkuffler (2003), ‘are not simply private interests with which the state neutrally coexists. Property rights ... are collective, enforced, even violent decisions about who shall enjoy the privileges and resources which this society allocates among its citizens’ (p. 146).

Given its historical development under a liberal capitalist society (see CAPITALISM), many critics have cast property rights in a negative light, pointing to the manner in which privatized property rights instrumentally and ideologically underpin CLASS rule, PATRIARCHY and COLONIALISM. However, recent years have seen an attempt to uncover the progressive potential of property – both private and collective (Blomley, 2002).

Property is a political instrument, an element in social struggle, an object of CONSUMPTION and a site for IDENTITY formation. Given its importance, it is heartening to note some interest in GEOGRAPHY in property. Blomley has sought to uncover the ways in which conflicts over INNER-CITY GENTRIFICATION frequently invoke property claims, refracted through REPRESENTATIONS of local LANDSCAPES (Blomley, 2004b; Mitchell and Staeheli, 2005). Everyday understandings of domestic and PUBLIC SPACE are also seen to entail surprisingly complex and overlapping renderings of public and private property (Blomley, 2004a). The dynamics of COLONIALISM are also shown to entail the simultaneous reworking of space and property (Forman and Kedar, 2004). Property, of course, extends beyond claims to land: Sarah Whatmore (2002a), for example, traces the intersecting geographies of landed and INTELLECTUAL PROPERTY RIGHTS.

Geographers have also expressed interest in common property: David Harvey (2003b), for example, has argued that the ENCLOSURE of the commons, rather than an episode of early capitalism, continues across the globe (see PRIMITIVE ACCUMULATION), as does political organizing in defence of common rights (GLOBAL COMMONS; PRIMITIVE ACCUMULATION).

**propinquity** A measure of nearness or proximity, usually with reference to distance, but also to time.

**prostitution** Broadly defined, prostitution refers to the exchange of sexual services for money or payment in kind. Though often socially marginalized, the prostitute has remained a central figure in geographical debates concerning both the gendering of SPACE and the spatial regulation of conduct. Notably, it is the place of women sex workers that has attracted most attention. While some accounts have been excessively voyeuristic and uncritical, work informed by FEMINIST theory has generated some insightful geographical commentaries on the regulation of female SEXUALITY and the role of space in the maintenance of HETERONORMATIVITY. Broadly speaking, these document the SPATIALITY of prostitution on at least three related SCALES. First, attention has been focused on the more-or-less enforced movement of women sex workers across international BOUNDARIES, a phenomena that appears to be growing as criminalized global networks extend their range and influence (Samarasinge, 2005). Reading these movements as indicative of gendered global inequalities, increasing stress is also being placed on the formation of a DISPORIC sex workers’ movement opposed to enforced prostitution (Doezema and Kempadoo, 1998; see SLAVERY). Second, on a national scale there has been a strong emphasis on the connections between prostitution LAWS and the particular concerns and anxieties projected on to the BODIES of prostitute women. This literature often has a strong historical dimension, tracking the moral and political debates encouraging the use of particular forms of SURVEILLANCE and BIOPower to categorize and control sex work (Howell, 2000). Finally, there is an established tradition of urban research that documents the microgeographies of sex work in RED-LIGHT DISTRICTS. One important strand of this explores the relationship between sex workers and local residents, with a particular focus on the NIMBY campaigns of displacement that are often associated with incipient GENTRIFICATION.
(Hubbard, 2004). In all cases, research suggests the gendered inequalities of sexual commerce produces a series of spaces where women's sexuality can be bought and sold by men with relative impunity, albeit that these spaces may be important in the forging of new gender identities and formations (Law, 1997). In this sense, the relative silence on forms of male sex work poses some interesting questions about gender inequalities within and without the discipline.

Hubbard (1999).

**proto-industrialization** A term proposed by economic historian Franklin Mendels (1972) to denote ‘the rapid growth of traditionally organised but market-oriented, principally rural industry’. Whilst the presence of such industries had long been recognized, Mendels presented proto-industrialization not merely as a description of (pre-)industrial organization, but also as an explanation of industrial change, arguing that it ‘preceded and prepared for’ industrialization. In emphasizing the continuities between traditional systems of domestic production and the centralized and mechanized factory system, Mendels’ thesis is central to the broader reconceptualization of industrial revolution as an evolutionary and gradual process. Two different models have been proposed, each with its own empirical and conceptual emphasis. Ecological models focus on the pre-conditions for proto-industrialization, particularly the ways in which under-employed peasant labour was drawn into industrial production. There is little consensus on the type of agrarian economy that would favour such development, with rural industries emerging in both arable areas (with seasonal unemployment) and pastoral regions (with diurnal time-budgets). In reality, much depended upon the social and institutional environment of the area, especially land holding and the type and flexibility of labour skills. Once established, it is argued that comparative advantage led to a growing division of labour between specialist industrial and agricultural regions. However, this not only makes unwarranted assumptions about individual and collective rationality, but also fails to acknowledge the importance of other variables, such as the presence of commercialized mercantile and urban networks (Stobart, 2004).

Economic models focus on the structural relationship between the peasant/artisan and the merchant/capitalist. The artisan household sought to balance production and consumption by adjusting the level of engagement in manufacture for the market, whilst the merchant collected together the products of domestic labour and consigned them to distant markets. Although mutually dependent, the interests of these two parties were inherently contradictory. When prices fell, artisans increased production to maintain household income, thus saturating the market and worsening the recession. When prices rose, artisan households could more easily satisfy their needs and production slowed, just when merchants would seek to take advantage of increased profits. This conflict is seen as being resolved through the increasing control exercised by merchants over the production process. Initially, this involved a shift from the Kaufsystem of independent artisan production to the Verlagsystem of putting out, wherein the means of production remained in the hands of the merchant, who effectively employed dependent outworkers. This was subsequently superseded by a merchant-led centralization of production into proto-factories (Kriedte, Medick and Schlumbohm, 1981).

This version of proto-industrialization as a theory of industrial change has been challenged from three very different directions. At the level of the peasant household, de Vries (1994) has argued that consumption as well as production became ever-more market oriented, increasing household specialization and growing consumption inspiring an artisan-centred ‘industrious revolution’. At a broader scale, studies of regional industrialization have emphasized that the logic of capitalism was played out differently in different places: factory production was one of a range of possibilities, which included workshop-based flexible specialization as well as hybrid factory–workshop systems (Berg, 1994). More fundamentally, others have questioned whether proto-industrialization was, indeed, a necessary stage in industrial development, arguing that the switch from organic to mineral resources was the real key to industrialization.

**psychoanalytic theory** Originating in the late nineteenth century in the work of Sigmund Freud (1986–1939), psychoanalytic theory and practice offers a distinctive way of
thinking about the human mind and of responding to psychological distress. Psychoanalysis has travelled widely from its central European origins, and has evolved into a complex, multifaceted and internally fractured body of knowledge, situated at the interface between the human and natural sciences, and between clinical practice and academic theory.

Notwithstanding critiques of its eurocentric origins, psychoanalysis has been taken up in many different cultural contexts, perhaps most notably in Latin America, but also in India, Japan and elsewhere. Its geography and spatiality have become topics for geographical study, albeit primarily within the Anglophone literature (Kingsbury, 2003; Cameron, 2006).

Along with the more general rise of psychoanalytic thinking, psychoanalytic ideas have had a pervasive influence on such arenas of life as child-rearing, education and popular culture. Within the academy, psychoanalytic theory has been taken up most extensively in the humanities and more sporadically in the social sciences, including human geography, where a distinct sub-discipline of psychoanalytic geography has shown tentative signs of formation since around the turn of the twenty-first century.

The unconscious is perhaps the most fundamental and defining idea of psychoanalysis, albeit one that has a much longer history. For Freud, only a small proportion of the human mind is knowable through rational thought. The greater part is outside conscious awareness and full of hidden dangers. It makes its presence felt in a variety of ways, including dreams, slips of the tongue, the clinical method of ‘free association’ and other actions – the motivations for which are not discernible by, and are often contrary to, conscious intent. The psychoanalytic unconscious acts as the repository for experiences, thoughts and feelings that are unacceptable to, and are repressed by, the conscious mind. The unconscious therefore exemplifies a means by which rational human agency is ‘de-centred’ in the sense of not being the driving force of human action, an idea that has been highly influential in human geography. The radical otherness, profound strangeness and disruptiveness of Freud’s concept of the unconscious is emphasized by Felicity Callard (2003) in her review of geographers’ engagements with psychoanalytic theory.

Freud developed his ideas over a period of nearly 50 years. Not surprisingly, there are shifts, tensions and ambiguities within his work. Moreover, he founded an approach taken up by many others, who have variously extended, challenged, supplemented and reworked his ideas. One of the most influential lines of differentiation within the psychoanalytic tradition lies between those theorists who attach primary importance to the psychic life generated by the instinctual drives of the human organism, including especially drives towards pleasure and towards death or annihilation, and those theorists who attach primary importance to the psychic life generated by a different kind of drive or condition of existence, namely the drive to relate to others. Among the former, the French psychoanalyst Jacques Lacan (1901–81) has been especially influential, while the latter has given rise of object relations theory and other relational approaches to psychoanalysis, developed through such theorists as Melanie Klein (1882–1960) and Donald Winnicott (1896–1971).

Human geographers have engaged with different strands of psychoanalysis for a variety of purposes. One of the earliest examples in the Anglophone literature was methodological in focus and drew as much on psychoanalytic practice as theory: Jacquelin Burgess and colleagues (Burgess, Limb and Harrison, 1988) applied ideas from group analysis (a form of psychoanalysis that focuses on the relationship between individuals and their social context) to facilitate the exploration of environmental values in focus groups. Continuing this methodological theme, others have appealed to key ideas informing psychoanalytic practices to deepen and enrich understandings of the dynamics in play within research encounters (Bondi, 2005). Yet others have drawn on approaches derived from Carl Jung’s analytic psychology to facilitate research participants to connect with unconscious childhood experience (Bingley, 2003).

Several human geographers have deployed psychoanalytic theories to develop accounts of human subjectivity and its spatial forms. In a highly influential contribution, David Sibley (1995) examines geographies of exclusion combining Melanie Klein’s object relations account of the unconscious expulsion of feared and dreaded aspects of our selves with the post-Lacanian psychoanalyst Julia Kristeva’s discussion of the fascination and horror, preoccupation and repulsion, associated with that which is expelled. Using these ideas, Sibley (1995) illuminates the profound emotional power of exclusionary processes for the different groups whose members identify
with each other and against others in ways that generate highly potent lines of demarcation. While Sibley’s (1995) account draws primarily on object relations psychoanalysis, Robert Wilton (2003) draws on Freud’s concept of castration together with Lacan’s reworking to explore how the geographical exclusion of disabled people may serve to shore up illusions of ‘ableism’ (cf. DISABILITY). Lacanian readings of Freud are also evident in geographical accounts of topics such as RACISM (Nast, 2000) and embodied experiences of cities (Pile, 1996).

A product of nineteenth-century European culture, Freud hypothesized that the repressed unconscious contains much material of a sexual nature, which would be highly disruptive if allowed to break through into consciousness. He argued that in order to grow up in socially acceptable ways, boys and girls were called upon to repress their ‘natural’, sexual (or libidinal) desires. Normative heterosexual masculinity and femininity were theorized by Freud as demanding psychical achievements. Although aspects of his theories of GENDER and sexual identity have been highly controversial, his approach has also been welcomed as a resource for challenging assumptions about what is ‘natural’, and for elaborating a theory of subjectivity as situated in a zone of about what is ‘natural’, and for elaborating a theory of subjectivity as situated in a zone of critical interplay between the ‘personal’ and the ‘cultural’. For this reason, some feminist geographers have turned to psychoanalysis in their theorizations of the interplay between gender, SEXUALITY, subjectivity and space, and to contribute to critiques of the ‘MASCULINISM’ of dominant forms of knowledge (Rose, 1996; Nast, 2000: see FEMINIST GEOGRAPHIES). Against critics who consider psychoanalysis to be an intrinsically individualistic theory and practice, these applications find inspiration from the terminology, if not always the politics, of the situationists. Much interest has been literary, involving the tracing of a longer tradition of imaginative and wayward URBAN EXPLORATION, especially in London and Paris, though writers such as William Blake, Thomas de Quincey and Charles Baudelaire, and the surrealists around André Breton (see also FLÂNEUR/FLÂNERIE). Contemporary heirs of this visionary tradition include Iain Sinclair, whose peripatetic investigations of London, especially its East End, have been much to popularize the term ‘psychogeography’ (Coverley, 2006).

Contemporary artists and urban explorers have also embraced the term in their engagements with emotional and psychic spaces, through urban interventions as well as new media (Pinder, 2005a). Recent years have further seen a proliferation of psychogeographical associations or organizations in Europe and North America, whose investigations of PLACES have typically been drawn by the marginal, hidden and forgotten, and whose networking has been facilitated by the InterNET (and documented in journals such as Transgressions, 1995–2001). As psychogeography has moved increasingly into the mainstream, much of its early radical political edge has been lost. Yet its political ambitions as well as humour and idiosyncracies are also finding new and at times challenging modes of expression.

psychogeography The ‘study of the precise laws and specific effects of the geographic environment, consciously organized or not, on the emotions and behavior of individuals’, according to Guy Debord (1981 [1955], p. 5). Psychogeography is typically traced back to this definition, and to the activities of Debord and members of the Letterist International in 1950s Paris, for whom it was a means of exploring urban spaces and EVERYDAY LIFE, and who established it as a key concern of the early SITUATIONISTS. Yet the definition’s academic tone belies its politicized and playful engagement with cities, as a way of challenging dominant representations and practices, and seeking to change urban spaces and life as part of a revolutionary project. Psychogeography combined a conscious and political analysis of urban ambiences with experiments in ludic behaviour, principally through dérives or drifts on foot, and included the construction of ‘psychogeographic maps’ that challenged the values of dominant CARTOGRAPHERIES.

The term was independently employed by geographers engaged in politically motivated versions of environmental psychology in the late 1960s, especially at Clark University in Massachusetts, including David Stea and Denis Wood (Wood, 1987). While influential on subsequent work in environmental psychology (see also MENTAL MAPS), that usage has been relatively sidelined in the recent resurgence of interest in psychogeography since the 1990s that has taken more inspiration from the terminology, if not always the politics, of the situationists. Much interest has been literary, involving the tracing of a longer tradition of imaginative and wayward URBAN EXPLORATION, especially in London and Paris, though writers such as William Blake, Thomas de Quincey and Charles Baudelaire, and the surrealists around André Breton (see also FLÂNEUR/FLÂNERIE). Contemporary heirs of this visionary tradition include Iain Sinclair, whose peripatetic investigations of London, especially its East End, have done much to popularize the term ‘psychogeography’ (Coverley, 2006).

public administration  The public administration sector comprises the different government agencies that administer, oversee and manage public programmes and that have executive, legislative or judicial authority over other institutions – such as quangos – within a given spatial unit, such as a nation-state or a region. Studies of the spatiality of public administration have explored the relationships between, on the one hand, the types of services being delivered, and, on the other, the scale of their delivery (Barlow, 1991). public choice theory  Using the techniques of neo-classical economics, public choice theory examines issues of political decision-making and of the behaviour of government. It derives from the pioneering work of Duncan Black (1958) and James Buchanan and Gordon Tullock (1962), and was conceived to study politics on the basis of economic principles. Its original proponents argue that it should be understood as a research programme rather than as a discipline, or even a sub-discipline, of economics. It contends that elected politicians and government bureaucrats make decisions on the basis of self-interest. So, the behaviour and decisions of all individuals within the political sphere is purely instrumental. Politicians enact policies in terms of ensuring re-election, the voters remain deliberately ignorant because individually they do not understand it to be in their interest to learn more, and bureaucrats – those who put decisions into practice – do whatever is necessary to keep their jobs and get promoted. All involved strive to maximize their own welfare. At each decision, politicians, voters and bureaucrats make a rational choice. Public choice theory covers a series of issues; namely, government constitutions, state bureaucracies and voting behaviour.

Within public choice theory, there are five core theoretical tensions. First, there are difficulties in aggregating individual choices and decisions to produce a collective outcome. How is it possible to produce policies on the basis of the preferences of individuals? Second, there is the range of issues that stem from the introduction of public goods and market failure. There is a tendency, stemming from their monopoly power, for governments to extend public ownership beyond that deemed efficient by the market. Third, there is the issue of political party competition. According to public choice theory, the outcome of two vote-maximizing parties is almost identical parties. Only with three political parties vying for the votes of the electorate is policy variability introduced (cf. Hotelling model). Fourth, there is the difficulty of forming and organizing interest groups due to the free-rider problem (see Game theory). Fifth, there are a number of conceptual difficulties in assuming and treating public finance as a rational exchange amongst citizens. These issues have been the subjects of much empirical and theoretical work over the past four and a half decades. As a branch of neo-classical economics, public choice theory is subject to all the standard critiques of that school and, in particular, the supposition of rational choice.

Within geography, a small number of key texts have explored the issues of public goods and market failure (Cox and Johnston, 1982) and public finance and government decentralization (Bennett, 1990).

Bennett (1990); Cox and Johnston (1982).

public finance  Human geographers have studied the spatial distribution of public-sector income and expenditure. In addition to producing and analysing spatial patterns, work has examined the mismatch between the geographies of public-sector revenue generation and expenditure (Bennett, 1990) – put another way (Bennett, 1980, p. ix): who gets what, where, and at what cost? The twin focus on spatial patterns and their consequences allows the exploration of differences between individuals and between the local governments that collect and spend the revenues (cf. collective consumption). As the needs, costs and preferences for public goods vary geographically, so a failure to attend to the spatial consequences of public finance matters to issues of social justice. Once the ‘who’ and the ‘where’ are known, it is then possible to attend to the third element to the question, ‘At what cost?’ So, for example, how might the state-led geographical redistribution of resources alleviate spatial inequality? While

Debord (1981 [1955]).
concern with how the state apparatus produces and can then address spatial inequality through its finance functions remains an area of interest of geographers, Bennett (1985) has argued that equity in the distribution of public goods is a utopia. As such, the state should reduce its provision of public goods and services—and the role of the private and of the third sector should be increased, perhaps through public–private partnerships (Pinch, 1997).

Suggested reading
Bennett (1990); Pinch (1997).

**Public geographies** Contributions to geographical knowledge that address audiences beyond the academy and seek to intervene in public debate and public policy. The formal discipline of geography has a long tradition of ‘applied’ or ‘policy relevant’ work (see Applied Geography; Relevance), but the recent interest in public geographies has been nurtured by a renewed interest in the normative—in the political and ethical dimensions of geographical enquiry—and by two further, more particular, considerations. First, there has been a recognition that geographical knowledge is produced at multiple sites inside and outside the academy, and the interest in ‘public geographies’ is thus, in part, an attempt to acknowledge the importance of those other productions and sites. This means more than an interest in ‘popular geographies’. While many geographical knowledges remain undeveloped, and are often tacit and taken-for-granted, other non-academic contributions are highly developed and explicit about their intellectual and substantive basis: see, for example, the regional reports produced by the International Crisis Group, at http://www.crisisgroup.org/home/index.cfm. Second, there has been a recognition of the importance of developing and engaging audiences outside the academy, and the interest in ‘public geographies’ is thus also, in part, an attempt to speak in less technical vocabularies and to take advantage of non-academic publishing and the development of new media (particularly the Internet) to intervene in current debates in a timely and accessible fashion. These twin rationales speak to an interest in both the changing geography of the public sphere (see Private and Public Spheres) and the critical participation of geographical knowledges in its affairs (Gregory, 2005b), and they intersect with a renewed interest in ‘public intellectuals’ (Castree, 2006b; Ward, 2007). Oslander (2007) adds a crucial rider: a focus less on public intellectuals as ‘super-stars’ illuminating the public sphere and more on the collaborative contributions of what he calls ‘the collective intellectual’ is likely to produce a genuinely public geography that is both more effective and more democratic. There have been parallel developments in other fields—public anthropology, public history and public sociology, for example—but some of the most impressive have been interdisciplinary: see, for example, the international forums on ‘public issues’ published by the US-based International Crisis Group at http://crisisgroup.org/home/index.cfm. Second, there has been a recognition of the importance of the academy as one public among many—and hence on the importance of Education and pedagogy—and it is as well to remember (as the example of the SSRC shows) that the academy and those other publics are increasingly transnational in their composition and concerns. In this sense, perhaps, public geographies can contribute to the deconstruction of the myth of the ‘ivory tower’—universities are enmeshed in wider webs of political, social and economic practices—and also capitalize on the partialities of situated knowledge to articulate new collaborations, develop new conversations and forge new alliances (cf. the People’s Geography Project at http://www.peoplesgeographyproject.org/).

**Public goods** Goods and services that are either freely available to all or provided equally to citizens of a delimited territory. Public goods are normally always provided by the state and fall within three main categories (Bennett, 1980, 1985). First, pure public goods are those that are non-excludable and non-rival in consumption. One person’s consumption does not restrict another person’s. These goods are freely available to all people through a state’s territory. An example is national defence. However, we can also think of global public goods. The eradication of smallpox, for example, would benefit all of humanity, now and in the future. While all public goods should fall within this category, they do not. It is difficult, and sometimes impossible, to ensure the equal provision of public goods. A second type is impure public goods, which are provided at fixed locations or along fixed routes. A park is a public good, and so is a
public transport service. However, due to distance decay, the further a person lives from these immobile public goods, the less is the usage of them, and their (potential) benefit. The conflict over the production of these types of impure public goods, in the form of turf politics, is an important aspect of territorial justice. The third and final type are public goods impurely distributed, due to decisions by the state to vary geographical provision (Bennett, 1990). At each stage of the distribution of public goods, political decision-making will determine how much of a good is provided, when and to whom. So, while one local government might decide not to provide one type of public good, a neighbouring authority might, producing a series of geographies of uneven provision. Moreover, there might be differences within a local or national government territory on the basis of the privileging of one geographical area’s need over another (cf. pork barrel) (Pinch, 1997).

public policy Geographers have paid close attention to the creation, implementation, monitoring and evaluation of public policies. Work in this area has increased in recent years in capitalist countries because of: (a) the growing importance of the state in economic and social affairs, offering enhanced opportunities for such work; (b) increased governmental recognition of environmental and spatial problems awaiting resolution; (c) the desire among individual geographers to contribute to attacks on such problems; and (d) the perceived need for geographers to demonstrate the relevance of their field and so promote their discipline’s claim for resources within higher education institutions in increasingly materialist situations.

Most geographical analyses have been concerned with evaluating policies addressed at identified ‘spatial problems of environment, economy and society’ (House, 1983) and with assessment of their ‘geographical impact and degree of effectiveness’: in the volume of essays that he edited on United States public policy,

...Critique stops short of prescription but there is some attempt to look ahead and also, in some cases, to set the problems within a theoretical, as well as an operational, framework. (pp. v–vi)

He saw the benefits of such work as twofold:

...[T]o non-geographical academic or lay audiences ... [it reflects] a particular set of perspectives on some urgent problems which face policy-makers in our very critical times. To geographers in training, the relevance of applications of the discipline should be a major concern, whether to add practical purpose to their studies, or to point in the direction of possible professional careers outside the education field.

House identified the discipline’s technocratic skills and its practitioners’ ability to synthesize the many component parts of a complex problem as the geographical perspectives most valuable to public policy study (see his survey of early British contributions in House, 1973); later promotions of geographers’ utility have stressed their technical skills, such as those associated with geographic information systems (see National Research Council, 1997). Others, such as C.J. Smith (1988), suggest that because many social problems are exacerbated, if not created, by environmental, time, place and circumstance contexts (cf. contextual effect), then changing those contexts, through the geography of service provision and delivery, can be as influential as moves to solve the problems.

The nature of geographers’ applied contributions has been largely pragmatic, reflecting the available opportunities and the ability of geographers to capitalise on them with their technocratic skills, hence the current promotion of remote sensing and GIS (Openshaw, 1989). Whereas some geographers claim that such involvement is necessary for the discipline’s survival (Berry, 1970; Abler, 1993a), others have queried this by pointing to the role of much public policy as sustaining, if not enhancing, the inequalities and exploitation that are inherent to capitalism: hence Harvey’s (1974b) question ‘What kind of geography for what kind of public policy?’ (cf. applied geography).}

public–private partnership (PPPs) A collaborative project involving the state apparatus and private companies, with the latter involved in some aspects of the provision of
public services. Such partnerships have been promoted as part of the neo-liberalism agenda for two main reasons. Ideologically, private companies are presented as more efficient at managing large projects than the public sector (cf. privatization). Pragmatically, undertaking developments in this way can allow governments to avoid bearing the capital costs in their budgets – thereby reducing the public-sector borrowing requirement and, it is believed, interest rates and/or avoiding large increases in taxes to pay the upfront costs.

An example of such partnerships in the UK has been the Private Finance Initiative launched in the 1990s, whereby contractors undertake the capital works – building a prison, hospital, school, or road, for example – and then lease the facility to the government, which pays for the facility through its current rather than capital account. In some cases, the private contractor may either operate the new facility and pay part of the profit to the government (as with a toll road) or is given some role in its management (as with a place on a school’s governing body) – this is known as the state ‘contracting out’ part of the provision of public services.

Examples of PPPs include New York’s Central Park, which is managed for the City’s Department of Parks and Recreation by the Central Park Conservancy, and an extension of California’s State Route 125 south of San Diego, which was built by a private company – California Transportations Ventures Inc; the Lane Cove Tunnel under Sydney Harbour in Australia was constructed under a similar scheme, with the contractor then operating it on a 33-year lease. In the UK, the National Air Traffic Services (NATS), which control use of the country’s airspace, is part-owned by the government (which has a 49 per cent stake), with most of the remainder held by a consortium of companies involved in the airline business: as with many such projects in the UK, the work of NATS is overseen by an independent regulator, which can control prices and the quality of service provision.

Whether the use of PPPs is either more efficient or more effective is open to doubt. Some claim that the overall cost of the lease-back arrangements will be greater than the initial capital costs, so that PPPs in effect involve the taxpayer creating profits for the private sector, which may be enhanced by the private companies’ employment practices: in response, others argue that without such partnerships many projects would not happen, because the public sector cannot bear their cost without substantial increases in tax rates, which would deter other investment and entrepreneurship.

**public services** Services that are provided by (or on behalf of) the state according to non-market criteria; that is, on the basis of the need for the services rather than the ability to pay. Although the boundaries between what counts as a ‘public’ or a ‘private’ service have historically been subject to change, together with which sector has done the providing, in general services are provided collectively because provision through the market or the third sector is believed to be either inefficient, ineffective or inequitable. Studies inside and outside of geography have tended to focus on a number of areas of public service provision and utilization, such as education, health care and housing (see housing studies: see also Walsh, 1995). In each case a particular type of collective consumption politics has been found to exist, over the provision of the public service and the conditions under which it is provided. Geographers have been particularly sensitive, not surprisingly, to the geographical aspect of provision of services, related to wider concerns over spatial inequalities, territorial justice and welfare geography (Smith and Lee, 2004).

Three arguments have been made for the need for a geographically attuned analysis of distribution of public services and the level of provision: first, that service provision varies by territory; second, that the benefits of a public service decrease the further an individual is away from its provision (cf. distance decay); and, third, that the location of services matters to surrounding areas and neighbourhoods, in the form of externalities – these are impacts that are not part of the initial decision-making process, and can be either ‘negative’ or ‘positive’, although in many cases externalities are both, how you regard them depends on your own position.

Underpinning much geographical work on public services is an attention to the restructuring of the welfare state (Pinch, 1997). Decisions made by the state apparatus, over the provision of public services, reflect wider economic and political processes. Geographical distribution is often the outcome of a range of
For example, politicking by local government, regional voluntary agencies, nation-states and transnational corporations might produce a particular geographical configuration of public service provision. Current concern with the process of neoliberalism, and what this process means for the qualitative restructuring of the state apparatus, lies behind recent work on public service provision and consumption (Peck, 2001). As we witness a variety of provision arrangements emerging in different countries, between governments and private-sector companies, so tensions over the defining and the use of terms such as ‘equity’ and ‘efficiency’ take on extra importance. What is meant by a ‘public service’? Who has access to it and at what cost? These are questions that currently unite those working on the geographies of public services and those working on issues of state restructuring, in different regions of the world and in different areas of policy.

public space  Space to which all citizens have a right of access. Public space must be juxtaposed with private space, or space over which private property rules are in operation. Central to those rules is the right of owners to exclude others from the use and enjoyment of a space. Public space, conversely, is presumptively open to all. The archetypical public space is the plaza, street or park, the ‘traditional public forum’ characterized by the US Supreme Court as those places that have immemorially been used for public assembly, debate and informed dissent. An array of ‘semi-public’ spaces can also be identified, such as the airport or university.

To speak of public space is necessarily to speak of the public sphere, the realm of collective opinion and action that mediates between society and state. Most famously, Jürgen Habermas characterized the public sphere as the site of deliberative and rational communication, within which free, rational discourse can occur between citizens (Habermas, 1989 [1962]; see also citizenship), distanced from the particularities of the state, the economy and the private domain (see private and public spheres). While membership in the public has long been constrained by exclusions of gender, class and race, it still holds normative appeal. Signalling a site of inclusion and acceptance, outsiders have long struggled for membership in the public sphere.

While the public sphere and public space are not necessarily interchangeable – publics can form in private space, as some feminist geographers (Staeheli, 1996: see also feminist geographies) have noted with reference to the private home – in general, it is in public space that the conversations and encounters of public life become physical and real. For Young (1990a, p. 240): ‘[p]olitics, the critical activity of raising issues and deciding how institutional and social relations should be organized, crucially depends on the existence of space and forums to which everyone has access’. These spaces serve several valuable political ends. The occupation of public space, for Mitchell (2003a), is a crucial means by which the boundaries of the public can be remade. Street protests, for example, can make visible the socially invisible. The physical designation and design of public space itself can also become avenues for the negotiation of politics (Low, 2000) and forms of public memory, as well as collective forgetting (Burk, 2003). The encounters with difference that occur in public space can also foster the formation of an inclusionary ethos, as we learn to accommodate those people and interests beyond our own familiar contacts and ways of life.

For one constituency, however, the very diversity and unpredictability of public space undercuts the value of publicness. The rising homeless population (see homelessness), combined with a law and order ethos, has prompted regulation targeted at ‘disorder’ in public space (such as panhandling). The exclusionary logic of such intervention has prompted some to posit the end of public space. Scholars have also traced the privatization of public space in the Western city, worrying at its effects on political activity and social life (Kohn, 2004).
quadrat analysis A method of point pattern analysis widely used in ecology, particularly in the analysis of plant distributions and adopted for geographical use. A rectangular mesh is laid across an area and the distribution of points in each rectangle counted. That distribution can be modelled using a variety of procedures to assess whether it conforms to what would occur under a random allocation process; is significantly clustered in some portion of the space; or is more regular than random. Central place theory, for example, predicts that the distribution of settlements in a rural area would fall into the third of those categories, whereas theories of agglomeration suggest that industrial plants should be significantly clustered. (cf. categorical data analysis; poisson regression). Quadrat analysis can generate local statistics, but artificial boundaries imposed around the study region at the limits of each quadrant affect their utility: a more sophisticated approach, taking a more continuous definition of space, is geographically weighted regression. quadtree A procedure for compressing the file size of geographical data sets that works by splitting a study region into four quadrants – as with the division of a rectangular area into four smaller rectangles – and then recursively splitting the quadrats until each is homogeneous on defined variables of interest that it contains. Quadtrees are also used in geographic information systems to index phenomena within an area – such as points, lines and areas – according to their spatial location. The approach assumes spatial autocorrelation in data sets and allows them – especially those in a raster format – to be efficiently sorted, explored and disseminated (e.g. over the Internet). RJ

qualitative methods Guidelines to frame research questions, assess what counts as authoritative evidence and knowledge, and collect interpretable data, and distinguished from quantitative methods. The discipline of geography has a long tradition of qualitative methods, and it has been argued that the prioritizing of quantitative methods, associated with the quantitative revolution of the 1950s and 1960s, was an aberration within the discipline’s history (Winchester, 2000). Explicit calls for qualitative methods came in the late 1970s from humanistic geographers, in reaction to what was perceived as the economic determinism, one-dimensionality and objectification of social life within spatial science (Ley and Samuels, 1978). There were (at least) two methodological strands to humanistic geography: an historical and hermeneutic understanding of the production and meaning of landscape, and another within social geography that drew upon phenomenology and symbolic interactionism, and sought to understand social worlds from insiders’ perspectives, often through participant observation or ethnography (Limb and Dwyer, 2001). Through the 1980s, feminist geographies took up and expanded humanist geographers’ concerns to acknowledge and examine the values, politics and ethics underlying all social research, and the need to understand and document the plurality of coexisting and divergent social worlds in all of their affective intensity and complexity. Feminists have been particularly concerned to think through implications of the positionality of the researcher and researched, the workings of power within the research process and the responsibility of using research to create social change. The influence of post-colonialism and post-structuralism has furthered these preoccupations. Qualitative methods are now common and seen as appropriate in all sub-disciplines of geography, including economic geography, migration studies, political geography and health geography.

By the 1990s ‘a frightening array of philosophical, conceptual and theoretical terms [were] embedded in the qualitative research literature’, and neat links between philosophy, theory and method were being ‘unpicked’ (Smith, S.J., 2001, pp. 23–4). Nonetheless,
qualitative approaches tend to share some common understandings about ontology and epistemology: social worlds are dynamic and not fully stable or predictable; social life is produced through human (and non-human) agency; there are multiple social worlds, with distinctive and sometimes competing social meanings, competencies and practices; it is important to understand social life as it is experienced; knowledge is situated and partial (see situated knowledge); theory is to be developed through empirical research rather than tested empirically; the subjectivity of the researcher and researched is a factor in every stage of the research process; the production of knowledge is an inter-subjective, relational process between researcher and researched; and the researcher has ethical and social responsibilities to the researched (Limb and Dwyer, 2001). Smith argues that the choice of qualitative methods goes beyond these issues of ontology and epistemology, and is fundamentally a political decision: “We choose these methods . . . as a way of challenging the way the world is structured. . . .” The debates about power, positionality, reflexivity and ethics are complex, and what has been called a crisis of representation began in the mid-1980s. Crang (2003) notes that such debates have progressed beyond the simplistic dichotomies between ‘insiders’ and ‘outsiders’ typical of earlier discussions to more nuanced considerations of ‘betweenness’ or working ‘alongside’ research participants. Concerns nonetheless linger that qualitative researchers – like all researchers – unwittingly rely upon class, colonial and/or racial privilege to gain access to informants and other information, and to produce knowledge that benefits mainly themselves. For instance, Chari characterizes ethnography as ‘a process of alienation, through which, for instance, ethnographers poach on working-class narratives for very different ends: like getting a job or tenure’ (2003, p. 171). Such criticisms have provoked qualitative researchers to rethink their research encounters, to experiment with new ways of producing and judging knowledge and truth, and to consider a broader range of knowledges as useful and relevant. Reflecting upon their work in Pakistan, Butz and Besio (2004) consider the concept of autoethnography as one means of repositioning research subjects as active transculturally knowing subjects rather than ‘native informants’. Autoethnography attends to the ways in which research subjects actively produce and represent themselves within the terms of dominant discourse, and complicates the boundary between authentic truth and manipulated (and manipulative) self-presentation or performance. Butz and Besio describe how they have organized their research to support their research participants’ own projects of self-representation, thereby ‘multiplying the communicative resources available to them’ (Smith, S.J., 2001b, p. 27). Nagar has entered into another kind of collaborative research endeavour with eight development workers in Uttar Pradesh, India. Calling themselves the Sangtin Writers Collective, they have co-authored a book in which seven grassroots workers write intimately and autobiographically about their lives. This book, first published in India in Hindi in 2004, and more recently in the United States in English (2006), has created controversy in India because of its detailed critique of the politics of the non-governmental organization for which these women worked, and has become a catalyst for organizing among other grassroots workers. There are now many examples of collaborations in participatory action research (Pain, 2004), which tends to be different from, and indeed can be at odds with, the goals of applied geography (the latter is often more closely aligned with the priorities and perspectives of the state). More broadly, Smith argues that ‘Qualitative research is a mode of interference. If this interference is “wrong”, such approaches should be discontinued; they must be unethical. If it is “right”, a lot more documentation and debate are needed on where this interference is going, whose interest it advances, what form it takes and why it is important’ (2001, p. 27).
There are many different qualitative methods, and typologies for classifying them. Winchester (2000), for instance, identifies three categories of qualitative methods: oral (e.g. unstructured interviews and interviewing, focus groups, and life histories), textual analysis (see text and textuality) and participant observation (or ethnography). Despite the diversity of qualitative methods used by geographers, Crang (2002, p. 650) notes a surprising tendency to favour interviews over ethnography – surprising because ethnography would seem to be more in line with field-based geographical traditions. Yet Herbert (2000) has calculated that only 3–5 per cent of journal articles draw on ethnographic research. The reasons for this are various, and include: difficulties in gaining access (McDowell, 1998); challenges of doing ethnographic fieldwork within existing institutional and funding time frames (Cook, 2001b) and disciplinary scepticism about the merits of ethnography (Herbert, 2000).

Two further methodological omissions have been noted. First, visual data tend to be under-used, relative to oral testimony or text. Crang (2003, p. 500) reasons that qualitative researchers have been influenced by critiques of vision as a medium for a detached, masculinist, objectifying gaze: ‘If copresence is the privileged ground of qualitative truth claims, it is against a foil of “bad” vision’ (see vision and visuality). Especially given heightened concerns about the politics of representation, ‘qualitative fieldwork almost turns away from the visual to avoid accusations of “academic tourism” and objectification’ (p. 500). Rejection of the visual is, however, by no means complete, and non-representational theory and a focus on performance and the body have generated many intriguing experiments with visual data and methodologies, some of which are reviewed by Crang. In her textbook on visual methods, Rose (2007 [2001]) provides an excellent overview of a wide range of visual data; questions that can be addressed through them; and a variety of strategies for analysing them. An over-emphasis on discourse and representation grounds a second concern about the limitations of geographers’ use of qualitative methods: this is that too little attention has been directed to how people do things, as opposed to how they see the world or what they say about it. Smith argues that this has prompted a ‘second crisis of representation’ that focuses on the limits of representability (Smith, S.J., 2001, p. 28), and the importance of knowing through practice and recording fully sensual, richly emotional, momentary practices of social lives. Although qualitative methods are now widely used throughout the discipline, Thrift (2000a, p. 244) notes that even ‘cultural geography still draws on a remarkably limited number of methodologies – ethnography, focus groups, and the like – which are nearly always cognitive in origin and effect’. Large claims have been made of the methodological implications of non-representational theory: it is ‘suggestive of nothing less than a drive towards a new methodological avant garde that will radically refigure what it is to do research’ (Latham, 2003, p. 2000). Writing in 2005, Lorimer notes that ‘the creativity [promised by non-representational theory] in research design and method still needs to be unshackled’ (p. 89). Given the emphasis on knowledge through practice, there is renewed interest in symbolic interactionism, phenomenology and ethnomethodology. As much as using radically different methods, it may be a matter of re-examining the potential of existing ones; for instance, to excavate everyday practices in archival evidence, or to conduct, experience and record interviews as fully embodied conversational performances in which subtle shifts in affect, tone and bodily comportment are as significant as what is said. And an argument that social life exceeds discourse need not lead researchers away from discourse; as Nash (2000) has argued, even a practice such as dance – one that drew a great deal of attention in early formulations of non-representational styles of thinking – is not excessive to discourse but, rather, is a complex amalgam of discourse and embodied knowledges. Language itself has multiple relations to action: Chari (2003) draws on linguistic anthropology to consider language as an indexical and not just referential practice, and to consider the multiple relations between language and action.

Given an enquiring attitude about what counts as useful knowledge and recent interest in performance and the ‘doing’ of social life, qualitative researchers are reassessing what counts as valuable research ‘products’, including relatively private and fleeting ones (Thrift, 2000). For instance, whilst conducting an ethnography in a village in Pakistan, a Muslim community in which women supposedly disapproved of being photographed, Besio (Besio and Butz, 2004) was asked by some of the resident women to photograph them privately in out-of-the-way places. Besio reads these secretive photography sessions as expressions
of resistance to masculinist community norms. Her research thus generated a practice of resistance that could not be made public, at least at the research site. Pratt (2004, p. 193) has urged that we consider the research process itself as an important research outcome: ‘We might think of it as a space . . . from which to speak and perform the unspeakable . . . The written traces, for example [academic] text, are but one outcome of a process that far exceeds them.’ Writing and other forms of representation (such as video or photography) can be a significant part of the actual research process in qualitative research; representation is a means of doing the research, of making creative connections and developing interpretations. Different ways of understanding can be communicated through different media (Berg and Mansvelt, 2000).

Despite the widespread use of qualitative data, some scepticism remains about the credibility of qualitative data. Baxter and Eyles (1997) are concerned that qualitative geographers often have not been sufficiently transparent about their methodology. There is a danger of ‘mining’ qualitative interviews for enticing quotes that selectively advance the researcher’s interpretation, and of presenting de-contextualized snippets of conversation. There is also a risk of stereotyping respondents by reading across interview transcripts to identify common themes rather than studying the contradictions and complexity within individual interviews. There are many different strategies for analysing qualitative data (there are 43, according to Crang, 2005). Crang (2005) distinguishes three broad approaches: developing grounded theory, analysing the formal structure of the text or transcript or image, or reading qualitative data as narrative. McDowell (1998) describes a process of repeatedly reading her transcript data, first for plot and then for representations of ‘self’ (also, for a strategy for analysing narrative genres, see Chari, 2003). One characteristic of the best qualitative research is the immense volume of data collected, and although there is no substitute for examining the data closely and repeatedly, a number of computer software packages are available to systematize transcript data and to assist in coding it (Peace, 2000).

Although qualitative methods have often been conceived as opposite or even opposed to quantitative methods, this is an unproductive way of conceiving the distinction. Critical realism was one important moment for thinking of the two approaches as compatible: extensive methods (often quantitative) were seen to be especially useful for describing patterns, and intensive methods (typically qualitative ones) more effective for studying causal processes (cf. extensive research; intensive research). More recently, the call of mixed methods has been tied to the concept of triangulation, which involves exploring processes from different angles using different methods, in order to assess the validity of each data source and method, and more fully understand the process. Nightingale (2003) links the utility of mixed methods to the concept of situated knowledge: she suggests that a mix of qualitative and quantitative methods allows the researcher to better understand the limits of knowledge acquired through any one methodological approach. Different approaches resonate with different audiences – for instance, state funding bodies and policymakers are typically more convinced of the ‘scientific merit’ of quantitative techniques, which they sometimes designate as ‘evidence-based’ research (Mountz, Miyares, Wright and Bailey, 2003). Blending qualitative and quantitative methods may allow a researcher to reach different audiences in more authoritative ways.

quality of life A concept linked to that of social well-being, which is based on the argument that the human condition should be evaluated on a wider range of indicators than just income – whether at the individual level or through national aggregates (such as gross national product and gross domestic product). Work on the quality of life was introduced to geographers in the 1970s in studies of territorial social indicators (Smith, 1973; Knox, 1975), which focused on separate dimensions of collective well-being, such as income, wealth and employment, the built environment, physical and mental health, education, social disorganization, social belonging, and recreation and leisure. Maps of these indicators, at a variety of spatial scales from the international to the inter-urban, provided evidence on geographical variations in well-being, with which researchers could address the question of ‘who gets what, where?’ (Smith, 1977).

Other concepts, such as freedom (cf. human rights) and happiness, are frequently related to measures of the quality of life that individuals and societies experience, although
much work on happiness shows that – to the extent that it can be measured – it does not increase above a certain threshold income: people may be more content and live more comfortable lives with higher incomes, but they do not feel any happier (Layard, 2005).

**quango** An acronym for quasi-autonomous-non-governmental organizations. These are established and financed by governments to perform public functions in areas of policy such as education and health care. Quango members are appointed rather than elected, and are drawn from private, public and third sectors. Since the 1970s, quangos have grown both numerically and in terms of the areas of the world in which they can be found. This growth reflects a general trend in national governments changing how they govern, involving new forms of organizations in their activities. The incorporation of these organizations into the state apparatus raises issues of accountability, democracy and transparency in public decision-making.

**quantitative methods** Mathematics has always been a foundation of geographical practices. For many centuries, it underpinned the development of cartography, providing the techniques (notably geometrical and trigonometrical) deployed in map-making – in establishing exact locations (increasingly through the universally adopted graticule of latitude and longitude and the national surveying systems based on that matrix) and in portraying those locations in map form. With the latter, for example, much effort was (and still is) expended on the development of map projections with which to portray a spherical reality on to a two-dimensional surface. Increasingly, however, this work has been separated from academic geographical practices into separate disciplines (such as geodesy).

Although, as with almost all changes within a discipline, earlier exemplars can be identified, the post-1945 decades saw a major shift in geographical practices associated with a widespread adoption of quantitative methods in human and physical geography – a period widely known as the discipline’s quantitative revolution and very much linked to the adoption of an explicitly theoretical approach to the discipline’s subject matter. This shift was associated with scholars located at a number of institutions, initially in the USA and then also in the UK (Johnston and Sidi-way, 2004a), but the dominant core was located at the Department of Geography in the University of Washington, Seattle, in the early to mid-1950s, when a number of graduate students coalesced around two individuals – Edward Ullman and, especially, William Garrison. Their core concern was the application and development of location theory (especially that based in neo-classical economics), with quantitative methods identified – as in other social sciences, notably economics and sociology at the time – as a means of both expressing theories in a formal language and empirically testing hypotheses.

These two core activities drew on different quantitative methodologies: the expression of theories involved mathematical argumentation and representation (including modelling), whereas hypothesis-testing used statistical procedures, expressing the outcome of empirical research in probabilistic terms. In some cases, mathematical modelling preceded empirical work, providing the formal basis for hypothesis generation; in others, statistical analysis was either based on more informal forms of argument leading to some form of expected empirical outcome, or involved exploration of numerical data without any clear expectation as to the likely outcome (cf. exploratory data analysis). These two approaches (especially that involving statistical analysis) spread rapidly through the 1960s and 1970s from the core institutions in Seattle and other US centres, alongside parallel and linked developments in the UK (Barnes, 2004b, 2008b; Johnston, Fairbrother, Hoare, Hayes and Jones, 2008): according to Burton (1963), geography’s ‘quantitative revolution’ had succeeded by the early 1960s, although circumstantial evidence suggested that it never dominated human geography (Wheeler, 2002).

Much of the mathematical modelling underpinning quantitative work in human geography has focused on either spatial patterns – such as the distribution of settlements, as in central place theory – or spatial interaction (notably various forms of migration and communication). The goal was to express the subject matter under consideration in mathematical terms. At the core of much work on spatial interaction, for example, was an analogy with Newton’s famous formulation, which posited that the volume of interaction between two places was positively related to some index of the generating capacity at each place and negatively related to the
distance between them (the so-called distance-decay hypothesis based on assumed frictions of distance). This could be expressed as a simple formula (as in the well-known gravity model), but the formulation was later extended to present a more realistic representation through the adoption of entropy-maximizing models. Similar approaches presented the spatial structure being investigated as a system, with nodes (such as towns) and links (transport routes). They modelled various aspects of those systems – the optimum number and location of warehouses in a distribution network, for example, or the shortest route involving visits to three or more nodes on the network – using a variety of mathematical techniques, such as graph theory and linear programming (cf. optimization models). Changes of and to those structures were also analysed, notably through models of spatial diffusion.

Many of these early approaches relied on a relatively simple conception of spatial structure, in which distance was the foundational variable to which many of the key relationships were linearly related (albeit through non-linear transformations in some cases: see Cox, 1976). More sophisticated mathematical modelling procedures were later adopted, incorporating non-linear relationships between elements within the system (such as catastrophe theory and chaos theory).

Most statistical analyses undertaken by human geographers are based on the general linear model – notably those components that identify either the relationship of one variable to another (regression, which indicates the degree of change in one variable relative to the amount of change in another) or the strength of such relationships (shown by correlation coefficients). Their introduction – as exemplified by the first textbook on using statistical methods in geography (Gregory, 1962) – was initially presented by some simply as the proper way to present quantitative material and relationships (Gregory, 1971), with formal statements replacing the vagueness of ordinary language (Cole, 1969: see also process). But statistical procedures soon became the predominant means whereby analysts tested hypotheses about spatial patterns and processes, with the findings expressed as probability statements – the likelihood either that what had been observed in a sample of observations also held in the population from which that sample was drawn (cf. sampling) or that the relationship identified could have occurred by chance rather than as the result of some assumed causal sequence whereby changes in one variable stimulated changes in another (where, for example, $x$ is the distance between a pair of towns and $y$ is the number of migrants between them). Thus applications of statistical methods involved combining reasoning methods that are both deductive (formal hypotheses regarding the size, strength and direction of relationships among variables are stated and those expectations compared against empirical data) and inductive (patterns are identified in data sets that suggest ordered behaviour).

By the 1960s, some geographers had become aware of potential difficulties of applying standard statistical procedures (such as those derived from the general linear model) to geographical data because of the issue of spatial autocorrelation, whereby the assumed independence of observations could not be sustained. Tobler (1970), for example, had posited a ‘first law of geography’ that ‘everything is related to everything else, but near things are more related than distant ones’. Thus the value of an observation at one place – the level of unemployment, for example – might well be related to the value at adjacent places, and incorporating all of these values into an unadjusted regression or similar model could violate its foundational assumptions and generate unreliable estimates – of, say, the relationship between unemployment levels and house values across a set of counties. Techniques for analysing spatial data that take such autocorrelation into account and provide reliable estimates were thus developed – forming the basis of an approach to spatial data analysis increasingly widely adopted across the social sciences and known as spatial econometrics. Those, and many other, approaches have been increasingly facilitated by the development and availability of geographical information systems.

By the 1970s, the approach to human geography widely known as spatial science or locational analysis was coming under increasing criticism from a number of directions. Many were associated with the assumed link between quantitative analysis and the philosophy of positivism – the goals of spatial science, it was argued, involved a search for laws of spatial order, in terms of both patterns on the ground and the behaviour that gave rise to those patterns. Some of these criticisms emanated from adherents to a Marxist or radical geography, who argued that a focus on the spatial superstructure (cf. infrastructure) ignored the true processes involved in
the creation/re-creation of geographies of uneven development and the (class-based) power relations that underpinned them. Other critiques emanated from what became known as humanistic geography and the variety of approaches to social and cultural geography that emerged in subsequent decades, which focused on spatial science’s implicit characterization of decision-making as either deterministic (and thus denying the free will inherent in human agency) or influenced by economic factors only, thereby ignoring the social and cultural contexts of decision-making – not least those associated with gender and ethnicity.

To some extent, these critiques were anticipated by geographers working with quantitative methods in the spatial science genre. Many soon became aware that the complexity of contemporary society meant that the relatively simple locational models that they were applying were insufficiently sophisticated to incorporate the wide range of contextual and other variables that can influence spatial behaviour. They therefore shifted their focus away from those models that portrayed a rigid, geometrical spatial order towards more general models of locational decision-making that emphasized context – what became known as behavioural geography. They sought order – common patterns of decision-making – in non-deterministic situations, much as suggested in the attempt through structuration theory to eliminate the binary dualism between structure and agency. Behavioural geography’s core argument is not that people are irrational decision-makers but, rather, that they are boundedly (as against perfectly) rational: the boundedness reflects the limits to their information, their ability to process it and the utility functions that they apply when evaluating options. This does not mean that everybody has to be treated as both unique (having characteristics that nobody else shares in total) and singular (sharing no characteristics with others), so that no general patterns can be found and theories developed. Rushton (1969) makes this point in contrasting studies of behaviour in space – for example, mapping individual journey-to-work routes – with those identifying rules of spatial behaviour, the general patterns within all those choices that can be uncovered from the individual pieces of data using quantitative procedures, to suggest common behavioural decisions. The reasons for such commonalities can then be explored by, for example, identifying shared information underpinning such decisions, as in Peter Gould’s pioneering work on mental maps, the spatial depictions that we use when evaluating the places we want to visit, move to and so on (Gould and White, 1993 [1974]).

This general approach characterizes the contemporary use of quantitative methods in human geography. Although some have claimed that such work is now virtually absent from human geography’s portfolio and prospectus, much work using quantitative methods continues to be reported in the discipline’s general and specialist journals. As with its predecessors, it concentrates on aggregate patterns in space and their generating processes: the description, explanation and (in some cases) prediction of general patterns of spatial behaviour and their reflection in the landscape. (Note, however, the recent emergence of a ‘new economic geography’ within economics, and the creation of a journal – Journal of Economic Geography – to explore commonalities between that approach and the work of geographers who continue to undertake theoretically inspired quantitative work.)

Much contemporary work follows the behavioural geography rather than the original spatial science paradigm, therefore. Most of it is theory-driven, based on generalized hypotheses of how people behave, but much of the analysis involves exploring data assembled to identify patterns rather than explicit hypothesis-testing. This very largely reflects the ‘immaturity’ of such studies: our knowledge of how people make spatially relevant decisions and behave is limited, and so the best we can come up with at this stage is broad expectations. In electoral geography, for example, there are theoretical arguments that self-interest influences how people vote, with economic concerns underpinning that self-interest. But it may be expressed in different ways: some may vote sociotropically, according to their views of the national, regional and/or local economic situation (voting for the governing party[ies] if they are optimistic about the economic situation but against if they are pessimistic); some may vote egocentrically, according to their perceived personal financial situation; and some vote altruistically, in the interests of their (geographical) neighbours even when these don’t coincide with their own (Johnston and Pattie, 2006). Those theoretically based expectations generate testable hypotheses but – as with the gravity model – they cannot predict in advance the size of the relevant coefficients for each type of
voting, because of the many other contingent factors (some of them spatial in nature) that influence electoral behaviour.

This example illustrates the dominant focus within contemporary quantitative human geography, not – as it was 50 years ago – on the orderly arrangement of points and lines in the landscape, and of people, ideas and commodities flowing through those spatial structures (as postulated by Haggett, 1965), but rather on common patterns of behaviour in similar contexts – or common realizations of human agency within particular contextual settings. The emphasis has shifted between two of geography’s fundamental concepts, from a focus on space to one on place. Within that changed emphasis has come the adoption of new quantitative procedures that emphasize the important role of place as context – such as GEOGRAPHICAL ANALYSIS MACHINE, GEOGRAPHICAL EXPLANATION MACHINE, LOCAL STATISTICS, GEOGRAPHICALLY WEIGHTED REGRESSION, MULTI-LEVEL MODELLING, the MODIFIABLE AREAL UNIT PROBLEM, ECOLOGICAL INFERENCE and the ECOLOGICAL FALLACY.

Contemporary use of quantitative methods in human geography entails exploring patterns and processes involving large numbers of decision-makers, seeking order in often complex situations (Haggett, 1990). Even when data are available on individual decision-makers, the goal is to distil general patterns – as in Rushton’s distinction between behaviour in space and rules of spatial behaviour. Unlike other approaches to human geography, therefore, spatial science is macro/meso in scale, rather than micro – though it may deploy micro-scale data in its search for macro/meso-scale patterns. Its findings might pose questions that can only be addressed by studying individuals, but its core methodologies focus on wholes rather than parts.

This approach is the only one possible given certain subject matter. Patterns of (changing) regional development and underdevelopment, for example, can only be studied as statistical aggregates – as can many indices linked to this concept, such as inflation, unemployment rates, land values, house prices, PRODUCTIVITY and so on. Aspects of our worlds are only accessible in such formats, and are sensibly analysed quantitatively. In other cases, whereas individual-level data are available (or can be obtained through bespoke SURVEYS) – on illness, turnout at elections and so on – much can be gained from aggregating them and studying general patterns, of morbidity and mortality rates, for example. Much work in, for example, POPULATION, MEDICAL, SOCIAL and ELECTORAL GEOGRAPHY is of this type – though such sub-disciplines are not constrained to spatial scientific approaches.

A further justification for macro-/meso-approaches lies in the probabilistic nature of much of our understanding and representation of the world. It is generally accepted that smoking causes lung cancer, for example, but not all smokers get lung cancer and not all people who get lung cancer have smoked. It is a probabilistic relationship. Part of the reason why we cannot say that smoking causes lung cancer without qualification is because other variables can either accelerate or decelerate, even block, the processes involved; part also reflects our incomplete knowledge (constrained because of the difficulties of conducting controlled experiments). Similar arguments apply to a whole range of behaviours studied by (physical and well as human) geographers: the processes involved are so complex and difficult to unravel – because we cannot conduct experiments (although a range of new techniques may be of value in such situations: Sherman, 2003; Dunning, 2008). Hence work in spatial science is almost of necessity conditional: it represents the state of our current understanding and can only be phrased in probabilistic rather than deterministic terms.

The meso-/macro-patterns in many aspects of contemporary society that are quantitatively described and analysed by social scientists are relevant to people’s daily lives and experiences – the ‘meaningful nature of life’ explored in other geographical practices. Levels of ethnic SEGREGATION in urban neighbourhoods and schools (see URBANIZATION) provide contexts within which not only lives are (partially) lived, but also people’s life chances and relationships are influenced. Geographical concentrations of POVERTY similarly structure many people’s life chances, while biased election results reflect the operation of the aggregation and scale issues underpinning the modifiable areal unit problem (Johnston and Pattie, 2006).

Alongside their intrinsic interest and importance to understanding spatial patterns and behaviour, therefore, meso-/macro-scale work is relevant to PUBLIC POLICIES – either studies of their impact on geographies or analyses of geographical patterns that call for public intervention. Geographies of MORTALITY, for example, may identify areas where further investment of medical resources is warranted. Much public policy has impacts – direct and indirect – on topics of interest to
human geographers and, although directed at individuals, is delivered to areas, as with the location of healthcare clinics: if the world operates through spatial aggregates, then it should be analysed accordingly (though not exclusively so).

Similarly, whatever the immense variety of human spatial behaviour, the public policy that intervenes in it in some way (and much private-sector policy too) is almost invariably phrased in aggregate terms. New highways are planned to link places where demand either currently outstrips supply or modelling suggests that it soon will. New commercial establishments are located where potential (unfulfilled) demand is deemed greatest (and usually implies some distance-decay pattern in usage, as represented by the gravity model): much APPLIED GEOGRAPHY (such as that using GEODEMOGRAPHICS and other spatial analytical procedures) is based on this aspect of Tobler’s law.

Many aspects of the positivist approach have long been abandoned by almost all spatial scientists: they adopt some of its precepts – particularly that the things they study can be observed and measured; that the statements which they derive can be tested for their veracity; and that their studies can be replicated. For them, knowledge-production involves careful observation, measurement, analysis and interpretation, generating statements that identify synoptic patterns – the broad pictures that might then be decomposed to see how they are produced and what they mean for the people who live in them. They do not – as Fotheringham (2006, p. 239) puts it – ignore ‘all the emotions and thought processes that are behind what is sometimes … highly idiosyncratic behaviour’: they accept those as valid topics for study, calling for different approaches. For spatial scientists, a whole range of subjects can be addressed at the aggregate level using quantitative methods, from which valid generalizations can be drawn to illuminate aspects of the human condition. And these can be linked to studies using non-quantitative practices – as proponents of ‘mixed-method’ stress. Quantitative methods thus remain at the core of the geographical enterprise.

Fotheringham, Brunsdon and Charlton (2000); Haggett (1990); Wilson and Bennett (1985).

quantitative revolution The ‘radical transformation of spirit and purpose’ (Burton, 1963, p. 151) that Anglo-American GEOGRAPHY experienced during the 1950s and 1960s following the widespread adoption of both inferential statistical techniques and abstract MODELS and theories. In the process, the dominance of an old IDIOGRAPHIC geography characterized by a focus on AREAL DIFFERENTIATION was displaced by a new NOMOTHETIC geography conducted as SPATIAL SCIENCE.

The quantitative revolution first emerged in the mid-1950s as a series of local affairs crystallized around one or two key individuals. In the USA, the Department of Geography at the University of Washington in Seattle was key, as was the University of Iowa in Iowa City. At Washington, it was the presence of Edward Ullman and William Garrison that was crucial, and at Iowa, Harold McCarty. In 1954 Garrison gave the first advanced course in statistics in a US Department of Geography, and the following year his Washington students, nicknamed the ‘space cadets’, were among the first on campus to make use of the new IBM 604 computer (also a national first). Those students subsequently proved critical in diffusing the quantitative message, which they did by quickly establishing themselves and their research agenda at several prestigious US universities during the early 1960s, including Chicago, Northwestern and Michigan. Outside the USA, Peter Haggett and Richard Chorley in the UK (affectionately described by David Harvey as the ‘terrible twins’ of British geography) and Torsten Hägerstrand in Sweden were central in establishing a European beachhead.

By the mid-1960s, a network was in place that connected quantitative researchers and Departments of Geography on both sides of the Atlantic. Holding it together were two new sets of geographical practices: technique-based practices that included computerization, and the study and application of ever more complex statistical and QUANTITATIVE METHODS; and theory-based practices that involved conceptualizing LOCATION and SPACE in rigorously abstract terms. Before the 1950s, human geography was resolutely a-theoretical (see also EMPIRICISM). The quantitative revolution brought a cornucopia of theoretical models typically imported from other disciplines. From physics came GRAVITY MODELS and later ENTROPY-MAXIMIZING MODELS; from economics, often by way of REGIONAL SCIENCE, came the models of a dispersed German school of LOCATION THEORY; from sociology came the urban models of the CHICAGO SCHOOL, together with urban FACTORIAL ECOLOGY and the RANK SIZE RULE; and from
geometry via transportation studies came networks and graph theory. And from the philosophy and history of science came a model of ‘the structure of scientific revolutions’ (see paradigm) that could be used, rhetorically at least, to legitimize the quantitative revolution as a genuinely scientific revolution. In the process the dominant stream of research in human geography moved from a field-based, craft-form of enquiry to a technical, desk-bound one, where places were analysed from afar.

Peter Gould (1978), one of the revolutionaries, labelled the era of the quantitative revolution, ‘The Augean period’, after the mythic Augean stables that – after thirty years of neglect – were cleaned all of a piece by Hercules. Equating quantitative revolutionaries with Hercules and an earlier non-quantitative geography with the Augean stables speaks to at least two sociological processes marking the revolution. (1) The heroic depiction points to the quantitative revolution’s profound masculinism (and, arguably, to its whiteness too). Initial proponents and expositors were all men; there were virtually no substantive studies of women; and the disembodied, totalizing knowledge produced was phallocentric (see phallocentrism; see also situated knowledge). (2) The cleansing metaphor indicates how desperately keen revolutionaries were to quarantine themselves from the past. Partly this was intellectual, but, as Taylor (1976) argues, it was also for internal sociological reasons. To move ahead, to secure early promotion and status, it was necessary to do something different. For a group of very bright, young, ambitious and competitive male scholars, the quantitative revolution was the perfect vehicle.

At some point in the late 1960s, or early 1970s, the grip of the quantitative revolution on the discipline loosened. There are at least two reasons. First, a different kind of world was emerging that was more restless, and less innocent than before. Great debates were happening around issues of poverty, civil rights, the environment, gender and racial equality, and war, but the quantitative revolution seemed unable or unwilling to address them. The ensuing relevance debate of the early 1970s left quantifiers flat-footed. As Harvey (1973, p. 129) dammingly put it, ‘There is an ecological problem, an urban problem, an international trade problem, and yet we seem incapable of saying anything of depth or profundity about any of them. When we do say something, it appears trite and slightly ludicrous. In short, our paradigm is not coping well. It is ripe for overthrow.’ Second, an academic generation had passed since the first quantifiers, and the time was ripe for change. A new vocabulary was forged to mark off the old from the new, in this case, one principally derived from Marxism (Harvey, 1973). There were other, immediate contenders too, including a humanistic geography that sought to develop human geography’s connections with the humanities rather than the social sciences. But the important point, and why the quantitative revolution remains a watershed in geography’s recent history, is that Marxism and its successor projects persisted with a theoretical vocabulary. (It is as well to remember that the humanities are every bit as ‘theoretical’ in their sensibility as the social sciences.) Certainly the meaning of theory altered, as many different avenues were explored, but the continuity of a theoretical vocabulary has proven more important in subsequently shaping the discipline than rupture.

Queer theory A panoply of always-questioning and destabilizing theoretical and intellectual movements that centre on the significance and complexities of sexualities and genders. It emerged in the 1990s (see de Lauretis, 1991) within the humanities, but has travelled into the social sciences, and so into human geography. By its very nature, the term resists being pinned down or essentialized. Above all, queer theory draws on both senses of the term ‘queer’. It refers both to an array of non-normative sexualities and/or desires (lesbian/gay/bisexual/pansexual/asexual/transsexual/transgendered (see psychoanalytic theory), and invokes the sense of challenging norms of sexuality by referencing the curious, odd or strange (de Lauretis, 1991; Jagose, 1996).

Two uses of the term are apparent. First, queer theory is used loosely to describe any theoretically inflected work in gay and lesbian studies. Using the term in such a way frustrates queer theorists who valorize the perspective’s unabashedly and relentless push to critique. Second, and more precisely, as an instance of post-structuralism and post-modernism, queer theory epistemologically challenges the ubiquity of heteronormativity (see homophobia and heterosexism). It perpetually and relentlessly destabilizes our quotidian ideas by rejecting any fixed or stable
notions of SEXUALITY and GENDER, their representations or their effects (see ESSENTIALISM; FEMINIST GEOGRAPHIES; PERFORMATIVITY: see also Jagose, 1996; Sullivan, 2003).

The dilemma with any dictionary definition of this term is that it is meant to refuse fixing or defining, or delimiting a research trajectory, because such a move logically excludes facets of sexualities, or strategies to rethink them. This conundrum reflects the tendency of dominant discourses to assimilate any moves that resist or stand outside of them (see DISCOURSE). Thus there is a discernable anxiety about whether the radical potential of this term is being evacuated as its popularity grows and it is stretched to cover any work being done by or about gays and lesbians (Sothern, 2004).

Queer theory’s relationship with geography has been two-directional, if rather uneven. Queer theorists demand that geographers recognize – and attend to – their own heteronormativity, but it also introduces the problematic of homonormativity, which is to say, the disciplining effects of privileging and imposing any sexuality or desire to the exclusion or stigmatization of others (Sothern, 2004). It has enabled geographers interested in sexuality and SPACE to maintain a focus on PLACE, yet also incorporate an appreciation and awareness of movement, MIGRATION, PLACELESSNESS and multiple SCALES (e.g. Knopp, 2004). Geographers, historians and architects have tried to point out that queer theory’s roots in the humanities, often marked by a suspicion of EMPIRICISM, and penchant for discourse analysis of literary TEXTS, open it to charges of a rather unqueer GEOGRAPHICAL IMAGINATION, where the materiality of the world is sometimes lost in a sea of TEXTUALITY. While queer theorists have been willing to appreciate the significance of SPATIALITY and NATURE–SOCIETY dualities (Halberstram, 2005), they have been rather slow to acknowledge the work of geographers who themselves are informed by queer theory.

QUESTIONNAIRE

A variety of types of questions can be asked, including open-ended ones. Closed-ended questions standardize responses across a given set of responses and are already structured for statistical analysis. Open-ended questions require coding before statistical analysis, but are suitable if the full range of possible responses is unknown, or the topic is a sensitive or complex one that requires some explanation or qualification. Because questionnaire design is so difficult and so important, FOCUS GROUPS can be used to understand interpretations of particular questions and questionnaires are always pre-tested.

Questionnaires are considered by some to be best suited for discovering patterns and less helpful for studying causal relationships. Marsh (1982) assesses these criticisms and provides a careful guide for questionnaire design so as to enhance the utility of questionnaires for statistical causal analysis. This involves collecting data on many different variables, beyond ones identified as independent (causal) and dependent (effect) variables, including possible confounding, antecedent and intervening variables. She also provides guidelines for asking people about their reasons for doing things. This ‘reasons analysis’ involves

An instrument for collecting data for SURVEY ANALYSIS. Every respondent is asked the same questions, in the same way and in the same sequence. This differs from the more open-ended, conversational format of interviews and other QUALITATIVE METHODS. Questionnaires can be used to collect information to classify respondents (e.g. gender, income or age), to learn about their behaviour (e.g. voting practices, number of hours of television viewing per week or recycling behaviour) and to understand their attitudes. Questionnaires may be administered face-to-face, over the phone or via the INTERNET, or they can be mailed and self-administered. There are advantages and disadvantages to each mode of administering questionnaires, including cost, response rate, accuracy of responses and the level of detail that can be obtained. One mode of delivery is not superior to another: the advantages and disadvantages are weighed in relation to the research question.

Because one of the strengths of survey research is the capacity to establish patterns over large populations, questionnaires must be very carefully designed so as to be unambiguous to a large number of people. They must be unbiased and simply understood, with clear instructions of how to respond. There are standard pitfalls to avoid, such as the inclusion of double negatives and double-barrelled questions. Nevertheless, there is no avoiding the fact that questions are inevitably framed from a certain perspective and, in the case of face-to-face or telephone interviews, the presence of an interviewer will have effects that can only be understood rather than removed (see INTERVIEWS AND INTERVIEWING).
asking a series of questions that break the reasoning process down in such a way as to assist the respondent in explaining their reasons. Concerns are also expressed about the accuracy and truthfulness of survey research, and it is as well to remember that some characteristics of the survey context promote truthfulness so as to emphasize these features. These include underlining to the respondent the fact that their completion of the questionnaire is entirely voluntary, and that their responses are a valuable contribution to understanding an important research question.

**Race** A historical means of social classification and differentiation that attempts to essentialize political and cultural differences by linking physical traits (i.e. skin, blood, genes) and social practices (i.e. religion, violence, passion) to innate, immutable characteristics (see Essentialism). Race as a concept presumes that characteristics (tendencies, behaviours, dispositions, interests) of an individual can be projected to understandings of essential traits of a population or that the presumed traits of a population can be discerned through the characteristics of an individual. Though these assumptions have been widely and exhaustively disproven, they still operate as ‘common sense’ in society with powerful and violent effects. As such, race is a social construction but racism is a material fact.

The contemporary meaning of ‘race’ has roots in older forms of hierarchy and classification, but its contemporary form as an innate physiological or genetic means of differentiating individuals and populations is largely the product of eighteenth-century social relationships associated with the European Enlightenment and Colonialism (see also Europe). Most scholars agree that earlier forms of social differentiation and hierarchy were different from modern ideas of race. In the ancient world, for example, the Greeks distinguished between the ‘civilized’ and ‘barbarous’, the Romans between freedom and slavery, and the Christians between the savage and the saved. But in all these cases difference was not fixed: barbarians could become ‘civilized’ in Greek cities, Roman slaves were not determined by inherited traits, and Christians were offered the possibility of salvation through conversion.

The most powerful antecedents to the contemporary notion of race can be found in the Christian notion of the Great Chain of Being, which depicted a hierarchy in the order of things as immutably fixed by God, and the idea of succession to kingship or royalty based on a line of descent (or bloodline). These notions provided the basis for identifying populations through a fixed and defining feature such as blood. In the fifteenth century, for example, it was deemed impossible for Jews to convert to Christianity by virtue of their blood, a doctrine that helped to define the notion of a Jewish population that was supposedly distinctive and unassimilable through its shared immutable qualities. Similar appeals to a naturalized hierarchy were made in the sixteenth-century debates between Bartolomé de Las Casas and Juan Ginés de Sepúlveda, concerning the treatment of the indigenous inhabitants of the Spanish colonies in South America as either child-like human beings (who could thus be converted to Christianity) or ‘savages’ (whose exploitation could be justified through their lower position in the natural order of things). The Spanish Empire developed a doctrine of ‘blood purity’ (*limpeza de sangre*) that allowed and even required the differential treatment of those who could not be converted because of the supposed impurity of their blood, and the subsequent hierarchical classification by blood provided an influential precedent for modern formations of race (Darder and Torres, 2004).

The term ‘race’ came into English usage in the seventeenth century and here too it was most forcefully articulated through Anglo-American projects of colonization in the New World. In developing a concept of Civilization that was supposedly coterminous with the West, particularly in the eighteenth century, Europeans and Americans fabricated cultural and behavioral (‘racial’) traits that legitimized their own superiority and exploitative colonial practices. But these ascriptions were more than the product of an expansive, exploitative and European project of Modernity, and scholars such as Ann Stoler (1995) and Paul Gilroy (2000a) have sought to show that ‘race’ is constitutive of modernity itself.

The modern notion of ‘race’ thus has a complex genealogy, but it has been most forcefully advanced through the claim that it is a demonstrably scientific concept. As such, ‘race’ is inseparable from the development of so-called ‘natural history’ in general and the work of the Swedish scholar Carolus Linnaeus (1707–71) in particular. Linnaeus is usually regarded as the founder of modern scientific systems of Classification. He divided human beings into four taxonomic sub-orders, whose
distinctive traits he directly linked to skin colour. Thus the *Europeaus* was supposedly white, gentle, sanguine, inventive and ruled by law, while *Africanus* was black, crafty, negligent and governed by caprice. In developing this taxonomy, Linnaeus effectively subsumed cultural formations within the taxonomical order of NATURE. In 1745, the French naturalist Georges-Louis Leclerc Buffon (1707–88) explicitly introduced the term 'race' into natural history and, developing Linnaeus’ categories, divided human beings into separate ‘races’. Although Buffon acknowledged the artificiality of these divisions, they were subsequently reified by the German anthropologist and physiologist Johnann Friedrich Blumenbach (1752–1840), who developed a classification of five human types based on cranial skull measurements: this system served as the ‘scientific’ basis for racial classification for almost 200 years – and even though it has been widely repudiated, it is still present in popular culture today.

But it was through DARWINISM and populist simplifications of Darwin’s ideas of ‘natural selection’ and ‘survival of the fittest’ that the most pernicious formations of ‘race’ were naturalized. Most notable was Francis Galton (1822–1911), Darwin’s half-cousin, who applied a version of Darwinian theories to human society and in 1883 developed the concept of Eugenics (‘good genes’) to encourage socially engineered heredity as a means of improving the human race. In the USA, the Eugenics movement found an appreciative audience in the context of increasing IMMIGRATION, POVERTY and violent labour politics, where it seemed to offer a means not only of social improvement but also of social control. The initial focus was on ‘positive eugenics’ through birth control, selective breeding and eventually genetic engineering to assure ‘better babies’; but a ‘negative eugenics’ was subsequently developed, which advocated forced sterilization and segregation to preserve the purity of the white race. These concepts reached their hideous climax in Nazi Germany under the banner of ‘racial hygiene’, when ‘Aryan’ women were impregnated by SS officers, hundreds of thousands of people who were declared unfit were sterilized, and millions more ‘undesirables’, primarily Jews but also gypsies and homosexuals, were murdered to protect the ‘purity’ of the Aryan race (see HOLOCAUST). Here, modern biological racism was taken to its ‘logical’ end, in which some presumed innate behavioral qualities and social status could only be addressed through the extermination of the biology of individuals who were considered the sources of the problem (Larson, 1995: cf. BIOPOLITICS).

Even after the widespread postwar repudiation of Nazi race science and Eugenics, the claim that there is an innate scientific basis to ‘race’, fusing physiological features to social behaviours, is still a common means of social classification, and continues to be a powerful strategy of dividing, ranking and controlling people around the world. Newer efforts from sociobiology, neo-Darwinism, evolutionary psychology, some strains of evolutionary anthropology and biology as well as some versions of genetics continue to search for a physical basis for ‘racial’ difference, while STATE-sponsored systems of racial profiling assume that such a basis has been found and can be deployed as an effective weapon against CRIME OR TERRORISM.

The problem with the debates around race, as W.E.B. Du Bois pointed out over a century ago when he abandoned his efforts to show its erroneous foundation, is that the very idea of race has been so comprehensively woven into the social and psychological fabric of SOCIETY that simply revealing the fallaciousness of racial classification does little to expunge the term or diminish its extraordinary power. He wrote that ‘in the fight against race prejudice, we were not facing simply the rational conscious determination of white folk to oppress us; we were facing age-long complexes sunk now largely to unconscious habit and irrational urge’ (Du Bois, 1986 [1940], p. 296). This realization that constructs of ‘race’ are embedded within the formation of modern human SUBJECTIVITY was developed by Frantz Fanon (1925–61) who, in Black skin, white masks in particular, emphasized how ‘race’ is implicated in both how one comes to know and define a self and how that self is articulated in the world (Fanon, 1967 [1952]). These and other critiques prompted a shift towards an analysis of how ‘race’ comes into being through LAW, popular CULTURE and everyday practices of racial formation (see also POST-COLONIALISM).

The critique of race-based cultural formations has been reinforced by parallel debates within and, indeed, about the very ‘nature’ of SCIENCE. Most famously, Richard Lewontin
and Stephen J. Gould challenged the biological and genetic basis of racial identification, arguing that there is more genetic variation within a nominally ‘racial’ group than between such groups. However, these and other scholars effectively placed nature outside the field of culture and politics, arguing either that ‘race’ was cultural and not natural or that genetic maps could not be projected on to cultural behaviours (Haraway, 1989). As such, the debate often became polarized between nature and nurture: Was race a biological category or a cultural one? Science was assumed to have the authority to speak for nature and, as a result, the cultural politics of the supposed ‘science of race’ was left largely unchallenged. More recent scholarship in science and technology studies by Donna Haraway (1989), Nancy Stepan Leyes (1990 [1986]) and Ian Hacking (1999) has help move away from the nature–culture dualism that underwrote these discussions, and has shown that nature and the voices that speak for and about race and the science of race are always already bound up in politics.

These approaches to understanding race have been echoed in contemporary black cultural studies, Chicano studies, ethnic studies and critical race theory, which have approached racial difference and affinities as constructed through social struggles, shared histories and everyday practices positioning racialized subjects and their formation within multiple relations of power. Rather than fixed difference, ‘race’ is understood as a contingent formation unevenly produced in different times and places with no invariant meaning or universal form (see, e.g., Hesse, 2000; Fregoso, 2003; Moore, Kosek and Pandian, 2003). As such, many scholars of difference have abandoned the term ‘race’ altogether, moving ‘beyond race’ to address the multiple forms and particularities of social relations, and denying any overarching integrity or coherence to race as an analytical concept while still being attentive to the ways in which racism(s) are a lived daily reality.

**racial districting** An aspect of Redistricting within the USA intended to ensure that racial minorities – notably African-Americans and Hispanics – do not suffer from discrimination, through such strategies as Gerrymandering. Under the 1965 Voting Rights Act, states with records of such discrimination are required to get redistricting plans pre-cleared by the Department of Justice. This usually involves ensuring that there are sufficient ‘minority-majority districts’ so that, for example, if 30 per cent of a state’s population is African-American, then 30 per cent of its Congressional Districts should contain an African-American majority. Such schemes remain open to challenge through the courts on other grounds. RJ

Kousser (1999).

**Racialization** A historically contingent and contested process through which racial meanings are extended in attempts to define or redefine relationship, social practice, object, individuals or group. The term has become widely used as a means of stressing that ‘race’ is a social, economic, political and psychological process that must be explained, rather than a biological one that is determined by inherent characteristics (Omi and Winant, 1996). Although its origins date back to the late nineteenth century, its current use can be traced to Frantz Fanon’s exploration of the relational aspects of racial formation and physical and social dimensions of European domination and Colonialism (Fanon, 1967 [1961]). More recently, many scholars have developed reservations about the term because its over-usage and vagueness has led to less rigorous attention to the specific practices and dynamics of racial formation (Goldberg, 2002).

**Racism** Any act that links tendencies, affinities, behaviours or characteristics to an individual or community based on innate, indelible or physiological attributes, intended or not, is an act of racism. Racism is also the prejudice, hierarchical differentiation, discrimination and so on that results from these essentialized understandings of race as an innate factor that determines human traits and abilities. Racism may be manifest individually, through explicit thoughts, feelings or acts, or socially, through institutions and practices that reproduce and essentialize difference and inequities (see Essentialism; cf. Apartheid).
Racism is now so extensively used in political discourse that it often gives the impression of being a timeless universal concept. In fact, the word did not exist in the English language until the 1930s, and only slightly before in German and French. Its rise coincides with the specific context of 1930–40s Germany. Specifically, ‘racism’ at the time was employed as a political critique of the German biologized understanding of race (see HOLOCAUST). Although the roots of the term have a much longer and divergent history, racism as a phenomenon was present in multiple forms before the use of the term. Among these forms were the relational differentiation of the Self and the Other in colonial practices, in which the securing of one’s own positive identity was formed against the stigmatization of the inferior characteristics (often fixed through physical or biological characteristics) of an ‘Other’ (see COLONIALISM).

However, some critics have become wary of understanding racism as simply biological or physical, asserting that CULTURE or ETHNICITY can be reified and naturalized to the point at which they become ‘functionally’ equivalent to biological understandings of race (Fredrickson, 2002). The idea of cultural racism was first presented in 1952 by Frantz Fanon, who saw the emphasis on cultural differences as a modern replacement of biologically based ideas of different races (see Fanon, 1967 [1952]). Still later, Martin Barker pointed to what he called the ‘new racism’ that arose through the conservative political milieu in England in the late 1970s and 1980s, in which conservatives and liberals alike would criticize biological ideas of race only to naturalize ideas of community and culture (Barker, 1981). Etienne Balibar argues that this new racism in EUROPE is actually ‘racism without race’, in which ideas of immutable human difference are used to rigidify racial categories or assert the impossibility of coexistence (Balibar, 1991b, p. 23; see also Gilroy, 2000a). This concept of the ‘new racism’ was taken up by other writers, most notably a group at the Centre for Contemporary Cultural Studies in the UK, who came to understand racism, or more accurately racisms, as highly variable historical formations with shifting meanings that are temporally and spatially uneven and fiercely contested. They, and later others, emphasized the political importance of denying a universal and essentialist understanding of race or racism outside of the historically specific and intimate contexts of their formations and practices (Hall, 1980, p. 336; Gilroy, 1987, 2000; see also Goldberg, 1993; Stoler, 1995). These understandings of racisms as spatially and temporally variable, lacking any thematic unity, or that challenge intrinsic characterizations of race, have been particularly important in contemporary understandings of new forms of biological racism such as new genetic determinism as well as historical and cultural racism, such as post 9/11 racism towards Muslims, and neo-nationalist projects such as the rise of NATIONALISM in Europe. **radical democracy** A POSTMODERNIST or POST-STRUCTURALIST rethinking of modern democratic theory and practice. It takes a broad-ranging and flexible perspective on CITIZENSHIP, emphasizing capacities to ‘be political’ in a DEMOCRACY rather than necessarily on rights-claims or formal membership in a polity. It challenges two popular conceptualizations of the citizen. Rather than locating citizenship as one IDENTITY or PERFORMANCE alongside, but mutually exclusive to, others (such as kin, worker, consumer etc.), as is common in LIBERALISM, or heroically elevating it as the principal and optimal identity of the individual, as is common in COMMUNITARIANISM, radical democracy rethinks citizenship as a potential moment or dimension of any identity when it becomes politicized or contested (Mouffe, 1993). Radical democracy is ‘radical’ because it refuses closure on the questions of democracy everywhere, in all their forms. In other words, it seeks to democratize all aspects of politics, especially at sites of doxa, shared assumptions, or where things are deemed apolitical or pre-political.

Radical democracy has important consequences for POLITICAL GEOGRAPHY. It has been part of a turn towards a more encompassing and theoretically informed way of understanding politics and the political. It has helped geographers broaden their focus on the STATE and sites of politics towards locations in CIVIL SOCIETY, PUBLIC SPACE and the HOME, as well as hybrid spaces such as the SHADOW STATE (Brown, 1997a). Barnett (2004b) has cautioned, however, that the spatial rhetoric in radical democratic theory desensitizes us to different temporal scales so often at work in politics. He insists that we must pay close attention to their complexity, or else UNIVERSALISM will unintentionally creep back into our thinking.
Radical democracy also has implications for social and cultural geography, given its attention to multiple axes of power that work through multiple subject identities (see identity, subjectivity). How identities are enabled and constrained as the subject moves through space, for example, has been a point of interest for radical democratic geographers (e.g. Massey, 1995). Rejecting essentialism, radical democracy implores a sensitivity to the openness and fluidity of the subject. It challenges the will for politics to fixate or prioritize a single identity to the exclusion or devaluation of others (e.g. where orthodox Marxism might privilege class struggle over gender oppression).

This has been challenged by radical geography, which questions how one can have a politics without at least some ethical or political commitments that must be treated as essentialisms. A second criticism takes form around the question of the constitutive outside of the political. Simply put, even the most post-structural of scholars has questioned whether or not we can ever have a democratic politics without some form of a constitutive outside. Whenever there is a ‘we’ (or a ‘here’), there is by definition, a ‘they’ (or a ‘there’) who are ‘outside’ of deliberation or perhaps even recognition. Yet logically such a border itself might be quite anti-democratic. If the promise is to always attack and render such exclusionary political geographies, the political issue at hand becomes deflected, and inevitably lost in an infinite regress of attending to exclusions. Conversely, foreclosures and boundaries around what is worthy of the appellation ‘politics’ or ‘political’ are inherently anti-democratic since they leave no space for those harmed by such foreclosures.

Addressing these paradoxes, political theorists advocate open, iterative and reflexive standpoints in order to address these tensions, but they admit these are by no means ‘solutions’ to the dilemma.

Mouffe (1993); Rasmussen and Brown (2002).

**Radical geography** Approaches to geography committed to overturning relations of power and oppression, and to constructing more socially just, egalitarian and liberating geographies and ways of living. The term came to refer in particular to critiques of spatial science and positivism in geography during the late 1960s and early 1970s, and to attempts to chart alternatives that were socially relevant and sought fundamental change. Many geographers were radicalized by counter-culture movements and by waves of political protest at the time; in particular, struggles involving civil rights and against the Vietnam War, imperialism, poverty and inequality. They reacted against technocratic approaches in geography that were unable to speak to current pressing problems and that served to support the status quo, and they sought to study social issues from contrasting viewpoints, especially those based on socialist, feminist and anti-imperialist perspectives. The establishment of Antipode: a Radical Journal of Geography in 1969 by students and faculty at Clark University, Massachusetts, provided an important forum for Anglophone geographers, with the opening issue declaring that it was both necessary and possible to change university structures and ways of doing geography, and to revolutionize the social and physical environment.

Early issues of Antipode were urgent, questioning, optimistic, combative in style and diverse in content. Articles addressed issues such as poverty, housing, services, planning, research methodologies, imperialism, women and war. The rediscovery of earlier radical traditions of social concern in geography – in particular, the anarchist geography of Kropotkin and Reclus – inspired many. Others conducted advocacy research and experimented with taking geography into the streets, including through Bunge’s ‘geographical expeditions’ that worked with low-income and disenfranchised communities. Organizations such as the Union of Socialist Geographers, founded in 1974, advanced a radical presence in the discipline. According to Peet, however, early radical geography was ‘more relevant to social issues but still tied to a philosophy of science, a set of theories, and a methodology developed within the existing framework of power relationships’ (Peet, 1977b, p. 12). Calls for overhauling the discipline’s theoretical basis to address the deep causes rather than the surface manifestations of problems led to a ‘breakthrough to Marxism’ in the early to mid-1970s, as the work of Harvey and others paved the way for the analysis of capitalism and class struggle (Harvey, 1973, 1999 [1982]).

Marxism became central to much radical geography, which moved from an oppositional and relatively marginalized position to become a major force. Radical ideas and practices developed within feminist geographies, similarly committed to social change but critical of the gender-blindness of other radical
Studies, became increasingly important. Vigorous geographical debates were also stimulated by post-colonialism and concern with sexual liberation (see sexuality and queer theory), as issues of cultural politics came to the fore, with each of these approaches being connected with political struggles inside as well as outside the academy (Blunt and Wills, 2000). In an editorial marking the twenty-fifth anniversary of Antipode, Walker and McDowell (1993, pp. 2–3) signalled this diversity, arguing: ‘No single oppression or axis of social life can be treated as merely secondary or an afterthought of radical research or politics. While socialism and Marxism remain central to the vocabulary of the Left, we hold to no one orthodox view of radical analysis.’

Radical approaches have become increasingly accepted and influential in the discipline, yet much of the earlier optimism about the prospects for fundamental social change has receded. The idea of a ‘common vision’ or project in geography has also been challenged. Some have welcomed the pluralization of the Left, but others have worried about its fragmentation and depoliticization, asserting that while it is necessary to recognize the diversity of current struggles, it is also important to find points of commonality and unity between them in order to enable political change. Many now employ the term critical human geography as a related and looser label for ideas and practices committed to an emancipatory politics, and considerable discussion has recently centred on the effects of institutionalization and professionalization within the academy as well as on political commitment, on activism and on different ways of contributing to progressive social change (including through debates in Antipode about ‘what’s left?’; see also Castree, 2000). Initiatives such as the conferences of the International Critical Geography Group and the development of internet forums are providing new means for developing and debating radical perspectives, and for connecting different forms of radical geography, which have their own geographies and histories. Radical perspectives in geography are further being galvanized by current political struggles against capitalism, imperialism, war and other forms of oppression that underlie the continuing need for approaches that provide ‘[d]issentient thoughts and norm challenging information’, and that are prepared ‘to bring the undiscussed into discussion; to stray beyond established perimeters of opinion; to render the familiar not only strange but, often-times, unacceptable; and to explore the depths of the meaning of “radical” itself as a conceptual rubric’ (Castree and Wright, 2005, p. 2).

Blunt and Wills (2000); Peet (1977, 2000).

**rank-size rule** An empirical regularity identified in the city-size distributions of some countries and regions. Generally, if the cities are ranked from 1 (the largest) to \( n \) (the smallest), then the population of any city \( -k \) can be determined from the equation:

\[
P_k = P_1/k,
\]

where \( P_1 \) is the population of the largest city and \( P_k \) that of the city ranked \( k \). The steepness of the relationship between size and rank is incorporated by raising \( k \) to the power \( b \); that is, \( k^b \). No convincing explanations for the rule’s existence have been developed, however, nor for variations in the parameter \( b \) between regions (e.g. why the fifth-largest city is smaller, relative to the largest, in some places than it is elsewhere).

**raster** Raster is a GIS data structure akin to placing a regular grid over a study region and representing the geographical feature found in each grid cell numerically: for example, 1 = podsol, 2 = clay and so on. Rasters are associated with remote sensing, image processing and dynamic modelling, and are easily manipulated using map algebra (e.g. multiplying geographically corresponding cell values in two or more datasets) and neighbourhood functions (e.g. returning the sum of values in \( 3 \times 3 \) cell window). Rasters are simple but often voluminous. Patterns in the data are therefore compressed using run length encoding, quad-trees or wavelets.

**rational choice theory** A normative theory of individual decision-making, claiming that human action is motivated by getting the most for the least. On the one hand, individuals strive to achieve an unlimited set of ends where each end is associated with a different level of satisfaction or utility, but, on the other hand, they possess only a limited means to realize those ends. The role of the rationality...
postulate is to ensure that the best ends – that is, those yielding greatest individual satisfaction – are chosen given the constraint of limited means. Often couched in terms of the mathematics of constrained maximization, the problem of making the best choices is formally shown to reduce to a formal set of consistency requirements (Hahn and Hollis, 1979). Those requirements define rationality in the sense that if any one of them is contravened, the choice is not rational.

The historical antecedents of rational choice theory are with the British classical economists, but it is now most closely associated with their successor, NEO-CLASSICAL ECONOMICS, and a maverick strain of Marxism (ANALYTICAL MARXISM). Within economics, it is not just economic acts that are explained by rational choice. The University of Chicago, Nobel-Prize winning rational choice economist Gary Becker (1930–) uses the theory to explain all human acts from birth (the decision to have a child) to death (choosing suicide) and everything in between, including racial discrimination, committing crime, going to school, falling in love and filing for divorce (Becker, 1976). Nothing falls outside the ‘lore of calculated less or more’. The rational choice assumption is deployed across the social sciences, including sociology (rational individuals choose their social CLASS), political science (scenarios of GEOPOLITICAL brinkmanship modelled via GAME THEORY) and anthropology (cultures are ‘a collection of choice-making individuals’; Burling, 1962, p. 811).

Within HUMAN GEOGRAPHY, rational choice theory is most frequently found in ECONOMIC GEOGRAPHY and, in particular, in the formal LOCATION THEORY associated with REGIONAL SCIENCE. Its role is to impose a determinant order on spatial arrangements, allowing the theorist to make scientific claims to precision, exact inference and predictability.

There have been many criticisms of the rationality assumption, and they frequently focus on the unrealistic characteristics attributed to the rational actor (sometimes described in the gendered language of Homo economicus, or ‘rational economic man’): perfect knowledge; unyielding egoism; independent preferences; the ability and desire to maximize utility (minimize costs); and pursuit of a single goal (see SATISFYING BEHAVIOUR). Such criticisms are often moot, however, because the rationality postulate by its very construction is empirically untestable, a normative rather than a ‘positive’ theory, and therefore charges of unrealism have little purchase. More incisive are those criticisms that tackle the normative character of the postulate by arguing that it offers an unappealing vision of the world. Karl Marx (1818–83) (see Marx, 1976 [1867], ch. 6) satirizes rational choice by invoking the invidious character of ‘Mr Moneybags’, and the American institutional economist, Thorstein Veblen (1857–1929) (see Veblen, 1919, p. 73), makes it clear that ‘economic man’ is not even close to human: he is a ‘homogenous globule of desire . . . with neither antecedent nor consequent. He is an isolated, definitive human datum, in stable equilibrium except for the buffers of the impinging forces that displace him in one direction or another’ (see INSTITUTIONAL ECONOMICS). Another line of attack is to criticize the postulate’s intellectual origins and consistency. Mirowski (1989) does this by locating both the conceptual corpus of the rational actor and its associated mathematical techniques within the nineteenth-century physics of energetics. In other words, the rationality postulate was brought to social science via re-description: it is a METAPHOR. Apart from the fact that energetics itself was short-lived and quickly superseded, Mirowski argues that those economists who took up the metaphor never successfully transferred the core relations from physics to economics. The gap is of two different worlds, revealing a contradiction at the very heart of the project.

Barnes (1996, chs 2 and 3).

**realism** Realism comes in many forms, and realists vary widely in what they are prepared to be realist about. At its most general, realism entails belief in an external world that exists and acts independently of our knowledge of it or beliefs about it. The weakest form of realism simply asserts this belief, but is unspecific about *what* exists. A ‘common-sense realism’ asserts the existence of everyday objects, such as trees, stones or chairs. All of us are probably realists at this level. In the HUMANITIES, realism identifies a broad literary movement that identified ART in general, and LITERATURE in particular, with the truthful REPRESENTATION of the world through the meticulous and passionate observation of contemporary life. Its central arch spanned the mid-nineteenth and early twentieth centuries – from the novels of Gustave Flaubert (who in fact rejected the label) to those of Henry James – and some writers later re-described the project as a ‘naturalism’. Thus Émile Zola argued that in

---

**REALISM**

---

621
matters of cultural criticism and literary description ‘we must imitate the naturalists’. It is this possibility of NATURALISM that has propelled realism in PHILOSOPHY, SCIENCE and the social sciences (Bhaskar, 1998 [1979])

‘Scientific realism’ asserts the existence of various observable and unobservable entities of which it claims to be capable of giving the best representations. Many scientific realists subscribe to an ‘entity’ realism, which asserts the existence of many, well-established theoretical entities (various atomic particles, for example), but not necessarily to a ‘semantic’ realism, or belief in the truth of any one theory about such entities that correctly represents or mirrors ‘the way things really are’ (Hacking, 1983). There are also profound differences amongst scientific realists on notions of truth, reference, inference and explanation (Psillos, 1999). Matters are a little simpler in the social sciences in that a particular version of realism, critical realism, has become dominant and the focus of most debate. This is a version particularly associated with the work of Bhaskar (1986, 1989, 1998 [1979]) and Sayer (1992 [1984], 2000).

Early formulations of critical realism typically developed its main elements by asking what reality must be like to make the existence of science and its successes possible, which leads to a critique of the impoverished assumptions underlying EMPIRICISM or positivism. Critical realists reject the possibility of basing science on a ‘flat’ ontology of atomistic sense impressions. They make more complex ontological claims, distinguishing the empirical (events that we experience), the actual (events that happen whether we experience them or not) and the real (a deeper dimension of objects, structures and generative mechanisms that produce events).

Critical realists also reject a restricted, positivistic view of causality as the constant conjunction of observable events (a ‘regularity view’ of causation): ‘If A, then B’ (see LAW, SCIENTIFIC). Critical realists point out that the social sciences usually deal with open systems, rather than closed systems that can be artificially produced in a scientific laboratory. Although regularities are rare in such open systems, this does not mean that causes are not at work. Causes are thus best thought of as tendencies of objects, with distinctive powers in virtue of their essential structures, to act in certain ways. However, it is contingent whether and how those powers are activated in different combinations in different contexts to produce varying effects. Predictive success is thus difficult to achieve, but it may be possible to identify the underlying causal mechanisms beneath the flux of surface phenomena. The distinctive mode of inference to such mechanisms is called variously ABDUCTION, retrodiction or inference to the best explanation.

Powers are also often ‘emergent’ in the sense that the powers of objects or structures to produce effects are not reducible to those of their constituents (e.g. the powers of classes or groups may be more than the sum of the powers of their individual members). Reality is thus stratified in the sense that powers and mechanisms operative in one strata are not simply reducible to those of a lower strata.

Critical realists also make an important distinction between necessary and contingent properties or relations. Objects are necessarily or internally related if they are what they are by virtue of their relationships to each other (e.g. the relationship between landlords and tenants – each requires the other in order to be what it is). What we term ‘structures’ are made up of such networks of INTERNAL RELATIONS and define positions to be occupied by actors. However, it is often contingent who occupies these positions (landlords may be young or old, male or female etc.). ABSTRACTION is defined as the key procedure for identifying such structures by disentangling what are necessary from what are contingent relationships.

Critical realism also offers a distinctive perspective on familiar agency–structure dualisms that bedevil HUMAN GEOGRAPHY and, indeed, the humanities and social sciences more generally (see HUMAN AGENCY). Individual agency presupposes a social structure, and vice versa, but social structure and agency are ontologically distinct levels with different properties and causal powers (e.g. social structures are enabling and constraining; individuals have self-consciousness and reflexivity). Individuals may reproduce social structures through their everyday practices and understandings, but the ‘critical’ moment in critical realism lies in the belief that bringing underlying structures and their unconscious reproduction to the level of consciousness opens the way for emancipatory critique and social change.

Critical realism provides a philosophical framework for social science, but it does not prescribe a particular methodology. It is compatible with a range of QUALITATIVE TECHNIQUES and QUANTITATIVE TECHNIQUES that can aid the identification of causal structures, including HERMENEUTIC and interpretivist approaches.
Realism contends with various forms of anti-realism in the guise of POSTMODERNISM, PRAGMATISM and SOCIAL CONSTRUCTION. A key focus of debate concerns the meaningfulness of referring to a reality outside of the conceptual systems that we use to talk about it. From a pragmatist angle, Rorty (1979) argues that it is meaningless to talk about conceptual systems representing or ‘mirroring’ an extra-linguistic reality (see also REPRESENTATION). In the sociology of science, radical constructivists argue that reality is not something existing outside of scientific discourse, but is essentially a discursive construction (see SOCIAL CONSTRUCTION). Critical realists typically respond to such claims with the argument that although social reality may be highly concept-dependent, this does not mean that it is concept-determined in such an idealist way.

The division between realism and anti-realism runs through most areas of social science, including MARXISM and FEMINISM. However, the divisions should not be exaggerated. A ‘realistic constructivism’ would recognize both the ways in which scientific discourse is powerfully shaped by social interests and cultural values, and the constraining role of objective material realities. The relationship between discourse and reality is an interactive and reflexive one. At a more general level, Sayer (2000) has argued powerfully that critical realism occupies a ‘Third Way’ between the untenable extremes of empiricism on the one hand and postmodernism on the other. Certainly, critical realism was a vital intervention in the critique of SPATIAL SCIENCE and the refinement of MARXIST GEOGRAPHY in particular; it was also invoked to underwrite STRUCURATION THEORY. There was a lively debate about ‘the difference that space makes’ to EXPLANATION under the sign of critical realism (Sayer, 1985). Spatial relations are clearly important in analysing the contingent circumstances, the specific combinations of conditions under which causal powers might be realized, but several geographers argued that spatial relations also enter into the very constitution of the social structures involved (see SPACE). For a time, critical realism also held out the prospect of a plenary GEOGRAPHY, drawing human geography into a conversation with PHYSICAL GEOGRAPHY through a commitment to a common and recognizably ‘scientific’ programme. That was never achieved: by the time most physical geographers had become interested in realism, most human geographers had started to ask critical questions about its claims and consequences (e.g. Yeung, 1997), and many of them soon moved on to explore philosophies outside the confines of the philosophy of science, which were typically treated as resources rather than rule-books.

recognition The recognition of rights and needs tied to IDENTITY became a focus of much social movement activity in the 1980s and 1990s. This is known as identity politics, and is associated with a proliferation and fragmentation of SOCIAL MOVEMENTS around identities of GENDER, RACE, DISABILITY, ETHNICITY, SEXUALITY (amongst others), taken up by some STATES as state-sponsored MULTICULTURALISM. Criticisms of politics of recognition have come from across the political spectrum. MARXISTS have expressed concern about the dissolution of the unifying CLASS struggle. Within FEMINISM, Fraser and Honneth (2003) have drawn a dichotomy between politics of recognition and redistribution, arguing that the former neglects political economic issues and geopolitical developments, as well as simplifying and reifying group identities. (But see Butler (1998) for the argument that this binary misrepresents the complexity of calls for recognition insofar as they are typically intertwined with demands for redistribution.) In a different register, feminists such as Grosz (2005) advocate a politics of imperceptibility – a politics that unleashes unexpected events and encounters without being identified with a person, group or organization. Some European intellectuals criticize the politics of identity and difference within their national context as another instance of American cultural IMPERIALISM. Mitchell (2004b) considers how this last critique converges with a growing conservative backlash against ‘differentialism’.

Fraser (2000).

reconstruction Meaning ‘building again’, reconstruction is generally used in the DEVELOPMENT community to refer to a cluster of actions to restore or re-equip economies that previously were developed or in transition to sustainable economic growth. These are distinguished from actions aimed at stimulating growth and good governance in the poorest countries, those once described as underdeveloped. This distinction goes back at least as far
as the founding of the World Bank in 1944. The modern World Bank contains two institutions: the International Bank for Reconstruction and Development (IBRD) and the International Development Association (IDA). The IBRD made the first World Bank loan: $250 million to France in May 1947 for the reconstruction of its war-torn economy. The IBRD continues to be active in middle-income and transitional economies, providing loans for disaster relief purposes, in post-conflict situations and to post-socialist economies. Since 1991, The European Bank for Reconstruction and Development (EBRD) has joined the IBRD in central Europe and central Asia.

Reconstruction efforts sponsored by the IBRD and the EBRD have not been without their critics. Both institutions are committed to what they describe as democratization and market-led economic growth, and the agendas of good governance or the new public administration feature strongly in their self-descriptions. However, good governance was not at the top of the reconstruction agenda in Russia under President Yeltsin: the shock therapy recommended by Yeltsin’s advisers – including the Americans Jeffrey Sachs and David Lipton – led not only to price decontrol and currency convertibility, but also to the wholesale transfer of state assets to private monopolists. Sachs prefers to speak of ‘radical reforms’ rather than shock therapy (2005, p. 135) – but the shocking result of these measures (shocking, at any rate, to some mainstream economists) was a ruthless and often violent struggle for power, assets and territory. Far from providing an equitable restructuring of the economy of the former Soviet Union, reconstruction efforts have too often led to what David Harvey (2003b) calls ‘accumulation by dispossession’ (see also primitive accumulation). Hugely widening inequalities in income levels and healthcare provision have been just two results of reconstruction in Russia. Elsewhere, as in the Czech Republic and Poland, less dramatic reconstruction efforts have come closer to meeting the targets set by their governments and their international counterparts.

recreation Pursuits or activities (even inactivity) undertaken voluntarily outside paid employment for the primary purpose of pleasure, enjoyment and satisfaction. Recreational activities tend to be distinguished, in academic studies, from sports as not involving formal rules of competition. Such a division is also problematic, as sports may be undertaken non-competitively (e.g. one might play golf without competing), and other activities may involve more-or-less competitive elements with greater or lesser formalization (e.g. multi-player computer games contain highly formalised rules for competition, but would rarely be considered a sport). Recreational activities could be part of tourism, if occurring away from the place of domicile, or leisure, if occurring while at home, and the definitions of all the categories are very porous. A number of distinctions are often made regarding recreation’s orientation and organization.

Formal and informal recreations are often differentiated. Formal recreation involves activities that are structured and organized by an external body in prescribed times or places. This would thus include clubs, hobby societies and other organizations. Informal recreation refers to self-organized activities occurring at times and/or places of the individual’s own choosing. Trends to formalize more recreational activities have been linked to their commodification and the increasing sale of recreational goods – the production of which has become a major industry in the developed world. A further division often made is between passive and active recreation – playing in a band is active, while listening to one is passive. This distinction imports judgements freighted with normative values. A variety of policy initiatives around health have sought to encourage ‘active’ forms of recreation to increase fitness. Likewise, moral panics have often linked passive recreation to fears of youngster’s becoming ‘couch potatoes’ or otherwise harmed by the passive enjoyment of especially digital media. The assumption of passive consumption is contestable, since consumers may actively contribute to events and participate in numerous ways – transforming events or goods through their interpretations and reactions.

Geographies of recreation have tended to focus upon the effects on the environment and our relationship with it, and then the way in which spaces structure the availability and nature of recreational opportunities. For instance, the development of climbing fashions both discourses and tactile or haptic ways of knowing and valuing the environment (Lorimer and Lund, 2003; Taylor, 2006b). Alternatively, looking at environmental effects (such as
footpath erosion; see Liddle, 1997) or social impacts (such as contested claims and control) of recreation upon spaces might be a focus. Recreation can forge norms of appropriate conduct within spaces and lead to conflict, for instance, in parks or green spaces if different groups (in terms of age, ETHNICITY or SEXUALITY) have clashing recreational practices. A major strand of work has been disaggregating the social and physical factors affecting access to recreation in terms of income or DISABILITY or more hidden social factors. For instance, peri-urban woodland may be more-or-less physically accessible, but this may be compounded by fear of CRIME differentiating access by GENDER (Burgess, 1996). Work has looked to trends such as the commodification of recreation or the increasing spatial restrictions of CHILDREN's access to spaces of informal recreation in light of fears over their safety (Smith and Barker, 2001; Valentine, 2004; Department of Communities and Local Government, 2006). Recreation thus has to be seen as linked to the wider PRODUCTION OF SPACE, PRODUCTION OF NATURE and changing practices of consumption, where recent work has looked at recreational practices of dance, moving from studies of subcultures to discuss PERFORMANCE and BODY cultures, especially via NON-REPRESENTATIONAL THEORY. recycling A process that reuses the materials and energy components of an item to create another product. In most waste hierarchies, recycling sits below reducing CONSUMPTION, reusing an existing item and reprocessing, and above disposal. Although recycling uses ENERGY, it can reduce waste for disposal and the need for raw materials in production processes. Recycling was used during the two world wars, but not for environmental reasons. Although contemporary recycling may be undertaken solely for economic reasons (if recycled materials cost less than raw ones), it is usually represented as an environmental concern. Human geographers have investigated people's motivations for engaging in recycling activities (Barr, Ford and Gilg, 2003). PM

red-light districts While sex work has never been a solely urban phenomenon, it is in specific areas of towns and cities that it has been most visible. In most cases, these areas are particularly associated with female street PROSTITUTION, though in some instances, they are also characterized by an agglomeration of off-street work in the form of 'adult-oriented' businesses, sex clubs, theatres and peep shows. In some cities, these areas may coincide with spaces of male prostitution and gay venues, although the visibility of these in the LANDSCAPE has typically been less pronounced. The concentration of 'vice' and prostitution in specific areas has long fascinated urban geographers and sociologists, with the pioneering work of the CHICAGO SCHOOL of sociology including several detailed ETHNOGRAPHIES of the lifestyles of those occupying these areas of 'immorality' and deviance. More recent work has suggested that these areas cannot be understood merely as the outcome of supply and demand economics, but as the outcome of a complex interaction of moral codes, legal strictures and POLICING practices that encourage the containment of vice in INNER-CITY areas away from whiter, wealthier suburban populations (who, ironically, appear to be the principal clients of sex workers: Ashworth, White and Winchester, 1988; Hubbard, 1999). However, recent efforts to clean up vice areas, and the tendency for clients to contact sex workers via the INTERNET and mobile phone, means that red-light districts are becoming less numerous in Western cities (Sanchez, 2004). PH

redistribution A transfer of resources between groups or PLACES. Redistribution may be progressive (reducing INEQUALITY) or regressive (increasing inequality). Urban geographers emphasize the role of redistribution in the early formation of urban settlements. Harvey (1973), following the work of Karl Polanyi, argued that redistribution is one form of economic integration along with reciprocity and market exchange. Early urbanization is often assumed to have depended on the accumulation of an economic surplus, involving a shift away from reciprocity and towards redistribution (with resources being transferred from rural to urban areas).

Redistribution has been a core concern of WELFARE GEOGRAPHY with its focus on the unequal socio-spatial distribution of resources. The goal of reducing SOCIO-SPATIAL INEQUALITY was central to the development of the WELFARE STATE which seeks to mitigate the social inequality fostered by capitalist ACCUMULATION by providing free or subsidized services such as health care and education, and cash transfers such as unemployment benefits and old-age pensions. According to Keynesian economic theory, such transfers
had an economic as well as a moral rationale. It was thought that by helping to maintain the level of demand in the economy during periods of slow growth or recession, redistribution would reduce the risk of a major crisis of accumulation such as that associated with the stock market crash of 1929 (cf. FISCAL CRISIS). In practice, the extent of the redistribution provided by specific welfare states varied depending on their scope, the levels of benefits provided and the balance between universal provision and means-testing (Esping-Andersen, 1990). The rise of the New Right in the 1980s saw sustained political attacks in many high-income countries on the idea of progressive redistribution in line with the doctrines of NEO-LIBERAL economic policy. Neo-liberalism has been associated with a shift from the welfare to the workfare state, with the continuation of redistribution conditional on labour-market reform (Peck, 2001b). Work on redistribution within POLITICAL GEOGRAPHY has focused on the implications of the territorial restructuring of the state. For example, in devolved and federal systems, redistribution may involve ‘fiscal federalism’, in which the central (federal) level of the state arranges the transfer of resources between territorial units at lower levels. However, under NEO-LIBERALISM, a shift from managerial to entrepreneurial forms of urban GOVERNANCE has seen local agencies increasingly having to compete for a share of these redistributed surpluses (Harvey, 1989a). The forms of redistribution mentioned here mostly take place within the framework of the NATION-STATE, despite the fact that the greatest inequalities in income and wealth are between those living in high-income and low-income countries. In development geography, a concern with redistribution at the international scale is reflected in research on the politics of AID.

redistricting The redrawing of the boundaries of electoral districts (termed redistribution in the UK: see Rossiter, Johnston and Pattie, 1999). Redistricting can be manipulated to promote one party’s cause over another’s, as in MALAPPORTIONMENT and GERRYMANDERING. In the USA, the former was ruled unconstitutional in the 1960s, and redistricting is required after each decennial CENSUS (cf. RACIAL DISTRICTING). In most states, this is done by political parties, who deploy gerrymandering wherever possible to promote their cause. In the UK and some other countries, however, redistricting is undertaken by independent, non-partisan commissions, operating under legally defined rules. RJ

Handley (n.d.).

redlining A mortgage lenders’ practice of mapping high-risk neighbourhoods by encircling them with red lines. Lenders refuse to extend loans in these ‘redlined’ areas because of fears of default. Redlining discriminates against ethnic minority, low-income, female-headed and ‘non-traditional’ households because of the NEIGHBOURHOODS in which they live. The practice has been widely prohibited but still occurs informally (e.g. estate agents/realtors ‘steering’ clients into select neighbourhoods). Severe consequences ensue for cities, including vacancy, dereliction and neighbourhood decline (Darden, 1980). Recent research suggests that lending discrimination is contingent on a combination of the ‘RACE’ of prospective borrowers and the characteristics of neighbourhoods in which they hope to buy (Holloway, 1998).

Darden (1980).

reductionism The methodological presumption that complex phenomena or events can be explained by their reduction to simpler, more fundamental entities. For example, rather than to talk about human behaviour it is better to talk about genes, or even more fundamentally strands of DNA molecules. Or, rather than talk about lightning, it is better to speak about an electrical discharge, or more fundamentally the flow of electrons. Reductionism as a strategy is especially common in the natural sciences that strive to decompose phenomena or events into their most basic constituents or causes. For example, under ontological reductionism, the properties of matter are reduced to sub-atomic particles, quarks and leptons. Or, rather than talk about physical processes, the world, the universe and everything else are reduced to a single explanation, string theory.

Reductionism is also found in the social sciences, including HUMAN GEOGRAPHY. The exemplar is METHODOLOGICAL INDIVIDUALISM. In this case, the complexities of human behaviour are reduced to the single fundamental cause and typically cast as individual RATIONAL CHOICE. While it might appear that the diverse
decisions involved around, say, choosing where to live, or from which retailer to buy or where to site a new factory have nothing to do with one another, in reality, say methodological individualists, they all obey the same fundamental logic of rational decision-making. The facts and circumstances of each particular case can be eliminated because they are reducible to a more elementary set of formal axioms.

While reductionism as a methodological strategy is powerful and productive, seemingly yielding ever more secrets of nature and social life, it has been criticized on a number of grounds:

(1) The relationship among phenomena is holistic rather than reductionist. That is, the system as a whole determines how its parts behave. Reductionism therefore necessarily fails.

(2) Some entities, by their very nature – such as human motivations, emotions or sparks of creativity – are simply not divisible into constituent parts; there is always a 'ghost in the machine', to use Arthur Koestler's (1967) phrase. Humans cannot be reduced to Pavlovian salivating dogs or Skinnerian rats in a maze.

(3) Some phenomena or events are characterized by the property of emergence; that is, interactions of elements produce effects that cannot be predicted by examining the properties of those individual elements themselves (see also contextual effect and compositional theory).

(4) There is often something important in the original facts and setting that is lost when it is reduced to a different form. Translations are never perfect, and important contextual factors useful in explanation may be lost when reductionism is applied.

In human geography, reductionism was most strenuously applied during the period of the quantitative revolution and spatial science. Then the complexities of geographical landscapes were reduced to supposedly more fundamental entities, such as the postulates of geometry or the axioms of rational choice theory. Even after this period, reductionism remained important within the discipline. Radical geography, for example, was often characterized by economism; that is, the reduction of spatial relationships to economic ones. Historically, however, the discipline has always emphasized the importance of context, attempting to keep geographical facts intact rather than reducing them to something else. This sensibility has taken on greater theoretical momentum in the wake of post-structuralism and postmodernism, movements entering geography in the 1980s and associated with an explicitly anti-reductionist agenda. Critiques of reductionism, and attempts to develop non-reductionist research strategies, are found in feminist geography (Pratt, 2004), cultural geography and economic geography (Gibson-Graham, 2006).
Refugees

The term ‘refugee’ is widely used in popular culture, legal circles and humanitarian emergencies. Broadly speaking, it means people who have been involuntarily displaced from their homes and dispossessed of their livelihoods, normally without the protection of their own government. The media often refer to environmental refugees displaced from their land by soil erosion over time, economic refugees fleeing conditions of poverty in their home countries, or even refugees as people within the borders of their home country displaced by natural disasters (e.g. Hurricane Katrina in the American South in 2005).

In international humanitarian law, however, the term ‘refugee’ is more precise. It refers to people from one country who flee political persecution or violence to seek asylum in another country. The political persecution and exodus of the Protestant Huguenots from France during the late seventeenth century is often described as the first modern refugee movement. Since then, refugee movements have been related to post-colonial geographies (e.g. the partition of Pakistan from India in 1947), cold war geopolitics between rival superpowers and their allies (e.g. Cubans in the USA), geo-economic conflict related to land and resources, and wars of nationalism and independence.

Since the mass displacement of people in Europe during the Second World War, the concept of ‘refugee’ has taken on particular legal meanings. The 1945 United Nations Charter outlines a framework for the provision of political and legal protection to refugees, displaced persons and other vulnerable groups. In 1951, the Convention Relating to the Status of Refugees was drafted; it came into effect in 1954. Along with the 1967 Protocol, these legal instruments represent the pillars of international refugee law. The 1951 Convention definition includes anyone who ‘... as a result of events occurring before 1 January 1951 and owing to well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his[sic] nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence as a result of such events, is unable or, owing to such fear, is unwilling to return to it.’

While 147 nations are party to either the 1951 Convention or its 1967 Protocol (see below), it remains both explicitly and implicitly Eurocentric (see eurocentrism). From its conception, the Convention clearly demarcated geographical and historical limits. It was designed to apply to refugees in Europe displaced by events that occurred prior to 1951. The Convention is characterized by its Eurocentric focus and strategic conceptualization. The Convention definition of refugee is spatially coded as European. Substantively, its...
emphasis on persecution based on civil and political status as grounds for refugee status expresses the particular ideological debates of postwar European politics, particularly the perceived threats of communism and another Holocaust. In emphasizing civil and political rights, the Convention has had the effect of minimizing the importance of other rights. The European geographical focus and emphasis on civil and political rights in the Convention have generated an exclusionary geography of asylum that is the source of contentious contemporary debate (Hyndman, 2000).

The Convention definition implicitly creates a hierarchy of rights, privileging political and civil rights of protection from persecution over economic, cultural and social rights and scales of violence broader than individual persecution. The definition was also an expression of Cold War geopolitics, grounded in relational identities of communist East and capitalist West. Notwithstanding the objections of several delegates from developing countries faced with responsibility for their own refugee populations, the goal of the Western states was achieved by limiting the scope of mandatory international protection under the Convention to refugees whose flight was prompted by an event within Europe before 1951. While states might opt to extend protection to refugees from other parts of the world, the definition adopted was intended to distribute the European refugee burden without any binding obligation to reciprocate by way of the establishment of rights for, or the provision of assistance to, non-European refugees.

The 1967 Protocol Relating to the Status of Refugees amended the 1951 Convention. While it rescinded the spatial and temporal restrictions of the Convention by lifting the Europe-based, pre-1951 stipulations, it merely created equal access for all member nations to a legal instrument that remained substantively Eurocentric in focus. In Africa, the perceived inadequacy of this pair of legal instruments resulted in the drafting of a legally binding regional policy by the Organization for African Unity (OAU). The 1969 OAU Convention Governing the Specific Aspects of Refugee Problems in Africa not only broadened but also reformulated the definition of refugee. It included the 1951 Convention definition, but added the provision that generalized violence associated with colonialism and other kinds of aggression as grounds for seeking asylum.

In 1966, two legally binding human rights instruments were created to protect civil and political rights, on the one hand, and economic, social and cultural rights on the other. The International Covenant on Civil and Political Rights most closely expresses the emphasis of the Convention. It ensures respect for democratic principles and non-discrimination. The Covenant on Economic, Social and Cultural Rights includes provisions that are more applicable to developing countries than to highly industrialized ones, such as the right to food, shelter, and basic medical and educational services. While the first covenant applies to individuals, the second refers to particular groups of people.

In recent years, human geographers have generated a considerable body of work on the subject of refugees, probing the geopolitics that displace them (Le Billon, 2008), the governance/governmentality of international humanitarian assistance that assists refugees and manages their mobility (Hyndman, 2000), and the politics of resettlement in a new country (Black and Koser, 1999; Dahlman and O’Tuathail, 2005b). Those displaced by conflict and threats of persecution, but not across international borders, are referred to as internally displaced persons (IDPs). They are conceptually and politically related to refugees, but are still technically under the legal protection of their home governments as nationals (see Brun, 2003). Geographers have been particularly active in tracing refugee participation in transnational political, economic and social circuits that traverse international borders (Al-Ali and Koser, 2002; Bailey, Wright, Mountz and Miyares, 2002; Nolin, 2006). Another emerging research focus among geographers has been the tactics of exclusion employed by states of the global North [including Australia] to keep asylum seekers and other migrants at bay, away from their sovereign shores on which they could claim rights to seek asylum and other legal entitlements: references to the ‘externalization of asylum’ in Europe and the ‘Pacific Solution’ in Australia represent two cases in point (Hyndman and Mountz, 2008). Related to these tactics are geographies of containment in which displaced persons find themselves in ‘protracted refugee situations’ (PRS), spending years and sometimes decades in limbo, living in camps and without legal status. The United States Committee for Refugees and Immigrants (2008) calls this widespread phenomenon, which affects more than 8 million refugees, ‘refugee warehousing’. (See also CAMP; EXCEPTION, SPACE OF.)
REGIME OF ACCUMULATION

Suggested reading
UNHCR (2006).

regime of accumulation  A historically distinctive and relatively durable form of ACCUMULATION under CAPITALISM, based on complementary patterns of production and consumption, together with a supporting mode of regulation (an ensemble of organizational forms, networks, and institutions, rules, norms and patterns of conduct). Derived from French REGULATION THEORY, the concept of regimes of accumulation is most commonly associated with the analysis of FORDISM, the post-Second World War form of growth in North America and Western Europe, based on mass production/consumption and ‘Keynesian-welfarist’ modes of regulation (see Boyer, 1990; Jessop and Sum, 2006). Debates continue about the shape of the successor (post-1970s) regime, generically labelled POST-FORDISM.

Suggested reading

regime theory  An approach to politics that illustrates how different organizations interact in a dynamic POWER relationship under the umbrella of a larger project. The term has become influential in urban POLITICAL ECONOMY in the emphasis upon the management of interests shared between the PRIVATE AND PUBLIC SPHERES that coalesce into the government of an urban unit (Stone, 1989). The particular nature of the regime is a function of the continually changing combination of institutions, their individually changing goals, and the manner in which they influence each other to attain self-interest within a broader project. Urban regime theory highlights the dynamic power relationships between institutions within a regime and between competing regimes. Growth is the usual policy common denominator that brings the regime together.

Geographers have offered constructive critiques of urban regime theory. Ward (1996) highlighted the difficulty of applying the theory in contexts other than the USA, where it was developed, and called for consideration of the mechanisms which provoke institutions to form regimes rather than concentrating on how they are maintained. Ward (1996) and Hackworth (2000) critique the localism of initial regime theory, and call for consideration of the role of the STATE APPARATUS at larger scales, such as the federal STATE (see FEDERALISM) or even the European Union (see REGIONALISM).

Urban regime theory was a response to the economism of previous state theory, but as a result lacks consideration of how regimes become agents of capital ACCUMULATION (Hackworth, 2000). Consideration of environmental policy has drawn attention to why it is easier to build regimes around particular polices and not others (Gibbs and Jonas, 2000). NEO-LIBERAL policies have placed greater emphasis upon GOVERNANCE at the urban scale. Simultaneously, supra-state institutions such as the European Union have required consideration of how regimes forge links across scales.

Regime theory also applies to co-operation between states and non-governmental institutions tackling problems beyond the purview of one state. Environmental, trade and arms-control issues are examples around which a regime of legal connections and accepted norms and behaviours are constructed. Concentration upon the idea of a GLOBAL COMMONS and COMMON POOL RESOURCES and how they should be managed in an international system of sovereign states (see SOVEREIGNTY) underlies this approach. Such a regime involves a power dynamic in which the nature of the norms and goals, and the means of maintaining them, are continually negotiated between institutions with differential power capabilities. For example, Evans (2003) illustrates how the ASEAN Regional Forum has adapted to the increase in China’s economic and political capacities.

region  Most commonly used to designate: (a) an area or zone of indeterminate size on the surface of the Earth, whose diverse elements form a functional association; (b) one such region as part of a system of regions covering the GLOBE; or (c) a portion of one feature of the Earth, as in a particular CLIMATE region or economic region. The concept of the region, whichever meaning it has been given, has fallen in and out of favour, sometimes simultaneously.

The region has been subject to much examination as to its epistemological and ontological status (see EPISTEMOLOGY; ONTOLOGY). How are regions to be known and represented? Do regions exist in actuality? It is probably safe to say that most geographers who have dealt with these questions agree that regions are based on socially constructed generalizations about the world, that their delimitation and representation are artefactual but not purely fictions.
Few have disagreed, for example, that every pinpoint on the surface of the Earth is unique: the problem lies in looking past the uniqueness of mere points to say something of note about geographically bounded assemblages and distinctions and relations among assemblages (see also idographic). From this perspective, the artefactuality of regions is not that they are insubstantial (few geographers would claim that they are pure abstractions) so much as their definition demands disregarding certain details. The region in this sense is a ‘way of seeing’ that which exists, a device for organizing thought about the world; it is also, of course, the focus of regional geography.

The above ideas have given rise to a set of specific terms used to describe regions of different kinds (see Grigg, 1965). Formal or uniform regions are areas defined by one or more of the features that occur within them; for example, a region of Catalan-language speakers or a mining region in some part of the world where mining dominates the economy. Formal/uniform regions are interpretive devices that some geographers have used to make sense of a fundamentally heterogeneous world. There are no purely objective measures, therefore, that dictate what proportion of Catalan speakers in an area make it a Catalan-speaking region. Nor are there universally agreed criteria about what would define a mining region – The proportion of mine workers to non-mine workers? Income generated by mining compared with non-mining income? The land area covered by mines? Criteria are set, according to the purposes of designating such a mining (or Catalan-speaking) region at all. The functional or nodal region is a geographically delimited spatial system defined by the linkages binding particular phenomena in that area. Which phenomena? It depends on what kind of system we are interested in knowing about. The paradigmatic example is the urban region, in which there is a network of transactions (e.g. trading) centring on an urban core, or central place, and spreading out into and functionally incorporating an urban periphery or hinterland. (The functional region bears a resemblance to the core and periphery of world systems theory, and shares some of its criticisms too.) A number of other regional terms have been experimented with, especially in the first half of the twentieth century: single- and multiple-feature regions, natural regions, cultural regions, generic and specific regions, and so on. The genealogy of the region concept links it to related terms such as the French pays. Most of these terms are not used with particular favour any more, at least not in a disciplining defining sense, but the region nonetheless remains a core concept. Certainly, it has played a central role in suturing the different realms of human geography and physical geography. And it remains a generative force in the geographical imagination (Hart, 1982; Pudup, 1988; McGee, 1991; Paasi, 2003).

The region is also an embattled concept, as Grigg (1965) pointed out several decades ago. Features that may stand in geographical relation to each other rarely spatially co-vary exactly. The grouping of different phenomena together and the drawing of boundaries around them are therefore by no means obvious. (Although boundary mapping has spawned a great deal of research, using the quantifying tools of descriptive statistics, factor analysis, and most recently geographic information science.) There is the question too of whether the region is too static a concept, insufficiently attuned to change in the world, and whether regions have been understood too much in geographical isolation from the world. Grigg took these criticisms to mean that the region, especially its use by geography, needs always to be understood as a means to an end and not an end in itself (cf. Hartshorne, 1939). The point of ‘doing’ the region is not ultimately to divide the world into regions and rest content. It is rather, if one wishes, to engage in classifying and modelling geographical phenomena so as to generate questions about their variability and functioning with respect to other phenomena. Indeed, for Grigg, whose essay appeared in a seminal text of the quantitative revolution, the region is a model.

In the 1980s and 1990s, some geographers proposed to solve the problem of the region by reframing the terms of study and ushering in a ‘new regional geography’ (e.g. Pudup, 1988; Thrift, 1994b; cf. Gregory, 1982). Spurred on by an interest in structuration theory, social theory, political economy and locality studies, the goal was to see the region as a medium and outcome of social practices and relations of power that are operative at multiple spatial and temporal scales, among which the region might serve as a kind of fix. There was also in the new regional geography an explicit critique of an insufficiently spatialized social theory and political economy. There has been some debate as to whether the new regional geography misconstrued the concept and uses of the region during its heyday before the
Second World War, and specifically whether regional geography was an *atheoretical* geography (see Holmen, 1995). For now, debate seems to have settled down.

Gregory (1982); Grigg (1965); Hart (1982); Pudup (1988).

**regional alliance** An agreement between a group of neighbouring political units facilitating cross-border co-operation. The term is particularly identified with security co-operation between states. NATO is the strongest such alliance, with the commitment that an attack on any one of the member states by an external aggressor is deemed as an attack against all of them. During the Cold War, the USA (NATO, SEATO, CENTO) and the Soviet Union (Warsaw Pact) created rival regional alliances. Since the terrorist attacks of 11 September 2001 (see terrorism), the USA has attempted to forge alliances with many countries, but none of the recent efforts have the intensity and breadth of the Cold War era. Post-Cold War changes and the break-up of the Soviet Union have catalysed new regional initiatives to facilitate trade and economic development (Pinnick, 2005) as states balance the promotion of economic interaction with cross-border security concerns, and manage security concerns no longer viewed as part of the Cold War conflict (McNulty, 1999). The increased pressure upon localities to be attractive to global investment has also fostered local regional alliances to build transport and other forms of economic infrastructure that can not only enhance economic growth but also facilitate peace across international borders (Newman, 2005). The current geopolitical context shows that regional security alliances are in flux as NATO expands its border eastwards to include former Warsaw Pact members (Oas, 2005), but at the same time the European Union builds its own security apparatus that at the moment is deemed to complement NATO, but could succeed it.

**regional cycles** Fluctuations or cyclical waves in the level of a variable in a region. Techniques and models for analysing regional cycles have been applied to both regional economic activity and to epidemics and the modelling of disease. Cycles in economic activity, usually measured by industrial output or unemployment rates, can be very long-term, as with *Kondratieff cycles*, or shorter-term, reflecting both seasonal variations in the demand for labour and the regional impact of national business cycles of expansion and recession. Some descriptive studies of regional cycles were undertaken in the early years of regional science, but more recent work has focused on modelling the cycles. Economists have built regional (e.g. the State of California) and multi-regional (e.g. all the regions of France) econometric models. These relate macroeconomic variables of output, expenditure and employment at the regional level to each other, and to national economic and policy variables. Such models now exist for many countries and regions. A second approach, mainly by geographers, has studied the spatial diffusion of regional cycles, tracing the timing and cyclical amplitude for different cities and regions.

Glickman (1997); King and Clark (1978).

**regional geography** The study of the variable character of places in the world, usually with an emphasis on their human geography. Knowledge of world regional geography is often seen as essential to general education and a specifically ‘geographical literacy’, which is why it forms a mainstay of introductory survey courses in many universities. Critics frequently complain that such courses are little more than a fact-driven whirlwind tour, but regional geography has a long intellectual history and, like the larger discipline, its role, objectives and methods have changed over time. The authors of the better textbooks are very well aware of these considerations, and sensitive to the pedagogical possibilities they allow and the responsibilities they impose (e.g. Bradshaw, Dymond, White and Chacko, 2005; de Blij and Muller, 2007).

Regional geography is usually traced back to Strabo’s conception of chorography as the disciplined description of the parts of the Earth. As late as the seventeenth century, this continued to provide the model for what in early modern Europe was called *Special Geography*, founded – as Bernard Varenius (1622–50) put it – ‘upon the experience and observations of those who have described the several countries’. Studies such as these may have contributed to a privileged, civic education, but they had larger purposes too. Just as Strabo’s chorography informed the administration of the Roman Empire, so did Varenius recognize that *Special Geography* had a particular significance for both ‘statecraft’ and the world-
empire of merchant CAPITALISM centred on the Dutch Republic and the city of Amsterdam. And both were haunted by their epistemological other: by the mathematical–locational corpus of Ptolemy’s Geography and Varenius’ own ‘General Geography’. All three features reappear in the subsequent history of regional geography in Europe and North America: the production and circulation of regional descriptions for public audiences, the strategic application of regional intelligence, and the formalization of a spatial scientific dual to regional geography.

In the eighteenth century, a European GEOGRAPHICAL IMAGINARY treated ‘EUROPE’ as the master-architect of an intellectual grid, a sort of semiotic square (see table), in which ‘AFRICA’, ‘ASIA’ and ‘AMERICA’ were placed in distinctive and subordinate positions within a matrix of difference (Gregory, 1999b). These four cardinal orientations structured the production of regional stereotypes. These were in the main the products of European projects of EXPLORATION, whose results were circulated to a wider public through exhibitions, illustrations and published accounts of travel. In fact, TRAVEL–WRITING has been a vital source for the production of regions as bounded spaces possessing some sort of unity that makes them distinctive, ‘special’ or unique. Within this genre, regions are typically represented as distinctive zones set off from other regions, whose essential nature – at once a matter of ‘identity’ and ‘authenticity’ – is conveyed through both a narrativization of space (plotting the author’s tracks) and an aestheticization of LANDSCAPE (producing a word-picture). Their IMAGINATIVE GEOGRAPHIES become sedimented over time, so much so that many contemporary travel writings by European and North American authors continue to sustain an elaborate textualization of regions as zones that re-inscribe eighteenth- and nineteenth-century stereotypes: ‘the tropics’ as a zone of excess, of primeval nature and human ABJEC­tion or plenitude and freedom (see TROPICALITY); ‘the Orient’ as a liminal zone of mystery and danger, eroticism and TRANSGRESSION (see ORIENTALISM); and ‘the Arctic’ as a limit-zone of solitude, silence and extremity (Lutz and Collins, 1993; Holland and Huggan, 1999). These are not (and never were) innocent representations, and similar ways of dividing up the world into regions and identifying their supposedly characteristic natures are activated within other public discourses, including the signature images associated by travel companies with places such as ‘India’ or ‘China’, the stereotypes of ‘the MIDDLE EAST’ invoked by European and American media organizations, and the partitional vocabularies of ‘BALKANIZATION’, ENCLAVES and dominoes (see DOMINO THEORY) mobilized by contemporary GEOPOLITICS.

In the course of the nineteenth and early twentieth centuries, the academic discipline of GEOGRAPHY was drawn to the REGION as its central object of study. ‘Object’ is exactly the word: the region was seen as one of the basic ‘building-blocks’ of geographical enquiry. This METAPHOR clearly conveys the common sense of regionalization as both partitional (the world can be exhaustively divided into bounded spaces) and aggregative (these spaces can be fitted together to form a larger totality). This sensibility applied both to traditional regional geography and to the successor projects of SPATIAL SCIENCE. In the regional monographs written by French geographer Paul Vidal de le Blache at the turn of the nineteenth and twentieth centuries, for example, the regions (pays) of France owed their identity (or ‘personality’) to the local CULTURES that impressed themselves on the local landscapes (differentiation) and to their connections with other places within the system of the French NATION (circulation; see also AREAL DIFFERENTIATION). In the austere lexicon of LOCATIONAL ANALYSIS, regions were seen as cells within spatial grids. Thus Grigg (1965) argued that regionalization is similar to classification, and his account of the logic of regional taxonomy provided the basis for a series of formal region-building ALGORITHMS in which regions were treated as combinatorial, assignment or districting problems: in effect, as the product of purely technical procedures. To Haggett, Cliff and Frey (1977), therefore, the region was simply ‘one of the most logical and satisfactory ways of organizing geographical information’ (see also CLASSIFICATION AND REGIONALIZATION).

The regional-descriptive and the mathematical–locational impulses were both channelled into the production of regional knowledges during and after the Second World War. Indeed, one geographer claimed that ‘World
Dickinson (1947) proposed a focus on the city or regional systems in which functional regions placed great demands on the spatial science. In the first place, they both regional geography had little in common with its physical landscape (see paysan, paysage, pays between culture, landscape and region – Vidal de la Blache had assumed an intimacy of both cultural and physical landscapes. Regional geography sought to convey descriptive and the mathematical–statistical methods and models, and represented regions as little more than convenient ordering devices within an overwhelmingly abstract space. In the first place, they both placed a premium on fieldwork as the experimental ground for evocative prose, so much so that Hart (1982) hailed regional geography as ‘the highest form of the geographer’s art’. How many regional monographs ever reached ‘the highest form of the geographer’s art’. How many regional monographs ever reached those commanding heights remains an open question, but Lewis (1985) observed that even if few academic geographers were trained as painters or poets, there was no reason to boast about it. Spatial science found its own aesthetic in the elegance of formal analytical methods and models, and represented regions as little more than convenient ordering devices within an overwhelmingly abstract space. In the second place, travel writing and traditional regional geography sought to convey descriptions of both cultural and physical landscapes. Vidal de la Blache had assumed an intimacy between culture, landscape and region – between paysan, paysage and pays in rural France – that placed great demands on the sensibilities of the geographer. In contrast, spatial science was largely preoccupied with functional regions or regional systems in which the central organizing principle was to be found within a society largely severed from its physical landscape (see nodal region). After the Second World War, for example, Dickinson (1947) proposed a focus on the city region as ‘an area of interrelated activities, kindred interests and common organizations, brought into being through the medium of the routes which bind it to urban centres’, and ten years later Philbrick (1957) argued that ‘the functional organization of human occupation in area’ should be analysed ‘independent of the natural environment’ (emphasis added) through a series of intrinsically geometric concepts: focality, localization, interconnection and discontinuity. These proposals formed a springboard for the subsequent leap towards the formal spatial analysis of regions as ‘open systems’ (Haggett, 1965, pp. 18–19).

Running in the depths of these different literatures and transgressing the boundaries they drew around regions was a sub-text that threatened to interrupt and prise open their compartments and closures. The journeys of explorers and traveller-writers, the capillary circulations that coursed through regions and the thematization of regions as open systems all spoke to the porosity of regional formations (the networks of connection between places; cf. contrapuntal geographies; power geometry) and to the poetics of regional description (the conventional, ‘constructed’ nature of boundary delimitation). These twin issues have since received explicit and substantial critical attention.

Even at its height, regional geography was criticized for its closures. Vidal de la Blache’s celebrated Tableau de la géographie de la France (1903) was a portrait – some said a landscape painting – of the individual regions of pre-revolutionary France, produced through a method that critics said had little purchase on the post-revolutionary world. ‘The region is an eighteenth-century concept’, Kimble (1951) declared, whereas in the modern world ‘it is the links in landscapes . . . rather than the breaks’ that matter. Similarly, Wrigley (1965) argued that the intimacy of the bonds between ‘culture’ and ‘nature’ celebrated by regional geography was ‘admirably suited to the historical geography of Europe before the industrial revolution’, but ‘with the final disappearance of the old, local, rural, largely self-sufficient way of life the centrality of regional work to geography has been permanently affected.’ These twin objections were marked both by their European origins and a superficial understanding of industrialization and the dynamics of the capitalist space-economy (which produces regional differentiations rather than erasing them: see Langton, 1984; Storper and Walker, 1989). In fact, Vidal’s later account of France de l’est (1917) was an attempt to wire
the industrialization of Alsace-Lorraine to the wider geopolitical structures of France as a whole and, *en passant*, to challenge the legitimacy of its post-1871 occupation by Germany.

Recent attempts to situate regional formations and transformations as constellations or condensations within more extensive networks have been far more attentive to such concerns and in the 1980s and 1990s many of them were given a considerable fillip by *world-systems theory* and the analysis of the capitalist world-economy (see, e.g., Agnew, 1987b; Dixon, 1991; Becker and Egler, 1992). These projects were distinguished by a much greater sense of historicity – of place and region as historically contingent process (Pred, 1984; Gilbert 1988) – which in turn made the ‘bounded spaces’ and ‘building blocks’ of conventional regional genres seem much less solid. To talk in this way is not merely to invoke Marx’s description of capitalist *modernity* as a world in which ‘all that is solid melts into air’, important though that is, because the tensions between ‘fixity’ and ‘motion’ that spasmodically interrupt and restructure regional formations are not the exclusive preserve of *capitalism*, and are hence not contained by its history alone. Our present understanding of regions suggests that they have never been closed, cellular, bounded spaces: indeed, much of ‘traditional’ regional geography may turn out to have been about inventing a ‘traditional’ world of supposedly immobile, introspective and irredeemably localized cultures. Many anthropologists, geographers, historians and others now accept that non-capitalist worlds have also always been actively engaged in other worlds, and that they have also always been constituted through their involvement in trans-local and trans-regional networks.

In order to develop historical geographies of regional (trans)formation that are open to these possibilities, it is not enough to locate regions within progressively larger global frameworks or to identify the ‘regional’ as one level within an interlocking system of different *scales*. One of the persistent difficulties of such approaches is that regions become products of processes that are located ‘on the outside’ – in the absolute spaces of the containing frameworks and coordinate systems – so that regions become surfaces that merely register the impacts of *globalization*, of successive rounds of capital *accumulation* or the *division of labour*, or of cycles of *time-space compression* that are seen as enframing them. Against these ways of figuring the world, many scholars now argue that such processes are also ‘on the inside’ – indeed, that the demarcations between ‘outside’ and ‘inside’ are deeply problematic and made more so by what Hardt and Negri (2000, pp. 194–5) call ‘Empire’, where ‘the modern dialectic of inside and outside has been replaced by a play of degrees and intensities, of hybridities and artificiality’. Whatever one makes of this particular thesis, there is a broad consensus within human geography that regional formations are more or less impermanent condensations of institutions and objects, people and practices that are intimately involved in the operation and outcome of local, trans-local and trans-regional processes. For much the same reason, even though the ‘regional’ has constantly been hypostatized as the quintessential scale of geographical analysis, many writers have become much more attentive to the ways in which these scalar distinctions have been historically produced. It is through these productions, at once material and discursive, that regional structures have become sedimented in imaginative geographies, in material landscapes, and in *public policy*.

The theorization of regional formations as partial, porous, hybrid condensations of entangled networks between human and non-human actants, each of different spans and with inconstant geometries, raises difficult questions of *representation*. How are these ideas and concepts to be redeemed in the fabrication of regional accounts? Part of the problem concerns the need to find ways of conveying these theoretical constructs in empirical solution: as Pudup (1988) observed, ‘Anyone trying to mesh theory with empirical description [in regional geography] soon learns that movement among abstract concepts and empirical description is like performing ballet on a bed of quicksand’ (see also Sayer, 1989). To some writers, the metaphor of dance subsequently seemed peculiarly appropriate: one implication of *non-representational theory* is that all human geographies need to become much more physically sensuous, much more expressive in their poetics. In the specific case of regional geography, there is clearly much to learn from careful, critical readings of imaginative *literature*, *film* and video, and from contemporary travel accounts that have tried to find the terms for the complex interpenetrations of cultures: what Iyer (1989) epigrammatically described as ‘*Video night in Kathmandu*’ (cf. *transculturation*). In doing so, authors have wrestled with some of the same demons that haunted traditional regional geography, and
above all with a sense of ‘belatedness’ – a sort of
elegy for the world we have lost – that, on
occasion, too readily modulates into what
Rosaldo (1989) calls ‘imperial nostalgia’
whereby ‘people mourn the passing of what
they themselves have transformed’.

These issues are thus not confined to
regional geography, and they admit of no easy
solution. They also indicate the importance of
developing an ETHICS of regional description
and analysis capable of addressing both the
subjects and the audiences of such accounts.
The authors of regional geographies have
an obligation to respond to questions of
adequacy, accountability and authorization:
What are their responsibilities to the people
whose lives they write about? And they also
have an obligation to convey places, regions
and landscapes as something more than the
lifeless parade of categories or the endless
tabulations of statistics that loom so large in
many textbooks of regional geography. There
is a need to represent places and their inhab-
itants in ways that compel their audiences to
care about them: which is why the ‘openness’
of regions – the sense of trans-local and trans-
regional engagement and interconnection – is
important not only intellectually but also pol-
tically. Whatever else regional geography is
about, it surely ought to be about disclosing
our involvement with the lives and needs of
distant strangers.

regional policy Policy concerned both with
the regional (normally thought of as sub-
national) constitution and effectivity of ECON-
OMY, SOCIETY, CULTURE and polity, and with
the economic, social and cultural constitution
and effectivity of regions. These two aspects of
policy are not binaries: they are mutually con-
stitutive of regional policy. However, although
always influentially co-present in policy initi-
atation, design and implementation, their rela-
tive significance varies across space and time.

As objects of policy, REGIONS are subjected
to attempted policy-led transformations
designed to ameliorate UNEVEN DEVELOPMENT
for reasons of SOCIAL JUSTICE, welfare and
economic efficiency. Whilst contemporary
emphases in regional policy are increasingly
preoccupied with a singular concern for
ECONOMIC GROWTH, these motives are not
mutually exclusive. Regional policy is rarely
purely redistributive. It is intended to be
transformative. Thus it may, for example,
involve bringing work to (unemployed/low-
productivity) workers or attempt to address
the uneven distribution of cultural facilities
(e.g. symphony orchestras, art galleries and
theatres) or the regional availability of educa-
tional facilities (such as university disciplines,
for example). Such policies are usually driven
and financed from outside the region – albeit
often with regional participation – by national
or supra-national STATE bodies. In terms of
policies attempting to address issues of welfare
and social justice, what is inescapable here is
fiscal redistribution and effort to direct the
geographical trajectories of the circuits of
value that make up economic geographies.
And, in addition, national macro-economic
policies are rarely region-neutral – as may be
illustrated, for example, in claims for and
against public expenditure in south-east
England and in debates around the political
and fiscal separation of the north from the
south of Italy – whilst a range of policies (e.g.
labour market policy, transport policy and
welfare policies) have pronounced regional
consequences even if articulated at the level
of the nation or supra-national state.

Alternatively, regional policy may stress
regional responsibilities for addressing UNEVEN
DEVELOPMENT through regionally induced
supply-side transformations – involving
regional training, learning and innovation,
for example – designed to increase regional
economic efficiency, PRODUCTIVITY and dyna-
mism. It thereby places responsibility for these
transformations on local workers and firms –
albeit with some support and encouragement
(both positive and negative) of various kinds.
Local responsibilities may also be emphasized
through competitive bidding processes for
major international events such as the
Olympic Games, for licences to open and run
casinos, or for resources to finance cultural
renovation or the upgrading of institutions of
higher education, or for investment in new
or upgraded infrastructure – to encourage
regional capacities such as public transport or
cycling for a post-carbon age.

The claimed economic, political and social
formative role of regions underlies their roles
as subjects of policy. Economically, claims for
the significance of regional context and prox-
imity in enabling the intense development of a
range of traded and untraded interdependencies
and the emergent role of TRUST in cutting the
TRANSACTION COSTS of economic activity, as
well as notions of ‘buzz’ based around per-
sonal and face-to-face contact in enhancing
the effectiveness of circuits of value and the incorporation of a wide range of local influences – including local institutions – enabling dynamic processes of learning and innovation, reveal the significance of regions in constituting productive circuits of value and hence in constituting economic geographies (cf. CLUSTER). Here, policy is based on the assumption of the critical significance of the regions in forming economic geographies and of creating the conditions of existence for the enhancement of regionally based processes of economic growth.

However, whilst such CONTEXTUAL EFFECTS are doubtless formatively important, it is easy to downplay the critical and inescapable – and hence deeply formative – material imperatives of economies and, more especially, the distinctive material objectives and dynamic geographies of CAPITALIST circuits of value in shaping regional economic geographies. Accounts of regional development focused on the geographies of global production networks held down in place by various contextual forces – including regional policy – begin to capture the essential DIALECTIC between these two sets of forces (material and contextual) that shape the economic fortune of regions.

Politically, strongly developed notions of cultural and political identity – as revealed, for example in contested relations between Macedonia and the Greek provinces of Makedonia, or in Basque and Catalonian claims for independence in Spain, and in Brittany or Corsica in France and the Chiapas in Mexico – point again to the formative significance of regions as the subjects of regional policy in wider political and cultural relations. Policy here is devoted primarily to the containment and regulation of regional aspirations. However, the geography of regional awareness, IDENTITY and imagination is itself unevenly developed.

A number of overarching issues surround the design and conduct of regional policy. First, what is the region? Territories are often contrasted to relational notions of regions. Territorial notions view regions in absolute terms – as containers – or in relative terms – as formatively interacting containers. Proponents of the latter, relational view argue that regions are porous, open and fluid. They are shaped by relations of all sorts operating in a multi-scalar universe in which SCALES themselves are socially constructed, if often powerfully defended in political terms. In this view, regions are as much a product of external relations (like flows of capital and ideas) as of those internal relations (such as the relations between people and NATURE that were the focus of classical REGIONAL GEOGRAPHY).

In fact, however, both notions of region are mutually constitutive. Territories are themselves made up of a variety of NETWORKS, and the ‘internal’ characteristics of territories are simply the outcome of the historical geographies of relational links within and beyond the region. In this way, time and path dependency (but not determinacy) comes to arbitrate between TERRITORY and relationality in regional formation. At the same time, territories and regions are constructed by BOUNDARY marking (often involving powerful relations of domination and inducement) and by influential centres of calculation operating within and beyond the state (e.g. in academia) constructing statistical definitions and accounts of them. In such ways, regions may be invented in much the same way that national economies are invented through the technologies of their description and analysis.

Thus the question of who speaks for the region – who has voice in identifying the region and regional policy – becomes critically important. Given the widespread interest in the region as a long-constituted expression of distinctive and integrative social identity, it is all too easy (or convenient) in policy formulation and assessment to assume a unity of purpose and a homogeneity in regions in which diversity and contestation may be inherent. Politico-religious and class-based regional conflicts such as those in Northern Ireland during the ‘troubles’, or class-based conflicts of interests in regions such as the North East of England, with a long historical geography of social development based on deeply held and long-standing CLASS divisions, reveal how simplistic such assumptions may be. And, of course, speaking for the region may emanate from outside the region (e.g. from national or supra-national interests) at least as much as from within. Voice – and who has it – becomes even more significant in regions with clear aspirations to autonomy or independence.

Related to such questions around the construction of regional policy is the whole complex of issues surrounding notions of GOVERNMENTALITY and the ongoing (or not) legitimacy of the authority to govern. With the spread of DEVOLUTION around the world, the region and regional policy are deeply implicated in the emergence and negotiation of multi-level patterns of GOVERNANCE. This involves the legitimacy of different levels of
government, and the distribution of resources and responsibilities between them. Such changes and the debates around them are closely related to changing notions of government – including the move from the political representation of individuals and places to the economic, social, cultural and political responsibility of individuals and places – as the distinctions between the state, civil society and economy are dissolved and recombined in the attempt to maintain political legitimacy in the face of such changes and the globalizing geographies (see globalization) that shape them. But beyond this, questions of governance open up the questions of how who gets to speak for regions and how regional policy gets to take place. Central here is the issue of expertise and the establishment of policy norms and target-setting, which enables governmental action on regions and the possibility of the emergence of creative capacity within regions. However, just as such capacities (or the lack of them) do not guarantee ‘success’ – whoever may define it – neither does it enhance the possibilities of more participatory forms of democracy. This is, perhaps, especially true of regions long suffering from economic decline and the withering of circuits of value. Hence the political issue of the relations and modalities of power between regional and national/supra-national governance becomes central if the question of uneven development is to be addressed head-on in policy formulation. But, of course, this does not mean that regional economic policies, for example, will be based on the pursuit of social justice rather than of economic effectiveness.

Such norms and targets raise a fourth overarching issue concerning the objectives of regional policies. For example, economic policies are increasingly narrowly formatted around issues of competitiveness and productivity as measured through profitability. Not only does this framing ignore a range of issues such as the work that takes place – and goes largely unmeasured – beyond the capitalist economy, as well as the diverse norms and social relations involved in materially effective circuits of value, including – but not reducible to – the social economy lying outside the mainstream, but it also tends towards reductive notions of processes such as innovation defined in terms merely of contributions to profitability.

Finally, the long-standing significance of the region as a focus of distinctive identities and even loyalties – and this not least as a consequence of the crucial role of historical economic geographies in shaping a sense of belonging, albeit contested and conflicting belonging – combines in a potentially problematic fashion with the notion of the region as a formative economic, social and political entity and a constructed object of policy in which regional responsibility for development is stressed. Under these circumstances, in which the region is perceived as a representation of meaning and practice, blame is all too readily attached to the victim. However, this tendency may be countered from the perspective of geographical political economy. This way of understanding is capable of recognizing not only the role of people in making their own geographies (if not necessarily under the conditions and constraints that they would choose) and the genuine material constraints on regional development (which mark the economic, political, cultural and geographical limits of regional responsibilities for the construction of geographies), but the political possibilities in the pursuit of policies capable of sustaining locally distinctive as well as materially, socially, politically and culturally effective regions.

Regional science
A hybrid discipline originating in the early 1950s that combined neoclassical economics and quantitative methods to analyse spatial issues in economics, human geography and planning. Regional science was the vision of a single man, the American economist Walter Isard (1919–). Isard roundly criticized the assumption of the a-spatial ‘pin-head’ economy found in standard economic theory, and provided an alternative version based upon location theory, and in 1954 he convened the first meeting of the Regional Science Association in Detroit. Partly because of Isard’s indefatigable energy, and partly because of the movement’s fortuitous emergence in a period of significant American regional and urban growth, regional science rapidly expanded, increasing its membership, forming new university departments, inaugurating journals such as the Proceedings of the Regional Science Association and then, in 1958, the
Journal of Regional Science, initiating international branches (Europe in 1961, Asia in 1963) and attracting attention from cognate disciplines. One of those was economic geography, and for a period in the 1960s – the halcyon years of the quantitative revolution and spatial science – the agendas of the two were symbiotically linked. The 1970s began a reversal of fortunes, as former allies such as economic geography increasingly deserted regional science, its practitioners caught up in the critique of spatial science, the concomitant advance of political economy through the sub-discipline, and the emergence of an avowedly radical geography. From the 1990s, competitors for the same intellectual (and artificial) turf cultivated by regional science emerged, such as the new economic geography, and university administrators turned sour (Isard’s original Regional Science Department at the University of Pennsylvania was closed in 1994–5). Against the backdrop of two decades of intellectual and then institutional assault, regional science moved to the margins of human geography and the social sciences more generally.

Regionalism A term referring to both a form of political identity and sub-national economic integration. Attempts have been made to clarify the definition to delineate the ‘old’ regionalism of a political identity seeking autonomy or separation from the state (see secession) and the ‘new’ regionalism of economic integration at the sub-national scale, which may include governmental administrative functions (Witt, 2005). Regionalism is seen as a theoretical and methodological vehicle to analyse new forms of governance within the context of neo-liberal policies (see neo-liberalism) and supra-state institutions (O’Loughlin, 1996). Further clarification is provided by Jones and MacLeod (2004), who distinguish between regional spaces and spaces of regionalism. Regional spaces are regional economic geographies of technological spillovers and inter-firm agglomeration that produce a regional clustering of economic assets (cf. cluster). Spaces of regionalism are the ‘(re)assertion of national and regional claims to citizenship, insurgent forms of political mobilization and cultural expression and the formation of new contours of territorial government’ (Jones and MacLeod, 2004, p. 435).

As governments restructure under the pressures of neo-liberalism and globalization, the politics of regionalism often does not distinguish between the regional economic policies and regional political identity. As Paasi (2003) has pointed out, there is an important difference between the identity of a region, or the classification of a space by government and other agencies, and the regional consciousness of individuals, or the degree and form of political regional attachment. Recent identification of a ‘resurgence of the regions’ refers to both the creation of regional economic spaces attempting to capture global investment by touting a regional comparative advantage as well as the political movements, such as Lega Nord in Italy, dissatisfied with membership in the existing state. Jones and MacLeod (2004) caution social scientists and policy-makers that there is no necessary relationship between regional economic spaces and regional political identity, which may cause problems for governments and the European Union promoting regional policies. Furthermore, both regional spaces and spaces of regionalism occur at various scales, and must be viewed as a political process involving conflict and negotiation rather than fixed political geographical entities. (See also regional policy.)

Regression A statistical relationship between a dependent variable and one or more independent variables. The standard technique for regression analysis fits a straight-line trend through a scatter of points (as shown in the figure), with the line placed to minimize the sum of the (squared) distances between it and the individual points. In the formula for a simple regression (i.e. with one independent variable),

\[ Y = a + bX \pm e, \]

Y is the dependent variable (shown on the vertical axis); X is the independent variable (shown on the horizontal axis); a is the intercept or constant term (i.e. the value of Y when X equals zero); b is the regression coefficient (i.e. the slope of the relationship, indicating the change in Y for each unit change in X); and e is the error term, indicating the degree of scatter of points around the line. The closer the fit of the line to all of the points, the larger the associated correlation.
Multiple regression equations have the form

\[ Y = a + b_1X_1 + b_2X_2 + \ldots + b_nX_n + \epsilon, \]

in which each of the independent variables \((X_1, X_2, \ldots, X_n)\) has an associated partial regression coefficient \((b_1, b_2, \ldots)\) indicating the amount of change in \(Y\) for each unit change in the relevant \(X\) variable, assuming no change in any other \(X\). (See also GENERAL LINEAR MODEL; GEOGRAPHICALLY WEIGHTED REGRESSION; LOGIT REGRESSION MODELS; MULTI-LEVEL MODELLING; POISSON REGRESSION.)

regulation theory  A branch of contemporary political-economic theory, influenced by MARXISM, which seeks to explain the growth, crisis and transformation of CAPITALISM, with particular reference to historically, geographically and institutionally specific conditions. Regulation theorists balance a Marxian emphasis on the structures, ‘laws of motion’ and incipient CRISIS tendencies of capitalist economies with an appreciation of (a) the variability exhibited in forms of ECONOMIC GROWTH over time and space and (b) the complex of social and institutional forces that serve to channel and sustain particular forms of economic growth, and defer crises, over periods of decades. Here, ‘regulation’ does not simply denote laws and rules but, after the French régulation, refers to processes of social regularization.

The central concept in regulation theory is the REGIME OF ACCUMULATION, a historically distinctive and relatively durable form of growth, based on a particular nexus of production/consumption and a supporting ‘mode of regulation’ (an ensemble of organizational forms, networks, and institutions, rules, norms and patterns of conduct, including a distinctively capitalist STATE). Regulation theory rose to prominence in the 1980s, following the French regulationists’ seminal analysis of FORDISM – the regime of mass production and mass consumption that prevailed in North America and Western Europe during the period between the mid-1940s and the mid-1970s. Fordism was accompanied by a ‘Keynesian-welfarist’ mode of regulation (including an interventionist NATION-STATE, a coordinated industrial relations system, a managed regime of international TRADE and finance, expansionist social welfare policies and the generalization of mass-consumption norms). Initially developed by Michel Aglietta, these arguments became well known in geography through the work of Alain Lipietz, Robert Boyer and their pre-eminent British ‘translator’, Bob Jessop.

Regulationist approaches became influential in GEOGRAPHY after the late 1980s, where they were invoked in debates around the decline and restructuring of Fordist manufacturing industries (paradigmatically, automobile production) and – more controversially – in the rise of putative successors to Fordism, such as flexible specialization, FLEXIBLE ACCUMULATION and POST-FORDISM (see Scott, 1988a; Tickell and Peck, 1992). For the most part, regulationists prefer to remain somewhat agnostic on the question of Fordism’s successor, despite the evidence of extensive experimentation in flexible production systems and new forms of governance, since the criteria for regimes of accumulation emphasize the medium-term reproduction and interpenetration of these structures, most often demonstrated through historical analysis.

Subsequent regulationist-inspired work in geography has focused on emergent forms of institutional regulation and GOVERNANCE, which are evidently less centred on the national state than had been the case in the Fordist era (see MacLeod, 2001), in contrast with the rather more economistic tradition of the original French school (see Boyer and Saillard, 2002). In turn, regulationist concerns have shaped the growing body of work on NEO-LIBERALISM, raising questions about the character, origins and socio-economic implications of such MARKET-oriented modes of regulation. While strict adherence to regulationist principles has become increasingly
rare in ECONOMIC GEOGRAPHY, the approach can be credited with helping to establish the widely held view that economies are socially embedded and institutionally regulated, rather than being guided by some ‘hidden hand’ of market forces.

**Relational database** Relational databases allow tables to be joined using columns of data common to the tables in which the various data sets are stored. For example, if one table has a list of countries and population size, and a second the countries and their land areas, then relating one to another by each country’s name permits calculation of population density. In GIS, the VECTOR data model is relational, storing the attributes and geography of objects in linked tables: for example, place named A [in table 1] has a boundary I [in table 2] that includes point 1 [in table 3] which has location \((x, y)\) [in table 4].

**Relativism** Understanding the production and justification of KNOWLEDGE as relative to the standards of the SOCIETY and CULTURE within which it arises. In emphasizing the social rather than individual variability of ideas and beliefs, relativism gives explanatory power to historical and geographical CONTEXTUALITY, and suggests that because knowledge is dependent upon context, truth will itself be relative. Relativism is opposed by UNIVERSALISM, which holds that true knowledge transcends context, and that reason can cut across contextual difference to judge the truth of knowledge.

HUMAN GEOGRAPHY has been concerned with both cultural and epistemological relativism. While explicit geographical arguments for relativism are rare, the term has a positive and negative presence in debate; as an approach consonant with long-standing geographical interests in cultural difference, and as an accusation levelled at those thought to be subverting the foundations of geographical enquiry. Cultural relativism is evident in anthropological enquiry concerned to understand the beliefs and practices of different societies without reducing them to some common explanatory schema. Fierce debate has proceeded over the moral and political consequences of cultural relativism. Geertz (1984) argues for ‘anti anti-relativism’, criticizing the argument that challenging universal standards of cultural understanding and judgement leaves one unable to provide moral or political commentary on the world. Geertz understands the debate as an expression of anxieties, ‘rather more an exchange of warnings than an analytical debate. We are being offered a choice of worries’ (Geertz, 1984, p. 265). Questions of cultural relativism connect to CULTURAL GEOGRAPHY, but also to EPistemological questions concerning reason, rationalism, science and HERMENEUTICS (Hollis and Lukes, 1982; Bernstein, 1983), often raised under the heading of POSTMODERNISM. Relativism serves as a marker in the psychology of THEORY. Relativist worry is countered by the PRAGMATISM of Richard Rorty (1979), who suggests that relativism is a problem only because of the FOUNDATIONALIST vocabulary through which orthodox PHILOSOPHY condemns it. With a different vocabulary, relativism disappears as a problem. Such an argument has been regarded as political and moral evasion by those from both the political Right and Left, who present themselves as defending traditional standards and/or maintaining positions for progressive political judgement. Debates over POSTMODERNISM in geography reflect such tensions and antagonisms.

Relativism has informed debates in the HISTORY OF GEOGRAPHY, and the geographies of SCIENCE. Relativistic understandings, from PARADIGM approaches through to SCIENCE STUDIES work, have presented science as a social practice: Livingstone (1992) discusses the consequences for the status of scientific and geographical knowledge. Smith (2000a) considers the implications for the geography of ETHICS and MORAL GEOGRAPHIES, showing that relativism is a moral and philosophical impulse with its own history and geography. Whether this relativistic understanding of relativism confirms or undermines relativism is another matter. For many in human geography, the means to address or side-step such questions has been provided by arguments for SITUATED KNOWLEDGE, seen as a means to negotiate the twin perils/demons/temptations of relativism and universalism. Clear resolution of such issues is unlikely: indeed, pragmatist and/or postmodernist arguments would suggest that searching for resolution is futile, and desiring resolution misguided.

Geertz (1984); Smith (2000a).
**relevance** Concern over the relevance of geography has been expressed since its foundation as a discipline; for example, in the promotion of geography as a practical science of empire. Consideration of how relevance has become a prominent word in geographical debate at specific times shows how ‘relevance’ can act as a marker for disciplinary disputes.

In the early 1970s, economic crisis, environmental resource debate and international conflict shaped debate on relevance, along with the sense that spatial science was becoming too abstract to gain purchase on public policy issues (Johnston and Sidaway, 2004, Ch. 9). At the 1974 Institute of British Geographers conference, IBG President J.T. Coppock, building on earlier applied geography, outlined geography’s possible relevance for governmental, planning and environmental agendas (Coppock, 1974). Among responses was David Harvey’s ‘What kind of geography for what kind of public policy?’, questioning how definitions of relevance had been shaped by political and economic circumstances: ‘The debate over relevance in geography was not really about relevance (whoever heard of irrelevant human activity?), but about whom our research was relevant to and how it was that research done in the name of science (which was supposed to be ideology-free) was having effects that appeared somewhat biased in favour of the status quo and in favour of the ruling class of the corporate state’ (Harvey, 1974b, p. 23). Exploring contradictions between policy demands and humanistic scholarship, Harvey sought a dialectical understanding of relevance: ‘The moral obligation of the geographer, qua geographer, is to confront the tension between the humanistic tradition and the pervasive needs of the corporate state directly, to raise our consciousness of the contradiction and thereby learn how to exploit the contradiction within the corporate state structure itself’ (p. 24).

Relevance re-emerged as a marker for debate in the late 1990s, prompted by concern over geography’s cultural turn, and worries that in a period of notionally social democratic government in the UK and the USA, geography was missing a policy opportunity. A 1999 issue of the Scottish Geographical Journal addressed relevance in terms of recent theoretical debates (Scottish Geographical Journal, 1999), Michael Dear discussing postmodernism and relevance as pertinence, political commitment, and policy application, while Susan Hanson posed relevance as a feminist geographical concept, working within and across different scales (see feminist geographies). Martin (2001b), however, argued that particular uses of such theory were producing an increasingly irrelevant geography. With an element of envy at economists’ apparent policy influence, Martin suggested that much contemporary economic and social geography had little policy or social relevance, due in part to the cultural turn. Martin presents a particular sense of relevance, and a particular characterization, even caricature, of ‘irrelevant’ and theoretically indulgent cultural enquiry. The terms of debate are further explored by Staeheli and Mitchell (2005), who address ‘the politics of relevance’ and ‘the social practices that condition relevance’ (p. 357) through interviews with public space researchers and analysis of Association of American Geographers publications. The publication of Staeheli and Mitchell’s article in the AAG’s *Annals* underlines how relevance debates have proceeded through institutions representing the discipline.

Those wary of instrumentalism in geography may in turn be wary of calls for relevance: pertinence may pass, commitments may wane and the relevant may become the untopical. It is important to appreciate and critique debates on relevance according to the temporality of their arguments, and to consider how geographical work not seeking immediate impact may nevertheless achieve different kinds of political and cultural influence.

**religion** Geographers approach the study of religion in a number of ways, from examining spatial patterns arising from religious influences, to the diffusion of religious beliefs and organizations, the relationship between religion and population, the impact of religion on landscape and landscape on religion, religious ecology, and the politics and poetics of religious landscapes, community and identity (Kong, 1990, 2001a).

The relationship between religion and geography may be traced to early Greek geographers, in their concern with cosmological models that reflected a world view shaped by religion (see cosmology). In the sixteenth and seventeenth centuries, the main preoccupation was ‘ecclesiastical geography’, the mapping of the spatial advance of Christianity in the world, propelled by the desire to disseminate
the Christian faith. ‘Biblical geography’ also developed during this time, involving attempts to identify places in the Bible and to determine their locations. In the late seventeenth century, and particularly in the eighteenth and nineteenth centuries, nature was seen as a divinely created order for the well-being of all life. Scholars adopting the physico-theological stance ardently defended the idea that in living nature and on all the Earth, there existed evidence of God’s wisdom. In the eighteenth and nineteenth centuries, following the lead of Montesquieu and Voltaire, the influence of the environment on religion was studied. Geographers adopted a highly deterministic approach when they sought to explain the essential nature of various religions in terms of their environments (see ENVIRONMENTAL DETERMINISM). This changed in the 1920s, when Max Weber’s writings marked a turning point by inverting the earlier environmentally deterministic doctrine to focus on religion’s influence on social and economic structures, and environmental and landscape change. Further, in the 1960s and 1970s, with environmental and CARRYING CAPACITY concerns, interest focused on the roots of environmental crisis, and a school of thought emerged that degradation was the result of the Christian belief that God gave humans dominion over the Earth.

Geographies of religion were sporadic for much of the twentieth century, and without major breakthroughs in perspective and approach, but especially from the 1990s onwards, the field has been reinvigorated. Kong (2001a) characterizes the emerging body of work as framed by an interest in the politics and poetics of SACRED SPACE, IDENTITY and COMMUNITY. Such research acknowledges that sacred space is contested space, just as the sacred is a contested category. Similarly, religious identity and community are subject to negotiations, embedded in relations of POWER, domination and RESISTANCE. Kong (2001a) urged geographers of religion to develop ‘new’ geographies of religion that emphasize different sites of religious practice beyond the ‘officially sacred’ (churches, temples, mosques, synagogues and the like); different sensuous sacred geographies; different religions in different historical and place-specific contexts; different geographical SCALES of analysis; different constitutions of population and their experience of and effect on religious place, identity and community; different DIALECTICS (socio-spatial, public–private, politics–poetics); and different moralities.

Since then, the terrorist attacks of 9/11 (see TERRORISM) have prompted new analytical attention to religion: most obviously to the rise of a distinctly radical or political Islam (Watts, 2007) – and here it is important to attend to the culturalist constructions of what Mamdami (2004) calls ‘Good Muslim, Bad Muslim’ – but also to the roles of Christianity, Hinduism and Zionism in shaping both provocations and responses to political VIOLENCE (e.g. Gregory, 2004b; Oza, 2007: see also JUST WAR). But this new interest in religion is not only political: the so-called ‘moral turn’ in geography, towards a renewed concern with ETHICS, has prompted Cloke (2002) and others to reflect on the place of the spiritual within HUMAN GEOGRAPHY, and Proctor (2006) and his collaborators to propose a new conversation between geographers on religion.

**REMOTE SENSING (RS)** Literally, the sensing (study) of an object using instruments of observation that are remote from (not touching) the object. This includes medical scanning but, more commonly, the object is the Earth, which aerial photography and satellite-based sensors are used to observe.

The basis of RS is that different types of vegetation, landform and land cover can have distinctive spectral signatures, meaning that they emit and reflect electromagnetic radiation in different ways. The truth of this is evident by observing that features of the LANDSCAPE have different colours and temperatures. However, RS involves more of the electromagnetic spectrum than our human senses allow access to, using infrared detection, thermal scanners, radar and microwaves, for example. RS can be passive, detecting natural radiation from an object; or active, targeting energy (such as laser pulses) on to the object, from the RS device.

RS has its origins with Gaspard-Félix Tournachon, a French photographer and balloonist who took aerial photographs of Paris in 1858. It was developed during the twentieth-century world wars and the COLD WAR (a flashpoint of which was when Gary Powers’ ‘spy plane’ was shot down over the Soviet Union, in 1960) and today is used for environmental analysis and monitoring as well as military SURVEILLANCE (see MILITARY GEOGRAPHY; WAR). In all cases, however, and despite the authority of techno-science invested in them,
RS data can be ambiguous, requiring careful interpretation.

One problem is that as RS signals pass through (for example) cloud cover and the atmosphere the signals are degraded. Second, although commercial satellites now offer very precise imagery (1–5 m resolution), if these are unavailable and if an object is smaller than the resolution offered by the sensor, then its spectral properties will be mixed with others around. Third, objects can be obscured by others above; for example, vegetation below a tree canopy.

In any case, human geographers may be less interested in land cover per se and more concerned with land use, or the social meaning given to places. A spectral signature is a co-production of nature and science; the way in which places are constructed and used is infused with social praxis and signification. There is no necessary one-to-one relationship between the science and social science.

However, an interesting development within RS has been to use methods of image classification that incorporate geographical thinking. Standard methods of classification generally are probability based (and Bayesian, notably the maximum likelihood approach: see Bayesian analysis). If it is known (from direct evidence) where various land cover types are located on some parts of the RS image, then it is possible to extrapolate and determine that the spectral signatures of other parts of the image more likely indicate one land cover type than any other. A more geographical approach is to classify pixels within the context of what is around them; to extract information about spatial configurations and associations that may say more about the land function than an aspatial analysis of land cover alone. Such techniques include space syntax (related to graph theory).

**Rent** Formally defined, rent is any payment to a factor of production over and above that necessary to keep it in its present use. While any factor of production can potentially accrue rent it is the analysis of only one factor—land—that dominates the discussion of rent within geography. This is partly because the payment for land is pure rent (a consequence of the fact that land costs nothing to produce, and not the case for other factors), and partly because land is bound to location, thus lending itself to geographical analysis.

Rent is the price of land, and because land is differentiated by both quality and location, each land plot will have a different rent level. Two quite different approaches have been deployed to explain differential land rents. The orthodox view of neo-classical economics treats land as any other commodity, with rents set by forces of supply and demand. Rent is determined as in a giant auction, with rational buyers and sellers of land meeting to haggle over price. Those plots of land with characteristics most demanded given the available supply will fetch the highest rents, and in the process determine land use. In contrast, Marxist economics emphasizes the power of different social classes in determining rent levels. While land characteristics play a role in setting rent, they are always subordinate to a set of wider social relations characterizing capitalism around the inequality of power and resource ownership. Without inclusion of this larger context, no analysis of rent is complete.

Both traditions have provided analyses of the role of land rent within explicitly geographical settings. The von Thünen model is the best known within the neo-classical tradition (Chisholm, 1979). Assuming that agricultural crops are cultivated at varying distances around a town, which is also the sole market, a competitive bidding process among farmers results in plots of land closer to the town centre receiving differentially higher rents than those farther away. In this case, the spatial pattern of land rents is explained by differential savings in transport costs that allow farmers closer to the town to bid higher rents than farmers farther out. Rents are thus set by the supply and demand for plots of land differentiated by location. The von Thünen model has also been extended to explain rents within the city. William Alonso’s bid-rent approach (see Alonso model) draws upon differential transportation costs of commuting along incomes to explain urban land rents and residential land-use patterns.

The Marxist approach to rent is most associated with writings by David Harvey (1999 [1982]) and Neil Smith (2008 [1984]). Harvey draws directly on Marx’s categories of absolute and monopoly rent to stress the role of class power in determining rent levels. Landowners use their clout either to restrict investment in the case of absolute rent, or to constrain the supply of land in the case of...
**representation** A complex concept not only because of the intricate disputes in art (the ‘discovery’ of perspective) and perception) intelligible and identifiable. Bringing together the achievements of Renaissance art (the ‘discovery’ of perspective) and Enlightenment language (scientific objectivity, classificatory order), this ‘naturalist’ or ‘realist’ theory of representation is characterized by the relationship between two assumed metaphysical constants: the artist/viewer (or universal, visual experience) on the one hand, and nature (or the objects of external reality) on the other. From this perspective, the history of representation is the study of constant mutations reflecting the increasing sophistication of artistic execution in relation to the changing appearances of the world. However, morphology and advancing technical expertise are not by themselves history: indeed, ‘history is the dimension [this understanding of representation] exactly negates’ (Bryson, 1983). Recognizing this, representation is analogous to what Edmund Husserl (1859–1938) calls the ‘natural attitude’, a perspective whose increasingly fidelity to a reality ‘out there’ is as much a scientific and aesthetic practice as it is an epistemological premise. ‘It is the aim of the sciences issuing from the natural attitude to attain a knowledge of the world more comprehensive, more reliable, and in every respect more perfect than that offered by the information received by experience’ (Husserl, in Heath, 1972). It is Husserl’s student, Martin Heidegger (1889–1976), however, who most decisively equates representation with science/knowledge and posits it as the foundation – and fateful flaw – of Western philosophy. Manifest in what Heidegger called the modern ‘age of the world picture’, the representational model depends on the construal of truth as ‘correspondence’ or ‘accordance’ (Heidegger, 1962 [1927]). Representation or ‘En-framing’ (Ge-stell) thus not only assumes that the world is purely present-at-hand (vorhanden), an object to be submitted to our pitiless and possessive gaze, but turns it into a ‘standing reserve’ for our technical domination and habitual instrumentalization. What such an attitude forgets, however, is that the ‘world is never [that] which stands before us and can be seen’ (Heidegger, 1962 [1927]). Rather, true experience for Heidegger is a matter of ‘uncovering’ the hidden, of revealing what might be concealed rather than accurately and anonymously representing what appears to be.

But if Heidegger’s indictment of representation suggests a phenomenological critique (see phenomenology), other analyses insist on the historical specificity of representation and its implication in the production of knowledge. For Michel Foucault (1926–84), representation not only has a history but a precise
RESISTANCE

moment of epistemic formation coincident with the onset of what he calls the Classical Age (1600–1800). Before the end of the sixteenth century, an age characterized by a theory of ‘resemblances’ or ‘similitudes’, Foucault argues, images and words were understood as decipherable hieroglyphs, as so many figural or iconic ‘signatures’ that bore intrinsic affinities to the things of a divinely ordained world. The result was an essential seamlessness, a ‘non-distinction between what is seen and what is read . . . the constitution of a single, unbroken surface in which observation and language intersect to infinity’ (Foucault, 1977). For reasons that Foucault unfortunately fails to explicate, the Classical Age emerges when this unity is shattered by a growing awareness of the binary nature of representation; that is, of the discriminatory judgement of identity and difference, of the placing of things in differential relation to each other as the means to describe and systematize the manifold objects of the external world. Knowledge now begins to occupy a new space. It is the space within representation itself, inside the tools of its language, classificatory systems, and modes of naming and viewing. Natural history and concomitant taxonomic or tabular orderings of the world owe their triumph precisely to representation so understood. Importantly, the only thing that is not, and cannot, be included within this representational frame is the act of representation itself. Indeed, it is only in the absence of the viewing, naming and describing subject, that representation can claim its authority as infallible knowledge.

With this analysis, and Foucault’s subsequent charting of the shift from a Classical to a Modern episteme, in which language becomes opaque as Man is arranged at the centre of knowledge, the stage is set for understanding representation as a discursive practice, as a kind of work (see DISCOURSE). Alternatively known as the social constructivist approach (see SOCIAL CONSTRUCTION), this perspective recognizes that while concepts and signs may have some material dimension (we do, after all, emit sounds when we speak, paint marks on a canvas, transmit electronic impulses when taking a digital photograph), the meaning of such things depends not on any pragmatic quality but on their symbolic and social function. It is for this reason that Ferdinand de Saussure (1966) preferred the word ‘signify’ rather than ‘represent’ for what words and concepts do: they do not describe a pre-existent reality, but constitute what counts and is valued as reality. Influenced by Saussarian linguistics and rehearsed within various registers of POST-STRUCTURALISM, the constructedness of representation is now a chief interpretive principle cutting across a wide sampling of contemporary theories, including those of human geography. Indeed, one can say that ‘geo-graphy’, in its etymological connection to ‘earth-writing’, holds the idea of ‘representation-as-text’ at its practical and theoretical root (Cosgrove and Daniels, 1988; Barnes and Duncan, 1992; Duncan and Ley, 1993; Gregory, 1994).

However, acknowledging the constructed nature of representation is one thing; investigating the inherent partiality and limitations in anything constructed is another. Alongside questions of who and what it is that ‘represents’ (i.e. what enunciative, rhetorical or institutional position is involved in the act of representing) attention also has to be paid to the restrictions of the representational model: to not only what it excludes, but also what it inhibits in accessing the perceptual practices of our sensory and somatic lives. In recent HUMAN GEOGRAPHY, the disappearance of the textual dimension in so-called ‘NON-REPRESENTATIONAL THEORY’ offers one such address. Concerned to close the distance between subject and object – the very distance implied by representation as mediation, illustration or derivative sign-language – non-representational theory attends to how certain SPACES, experiences and states act directly on the BODY, addressing the manifold AFFECTS, sensations and, indeed, visibilities of the world in the subject’s felt engagement with it. Here the re of representation, or the substitutive value that this re indicates, makes way for a certain intensification of presentation, for an immediacy of presence of which any secondary reproduction of the world can give no account (Dewsbury, Wylie, Harrison and Rose, 2002).

resistance In HUMAN GEOGRAPHY, resistance has two distinctive meanings: political resistance, the more common usage, refers to resistance to domination or oppression; psychic resistance refers to unconscious attempts to maintain repressions of traumatic or dangerous memories (see PSYCHOANALYTIC THEORY). Pile and Keith (1997) discuss how the two concepts work in relation to each other.
Debates about political resistance crystallize key trends in CRITICAL HUMAN GEOGRAPHY. MARXIST GEOGRAPHY has a long tradition of studying collective organizing and everyday resistance to CLASS exploitation; and struggle against PATRIARCHY is well articulated in FEMINIST GEOGRAPHIES. The geographical embeddedness of political and cultural action has been explored in work on SOCIAL MOVEMENTS, highlighting: how particularities of PLACE influence the emergence, character and strategy of movements (Routledge, 1993); what geographical dilemmas labour unions face in the age of global capital (Herod, 1998: and see LABOUR GEOGRAPHY); and the importance of social movements in shaping political and social geographies (Miller, 2000).

An interest in CULTURAL POLITICS and the pursuit of the CULTURAL TURN led to two developments in the geographical study of resistance. First, the interpretative frame was enlarged to include myriad everyday symbolic and material practices, which contested not only class exploitation but also gender, racial, sexual (and other) forms of domination and oppression. James Scott’s Weapons of the weak (1985) was a key text, in which he identified foot dragging, desertion, false compliance, pilfering, feigned ignorance, arson, sabotage and more as ‘everyday resistance’. These practices required little or no coordination or planning, made use of implicit understandings and informal networks, and typically avoided any direct or symbolic confrontation with authority (1985, p. xvi). However, when almost every action is conceptualized as resistance, critical distinctions between effective and ineffective political resistance, and commitments to collective organizing and the coordination across different forms of domination, may be lost (Pile and Keith, 1997).

Second, resistant subjects were understood as authoring their political IDENTITIES in relation to multiple axes of POWER, and dominant structures, discourses and actors within society (Castells, 1997). Identity formation is thus complex in terms of both the multiplicities of identities negotiated by each individual and the HYBRIDITY of resultant resistance practices (see THIRD SPACE; Pile and Keith, 1997). Concerns with the latter have been influenced by Foucault’s (1990 [1976]) version of POST-STRUCTURALISM, which views power as insinuated throughout all social activity, inherent in practically all social and political relationships. The operations of power, domination and resistance are seen as integrally rolled up in articulations of society and SPACE, resulting in the entanglement of resisting and dominating practices; for example, through the creation of internal hierarchies, the silencing of dissent, or how various forces of HEGEMONY are internalized and reproduced within resistance practices (Sharp et al., 2000).

With the intensity of the processes of NEO-LIBERAL GLOBALIZATION, concerns over the ways in which the production of SCALE is itself an outcome of political struggle (Smith, 1993) are now turning to networked forms of politics and resistance (Grewal and Kaplan, 1994; Featherstone, 2003, 2005b; Routledge 2003; Massey, 2004). This challenges the way in which resistance has been previously theorized through bounded versions of space and PLACE, and is crucial for engaging with the dynamic transnational networks of opposition to globalization (see ANTI-GLOBALIZATION; TRANSNATIONALISM).

**resort life-cycle model** Originally developed by Butler (1980) (see figure), the tourist resort life-cycle MODEL depicts an almost inevitable pattern of development in five phases. First, there is a phase of exploration characterized by small numbers of relatively wealthy tourists ‘finding’ the destination. Second, local capital and populations become involved in developing the resort. Third, there is development as AGGLOMERATION effects lead to increasing returns. Thus as visitor and business numbers increase, the knowledge and skill base expands. More visitors mean more capital, which means more investment in facilities and accessibility, which makes the destination more attractive, and so on. This develops into a fourth phase of consolidation, where competition among increasing numbers of providers to gain large volumes of tourists...
entails cheap products, which in turn have low margins and thus reduce further investment. The effects of expansion may also destroy the very qualities that once made the place appealing. The resort may exceed its ecological or social ‘carrying capacity’, leading to a fifth phase of stagnation.

Butler (1980); Smith (1992c).

**resource** A deceptively peaceable term that conceals the profoundly political relations through which humans attribute value to the non-human world. ‘Resource’ is one of the core categories of modernity: like ‘nature’ and ‘culture’, its origins lie in the revolution of socio-natural relations associated with the emergence of capitalism. The distinctions and differentiations enabled by the category of ‘resources’ – between productive, valued assets and unproductive ‘wastes,’ for example – are closely bound to notions of development and state formation, and play a key role in the organization of contemporary society. The ‘productivist’ associations that adhere to the term give it wide application beyond environmental phenomena: technology, skills and employees, for example, are frequently described as resources. These applications illustrate how the term captures a fundamentally social relationship: the attribution of (economic) value by a dominant group to attributes and capacities that provide functional utility for that group.

Traditionally, a ‘resource’ describes a product of biological, ecological or geological processes (game, soils, mineral ores, timber, water) that satisfies human wants (see natural resources). The utility of these environmental goods and their contribution to human welfare may be experienced directly – for example, as material inputs such as food and shelter that enable subsistence – or indirectly via its role in exchange. In addition to these classic productive inputs, the category of resources also includes a range of ecosystem services, such as carbon sequestration, flood attenuation and the maintenance of biodiversity, that are now recognized as critical to the functioning of the Earth’s life-support systems (Costanza et al., 1997). Many of these provide important ‘sink’ functions by assimilating wastes produced during the use of environmental goods. There is also a range of non-extractive and non-utilitarian ways in which physical environments can be considered to provide ‘resources’: recreational amenity, aesthetic appreciation, moral worth and spiritual inspiration imply the attribution to the natural world of a complex range of value systems (see resource management).

Work on resources engages with questions of value, knowledge, scarcity and sustainability that are at the heart of modern environmental geography. Three distinctively geographical understandings of the nature and function of resources have emerged.

(1) **Resources: neither natural nor cultural.** At the core of geographical work on resources is the recognition that resources are ‘cultural appraisals’ of the non-human world. This idea, which can be traced in the writings of nineteenth-century political economists such as Ricardo and Mill, is articulated most clearly by Zimmerman’s (1933) aphorism that ‘resources are not; they become’. In his World resources and industries, Zimmerman argues against the vernacular view of resources as ‘material fixities of physical nature’ and proposes that ‘neutral stuff’ acquires the status of a resource once it is recognized as having some functional value. Work by geographers has explicitly broadened the category of resources away from a restricted focus on physical stocks and flows, situating resources as an interface or boundary zone between societies and the vast range of different materials that biological, geological and atmospheric systems produce. Burton, Kates and White (1993) systematized this view of resources as an interface between human and physical systems, noting the symmetry between positive and negative social appraisals of the environment (‘resources’ versus ‘hazards’). Recent work on life sciences and biotechnology questions altogether the categories ‘human’ and ‘physical’, and highlights the need for non-dualistic modes of thought within geography. To varying degrees, then, geographers have insisted that resources are hybrid forms, ‘socio-natures’ that are neither purely natural nor purely social (Swyngedouw, 1999). By defying categorization as either nature or culture, resources highlight the insufficiency (and instability) of many of the analytical categories on
which modern geography is founded (see HYBRIDITY).

(2) **Resources as relational.** Recent work by geographers starts from the premise that resources can be more productively analysed as a set of social relations between (often distant) groups rather than as discrete ‘things’. This so-called ‘relational approach’ works against the reification of resources by turning the analytical lens back on to society: What is it about the needs and wants of a society, and the way a society is organized, that transforms a component of the non-human world into a resource in a particular time and place? (See also COMMODITY.) At its most general, a relational approach de-naturalizes resources: it draws attention to how what counts as a resource is at least as much a matter of social, political and economic conditions as it is any intrinsic or inherent properties. More specifically, relational thinking about resources can provide a potent critique of popular assumptions that scarcity is an external physical condition setting the bounds of human possibility (Harvey, 1974a). In the face of neo-Malthusian claims about food, energy and other material shortages (see MALTHUSIAN MODEL), thinking about the social relations that define a resource highlights how access and availability are mediated by wealth and power: simply put, the rich and powerful do not starve. This insistence on the limits to resource availability being largely (although not exclusively) internal to the economy can be politically empowering, as it suggests how apparent shortages might be resolved not by increasing supply, but by changing the way in which resources are allocated within society, the uses to which they are put, and cultural expectations about the costs of use.

(3) **Resources: fighting words.** Resources have long been recognized as objects of geopolitical struggle and intrigue: control of water and oil, for example, are frequently tipped to be the battlegrounds of the twenty-first century (Klare, 2002: see CONFLICT COMMODITIES; RESOURCE WARS). However, many of the most intractable contemporary political tensions surrounding resources are not struggles over a stable category, and it is the very definition of lands as resources that is at stake. Thus recent work considers the cultural, economic and political processes by which parts of the non-human world are ‘coaxed and coerced’ from settings where they already may be valued in quite different ways (Tsing, 2004). While chimpanzees (LABORATORY experimentation), exposed uplands (wind power sites) and tropical agro-diversity (genetic diversity) are strikingly heterogeneous, what they share in common is that their status as resources (noted in parentheses) is achieved only in the face of opposition and resistance. The apparent objectivity and universality of the ‘resource imaginary’ disguises its particularity and the silencing of alternative conceptualizations of the non-human world. For example, to describe bauxite as a resource overlooks the pre-existing land uses and land ownership that must be undone to establish mines and realize the exchange value of the ore (Howitt, 2001b). It is for this reason that a number of authors refer to the ‘violence’ of the resource imaginary, thereby placing resources at the centre of human geography’s encounter with POST-COLONIALISM (Braun, 1997; Peluso and Watts, 2001).

**resource economics** A practical art and field of study that understands NATURAL RESOURCES as a particular class of the ‘scarce goods’ described by NEO-CLASSICAL ECONOMICS, and that seeks to understand the opportunities and limitations of using MARKETS as the primary social mechanism for making collective decisions about their production, allocation and CONSUMPTION. Although recognizing that resource availability is finite in an absolute physical sense, a core axiom of resource economics is that any meaningful measure of a RESOURCE’s availability must understand its relation to CAPITAL, labour and socio-technical knowledge – relations that can be expressed by reference to price (Barnett and Morse, 1963). A normative goal of resource economics is to improve utility maximization by attributing prices to environmental goods and services.

**Suggested reading**
Tietenberg (2005).
**Resource Evaluation** A component of the Resource Management cycle involving physical, economic and/or cultural appraisal of natural resources. Evaluation generates knowledge about a resource that is used to shape future strategies towards its use, conservation or management: it may, for example, provide a ‘baseline’ against which to judge the effects of human intervention; it may calculate potential commercial values of a resource for a range of possible uses; or it may be used to review the consequences and effectiveness of management strategies. Although often employed as a top-down administrative tool, participatory use of the techniques of resource evaluation can challenge ‘expert’ assumptions about the value, function and condition of a resource.

**Resource Management** The knowledges and practices associated with monitoring, evaluating, decision-making and intervention in environments, with the objective of ensuring that these environments produce goods and services of value to society. Resource management activities are undertaken by a wide range of actors and institutions, including private-sector organizations, national and local governments, communities, households, peasant studies and political ecology. Highlight agriculture as the ‘original’ resource management activity: the farmer is a land manager who makes (highly constrained) decisions about inputs to and outputs from a plot of land.

Etymologically, ‘management’ conjoins two distinctive roles: the trainer or director (manager), and the careful housekeeper (ménager) (Williams, 1983 [1976]). Resource management is the ‘applied science of possibilities’ (Hays, 1959): the task of the resource manager is to ensure the orderly production of environmental goods and services over time and space. The codification of this role – and the elevation of resource management as a specialized branch of knowledge – first appeared on large European landholdings: von Thünen’s work on land rent in *The isolated state* (1966 [1826]), for example, developed from a concern to determine optimal patterns of agricultural land use on his Prussian estate (see von Thünen Model). Resource management science also developed as part of the colonial project, as Europeans wrestled with unfamiliar tropical ecologies and sought ways to attain their control and maximize the yields of commercially valuable crops (Scott, 1998b). The emergence of resource management as a distinctive social task marks a historical disjuncture: it is the point at which scarcity and abundance are recognized to be the product of social organization, and society begins the active production (‘husbandry’ or ‘stewardship’) of environmental goods and services that formerly had been taken as ‘free’ inputs.

Recent efforts to develop planetary management regimes for global resources – biodiversity, global climate and the oceans – are an explicit recognition of this ‘underproduction of the environment’ and replicate a process that occurred earlier at the national scale for many productive resources such as timber, soils, water and game (e.g. the Conservation Movement of the early twentieth century in the USA).

Within geography, resource management has been viewed as a promising vehicle for achieving the integration of human and physical geography (Johnston, 1983). Although geography programmes often contribute to the teaching of conservation and resource/environmental management, much recent human geography is critical of the knowledge-claims and ‘utilitarian, reductionist, technocentric and market driven’ practices of conventional resource management (Howitt, 2001b). Encounters between resource managers and indigenous peoples highlight the particularity and ethnocentrism of the instrumentalist ‘resource imaginary’, and the way in which conventional resource management works to empower those who share its epistemology, while disenfranchising (and often disposessing) those who do not. Yet there are a stunning array of other rationalities – aesthetic, spiritual, communitarian – and indigenous environmental knowledges that may provide alternative criteria and values for management. Recent work seeks to bridge the gap between expert and indigenous knowledges via processes such as stakeholder consultation, the development of multi-actor management systems (that combine the interests of private, public and other interested parties) and community-based natural resource management. (See also natural resources.)

**Suggested reading** Bakker and Bridge (2006); Howitt (2001b).

**Resource Wars** Conflicts over the control of natural resources are frequently simply called resource wars. Through much of the twentieth century, supplies of resources to feed and fuel industrial states were a matter of concern to war planners in many imperial states. During the Cold War, American
concerns over supplies of minerals and oil were part of its military planning. A large literature has documented the relationship between fights to control resources and geopolitics, although it has also pointed out that simple conflicts over resources are less frequently a direct cause of warfare than simplistic Malthusian assumptions of scarcity leading to conflict usually suggest (Le Billon, 2004: cf. MALTHUSIAN MODEL). The recent growth of the global economy and the ability to substitute and invent new materials in industrial processes has substantially reduced the concern with potential wars over many resources on the large scale. However oil may yet turn out to be the ‘resource war’ exception that proves this rule.

Research in the 1990s gradually connected resources with contemporary violence in many states in the global south. It became clear that in many places in the developing world where there were large supplies of natural resources, there was also a prevalence of violence, corruption and in some cases outright warfare (Le Billon, 2005). Research has now documented how this ‘resource curse’ distorts development by making the political elites who control the resource rents hugely wealthy, and in the process frequently stifles national economic innovation. It also makes clear that there are large incentives to fight to control the rent from resource extraction, which, in the absence of a strong state and available economic alternatives, frequently fuels civil wars (Bannon and Collier, 2003).

At the largest scale, these matters are now of concern in the discussion of global oil supplies and the sometimes severely distorted political structures of oil-exporting states, in particular in the middle east. This now directly connects resource curse arguments with the traditional geopolitical themes of ensuring supplies for distant markets. In particular after the Iranian revolution, and during the subsequent war between Iraq and Iran in the 1980s, American military power became increasingly involved in the Gulf to control the flow of oil. This has grown dramatically as a consequence of invasion of Iraq in 2003, where the US policy in the region is now directly tied to enforcing the flow of oil, with all the potential this has for further violent conflict (Klare, 2004).

**Restructuring** Change(s) in and/or between the constituent parts of a circuit of social reproduction, emanating from the dynamics of the circuit itself or from contradictions and crises within it.

Such changes may represent a response to changed conditions induced, for example, by time–space compression, technical change, or conflicts between labour and capital in the workplace, or transmitted through the competitive conditions endemic to capitalism. The inherently competitive social relations of capitalism generate a permanent tendency to transformation or restructuring, but the term has come to be more widely used since the end of the long boom in the late 1960s and early 1970s (see crisis; modernity). For some, it is a process closely associated with the transition from one kondratieff cycle to another or from one regime of accumulation to another or with the speed of the circulation of capital and the increasing globalization of the world economic geography.

As such, restructuring may be thought to be synonymous with development (Streeter, 1987), or at least with certain forms of development. But it goes beyond that. Thus Laurence Harris (1988, p. 10) points out that although there is ‘no easy, obvious way to distinguish structural from other changes in the abstract . . . some periods seem to see greater and more significant shifts than others’. He identifies four such periods in the UK since the early nineteenth century: the 1830s and 1840s; the 1880s and 1890s; the 1930s and 1940s; and the 1970s and 1980s. But what marks these out as periods of restructuring? Apart from certain specific and system-wide components of changes (e.g. those identified by Harris, 1988, pp. 11–14), restructuring involves not just quantitative change but pronounced qualitative transformations of the ways in which consumption, production and exchange take place and relate to each other. Furthermore, as a set of essentially qualitative changes operating on the circuit of social reproduction, restructuring necessarily involves transformations of the conditions in which such circuits create and find their conditions of existence.

At an extreme of structural change, such as occurred in the transformation of the former state socialist societies during the late 1980s (see post-socialism), the social relations through which the dynamic, direction and mode of evaluation of social reproduction are shaped are themselves transformed and the circuit of social reproduction comes to operate on completely different principles, often associated with profound economic disruption and
profound social pathologies. The parallels between perestroika in the former Soviet Union and capitalist restructuring are marked:

*Perestroika* is inevitable when existing economic conditions do not respond to ... the needs of development of society and the demands of the future. Here it is necessary to change the economic system, to transform and renew it fundamentally. For this transformation restructuring is necessary not just of individual aspects and elements, but of the whole economic system. (Anganbegyan, 1988, p. 6)

This strategy for development – fatefully for Soviet socialism – presumed uskorenie, an acceleration of economic growth, and glasnost, or openness, to be achieved by the spread of democracy and local self-management.

The more insidious, continuous and widespread social and political consequences of restructuring driven by the imposition of capitalist social relations and the norms, directions and criteria of evaluation that go with them within the third world are dramatically illustrated in Michael Watts’ (1992) harrowing account of ‘fast capitalism’ and the exploitation of oil in Nigeria.

Less dramatic but still profound changes may occur within the dynamics of particular forms of social reproduction, such as capitalism (e.g. Harris, 1988). Manuel Castells (1989, pp. 21–8) suggests that certain transformations of the capitalist mode of production on a global scale during the twentieth century are structural in form. Certainly, they serve to exemplify the point that restructuring is qualitative as well as merely quantitative. The Great Depression of the late 1920s and early 1930s and the associated disruption of the Second World War ‘triggered a restructuring process that led to a new form of capitalism very different from the laissez-faire model of the pre-Depression era’ (p. 21). The new model relied on restructured relations between capital and labour whereby stability in capitalist production was exchanged by the recognition of union rights, rising wages and the development of welfare states; Keynesian regulation and intervention in circuits of capital articulated primarily at the national scale; and the creation of a new set of international regulatory institutions around the international monetary fund, underwritten by the power of the economy of the USA.

The limits of this model – manifest, for example, in rampant inflation, increases in returns to labour and fiscal crises of the state – were formative influences (for an attempt to assess the articulation of these formative processes, see Yergin and Stanislaw, 1998) on the creation and imposition of a restructured model of the circuit of capital involving the appropriation of an increased share of the surplus by capital based around increases in productivity, changes in the labour process and restructuring of labour markets in terms of: deregulation and reductions in the power of trades unions; a shift in the role of states from intervention to facilitation of capital accumulation; and further deregulation and opening up of local and national spaces to global competitive processes – not least through the increasing significance of globally sensitive and active spheres of reproduction (see Economic Geography), acting through global financial centres.

Restructuring may involve one or more of a number of transformations:

- Structural adjustment, which Streeten (1987, p. 1469) defines as ‘adaptation to sudden or large, often unexpected changes’ to an economic geography. Such changes may, however, be forced by powerful institutions such as the World Bank in, for example, making aid dependent on profound changes in macro-economic policy. Structural adjustment programmes have been designed to open up underdeveloped economies to the global economic geography in order to maximize their potential for development. In this sense, they may be viewed as a means through which the social relations of capitalism may be spread through the underdeveloped world in ways that make them secure for the future by insisting, for example on:
  - transformations in the modes of coordination and exchange within circuits of social reproduction (by, for example, opening up economies to the pressures of market forces and international competition) with the objective of removing local rigidities and reducing vulnerability to shock through means such as increasing the flexibility of markets, the provision of productive infrastructure and the development institutions oriented to export markets;
  - switches of capital between forms of investment (direct/indirect), sphere of circulation of capital (reproduction/production/realization) and sector (e.g. deindustrialization);
  - geographical switches of capital (here/there – see New International Division
OF LABOUR). Such changes clearly have substantial implications for the UNEVEN DEVELOPMENT of places (re/dis)incorporated from circuits of capital (see Allen and Massey, 1988; Allen, Massey, Cochrane et al., 1998).

More narrowly, the restructuring of production (e.g. Graham, Gibson, Horvath and Shakow, 1988) may have significant consequences well beyond production itself:

- changes in the process of production as a consequence of ECONOMIES OF SCALE, the concentration of centralized capital (see MARXIST ECONOMICS) or transitions from one REGIME OF ACCUMULATION to another (see REGULATION SCHOOL);
- changes in the organization of production along the production chain (see Dicken, 1998, Ch. 1);
- changes in corporate organization – such as those associated with forms of INTEGRATION within production, multidivisional organization and decentralization in the attempt to combine corporate size whilst maximizing entrepreneurial initiative within the organization;
- the development of tasking flexibility in production based, for example, upon ECONOMIES OF SCOPE or temporal flexibility based, for example, on JUST-IN-TIME forms of supply along the production chain;
- a redefinition of a firm’s core activities, so redefining its sphere of activities, with profound implications for the size and status of its labour force;
- a repositioning of the firm along the production chain to deal with downstream service functions;
- a geographical reconfiguration to redefine the role and functioning of individual productive units; and
- an organizational restructuring involving a redefinition of the firm’s internal and external boundaries.

The restructuring of production in these ways has implications for, or may be undertaken through, changes in the labour process or the DIVISION OF LABOUR, but it relates to wider processes of change within which labour is necessarily caught up, and over which it has less direct influence than changes in the immediate conditions of work.

Although restructuring is a term applied mainly to economic transformation, and is frequently driven by and is obviously manifest in the activities of individual firms and capitals, it cannot be restricted to the economic sphere. It involves, and so is predicated upon, responsiveness elsewhere in SOCIETY. Nor is restructuring reducible merely to economic dynamics. It frequently requires the support and or restructuring of the STATE or, as in the case of perestroika or the market-based restructuring around the discourses of monetarism in the USA (‘Reaganomics’) and, to a more dramatic extent, the UK (‘Thatcherism’) or New Zealand (‘Rogernomics’) cases, is driven by the transformation of regulatory practices instituted by the state and so generates a range of IDEOLOGICAL and political relationships and struggles (see, e.g., Walker, 1997).

retailing The marketing and distribution of COMMODITIES to the public. Retail geography is conventionally defined as the study of the interrelations existing between the spatial patterns of retail location and organization on the one hand, and the geography of retail consumer behaviour on the other. Retail geography is often situated at the overlap of related sub-fields, including ECONOMIC GEOGRAPHY, the geography of SERVICES and URBAN GEOGRAPHY.

Work within retail geography appears to follow one of two broad trajectories. The historically dominant perspective is somewhat more applied, and neo-classical (see NEO-CLASSICAL ECONOMICS; cf. special issue of GeoJournal, 45 (4) (1998)). Since the late 1980s, a self-defined ‘new’ retail geography has emerged, in clear opposition to the former. Initially influenced by POLITICAL ECONOMY perspectives, this has subsequently become responsive to developing debates within CULTURAL GEOGRAPHY (for an overview, see Wrigley and Lowe, 2002).

Mainstream retail geography has certain general characteristics. Broadly speaking, neo-classical economic principles predominate, with considerable emphasis placed upon the structuring role of individual consumer decisions. This can be seen in the continuing influence of CENTRAL PLACE THEORY (cf. Parr, 1995), the refinement of which played an important role in the QUANTITATIVE REVOLUTION of the 1960s. With strong links to marketing (Jones and Simmons, 1993), retail geography is also applied in its emphases. Retail geography has
conventionally adopted a specific spatial focus, with enquiry usually directed at the intra-urban and, occasionally, at the regional scale. The geographies of consumer behaviour and retail organization are also frequently theorized as some function of distance (distance decay), actual or perceived.

This perspective has come under challenge, as political economic and cultural perspectives have been brought to bear on retail geography. Initial insights were drawn from the allied field of industrial geography, which saw the import of Marxist perspectives into spatial–economic analysis in the 1980s. One analysis, by Ducatel and Blomley (1990), drawing from Marxist insights into economic structure, sought to re-theorize retail capital both as a vital component of a larger capitalist system, and as characterized by its own internal logic (see marxist geography). Although this re-theorization has been criticized (Fine and Leopold, 1993), the call for a political economic perspective on retail capital generated a response, particularly in the UK. The ‘new economic geographies of retailing’, as Wrigley and Lowe (1996) styled them, paid particular attention to the phenomenon of retail restructuring. More recently, geographers have explored commodity chains and power relations between retailers and suppliers (Hughes, 2005).

Over the past decade or so, the ‘new retail geography’ has become more attentive to the cultural geographies of retailing. In line with a more generalized recognition that economic processes are culturally coded (see cultural economy), retail geographers have again become interested in questions of consumption. However, consumption is not seen simply as the unproblematic expression of consumer demands, but is understood as a critical site for the expression, reproduction and contestation of various identities (see identity). One question, in this regard, is the way in which gender roles are formed in retail spaces. Certain retail sites – notably the department store and the mall – have received particular attention (Blomley, 1996). However, it is interesting to see other retail spaces coming under scrutiny, including the car-boot sale (Crewe and Gregson, 1998). Excellent reviews of and commentaries on this literature are provided by Crewe (2000, 2001, 2003).

Retrodution

A mode of inference (particularly associated with realism) in which events are explained by postulating (and then identifying) the mechanisms by which they are produced. Those mechanisms realize causal powers, the potential causes of events that have to be activated (as with the striking of a match and the creation of fire): those powers may not be observable (as with gravity) and their existence has to be retroduted from appreciation of observed events.

retrogressive approach

A method of working towards an understanding of the past by an examination of the present (cf. RETROGRESSIVE APPROACH). The term achieved wide circulation through the work of Mac Bloch (see annales school), who insisted that the analysis of past landscapes required the prior analysis of the present landscape, ‘for it alone furnished those comprehensive vistas without which it was impossible to begin’. Likening history to a film, Bloch argued that ‘only the last picture remains quite clear’, so that ‘in order to reconstruct the faded features of others’ it is first necessary ‘to unwind the spool in the opposite direction from that in which the pictures were taken’ (see Friedman, 1996).

retrospective approach

A method, principally employed in historical geography, the focus of which is understanding the present, and which considers the past only insofar as it furthers an understanding of the present (cf. RETROGRESSIVE APPROACH). The retrospective approach, much advocated by Roger Dion (1949) in his study of French agrarian landscapes and similar to the historic-evolutionary approach in classical German cultural geography, considers that an understanding of the present landscape poses problems of explanation that can only be solved by a retrospective search for their origins.

The study of the past for the light it throws on the present (cf. RETROGRESSIVE APPROACH). The approach would make historical geography a prerequisite for contemporary analysis. Its most explicit advocate was Roger Dion (see annales school), who believed that a consideration of the present landscape poses problems that can only be solved by a search for their origins; but the approach can evidently be extended beyond the analysis of the landscape and has much in common with ‘genetic’ or ‘historical’ explanations more generally.

revealed preference analysis Statistical methods, many based on MULTI-DIMENSIONAL SCALING, for deriving an aggregate set of decision-rules from a series of individual decisions, as in the choice of shopping centres by consumers. The individual choices are termed examples of behaviour in space and are particular to a given configuration (the distribution of shopping centres in one town, for example). The general rules, unconstrained by any particular arrangement, are the revealed rules of spatial behaviour (Rushton, 1969). Studies of other behaviours – such as voting – use similar approaches. (See also BEHAVIOURAL GEOGRAPHY.)

rhetoric The term is classically defined as the art of persuasion and eloquence. The history of Western thought could be understood as a long quarrel between serious reason and rhetoric. From one perspective, ENLIGHTENMENT, rationality and SCIENCE overcome religion, superstition and magic. A counter-narrative sees in this process only the subordination of visceral, creative pluralism to soulless reason. The quarrel turns on a shared set of opposed pairs: reason versus passion, fact versus opinion, neutral versus partisan – reason versus rhetoric. This opposition underplays the extent to which rhetoric, as a classical discipline, was concerned with the ways in which audiences could be swayed through a combination of both reason and emotion. The epistemological significance of a consideration of rhetoric does not, therefore, lie in completely debunking the idea of truth. Rather, it requires a rethinking of the idea that the task of knowledge is for an observer to represent an independent external reality in a transparent medium: rhetoric’s concern with the joint, shared aspects of gaining assent and persuading others suggests a contextual account of the justification of knowledge and belief (see also EPistemology).

In GEOGRAPHY, rhetoric has become a focus of attention in the wake of a more general revival of interest in this topic in PHILOSOPHY, anthropology, linguistics, literary studies and history (White, 1978; Clifford and Marcus, 1986; Nelson, Megill and McCloskey, 1987). This engagement has led to a greater degree of reflexivity towards the rhetorical strategies prevalent in the discipline, and how these inscribe particular orientations to audiences and publics. But geography’s treatment of rhetoric has tended to fall into the familiar oppositional pattern noted above. The characteristic reduction of rhetoric to metaphor reinstalls the world/word binary. Interest in rhetoric has therefore been mainly restricted to debunking of the truth-claims of various research fields, as a kind of renewed IDEOLOGY-critique. On this view, the rediscovery of rhetoric helps us to see that all orthodoxies and norms are really just contingent constructs, whose reproduction is neither natural nor reasonable, but is really the effect of rhetorical strategies as part of political agendas.

There remain two areas in which a consideration of rhetoric might still have a creative impact on research agendas in HUMAN GEOGRAPHY. First, the rhetorical-responsive account of action, practice and subjectivity developed by Shotter (1993), and building on the tradition of Gilbert Austin, Mikhail Bakhtin, Kenneth Burke, Rom Harré, Paul Ricoeur, Lev Vygotsky, Ludwig Wittgenstein and others, retains its potential for redeeming the concept of discourse from the prevalent representational construal to which it has been subjected in geography, by returning it to a fuller sense of language-in-use and language-oriented-to-action (cf. REPRESENTATION). This in turn would have implications for methodological analysis of both archival data and talk-data generated in FOCUS GROUPS, INTERVIEWS and ethnographic situations (see ETHNOGRAPHY). Second, understanding rhetoric as the effort to move and affect audiences through various modes of appeal and persuasion points towards an alternative approach to the analysis of PUBLIC SPACE that investigates the different types of rhetorical force that are deployed to convene publics (Barnett, 2007).

rhizome Botanically, a rhizome is an underground system of stalks, nodes and roots through which a plant spreads horizontally and sends out new shoots. The METAPHORICAL use of the term has been associated with the philosophy of Gilles Deleuze and Félix Guattari (1987). For them, that which is rhizomatic is counterposed to that which is arborescent, or tree-like. Unlike vertical and hierarchical arboREAL structures, rhizomes are comprised of non-hierarchical NETWORKS within which there are many ways to proceed from one point to another. According to Deleuze and Guattari, such rhizomatic networks are resistant to and disruptive of ordered vertical and thus striated spaces, such as those of the STATE (see also POST-STRUCTURALISM).
rhythmanalysis A term coined by the French Marxist Henri Lefebvre (1901–91) to describe a mode of analysis characterized by its receptivity to temporal dimensions, particularly moments, cycles, tempo, repetition and difference (see TIME). Lefebvre (2004 [1992]) is concerned not merely with the analysis of rhythms – bodily, social, daily, seasonal, lunar – but also analysis through rhythm. In the latter case he is particularly interested in the way in which the study of rhythms can shed light on the workings of the modern city, everyday life, the body and capitalist production. Lefebvre shows how space and time need to be thought together rather than separately, and how a non-linear conception of time and history is a crucial balance to his famous rethinking of the production of space. Lefebvre’s conception of rhythmanalysis may be contrasted with the more mechanical, high modernist conceptualizations of Torsten Hägerstrand’s time-geography, but also can be profitably related to Ermarth’s (1992) account of the crisis of representational time under postmodernism (cf. representation) and her own, quintessentially rhythmic sensibility that emphasizes repetition and pulse rather than linear sequence.

ribbon development Development strung along major roads within, on the edges of, or stretching beyond urban areas. It is generally associated with commercial establishments looking for cheap, easily accessible sites with high visibility to large volumes of passing automobile traffic. Ribbon developments are perhaps epitomized by the classic American ‘highway strip’, where development is often no more than one block deep on each side of the road. Celebrated by some as classic Americana, as worthwhile vernacular architecture, or as the spatial manifestation of market forces, ribbon development is increasingly criticized as an element of socially, economically and environmentally problematic urban sprawl.

rights A right is a power or privilege to which one is justly entitled. Rights are often distinguished from duties (i.e. the behaviour expected of others, including the state) and privileges (that which can be conferred or invoked). Rights presuppose corresponding obligations upon others to do something, or to refrain from doing something. My right to freedom of speech, for example, requires the state to abstain from summarily repressing my speech. Rights are capable of several meanings, depending upon the context within which they are put to work. So, for example, moral and formal/legal rights may differ.

Within national jurisdictions (cf. HUMAN RIGHTS), formal rights can be subdivided. Civil rights refer to those entitlements of personal liberty given to all citizens by law (such as property rights, freedom of association, religion, movement, and protection from arbitrary arrest). Political rights are those that bear on the establishment and operation of the state, such as the right to vote. Social rights entail the entitlements of citizens to social benefits, such as health or education. The political priority accorded these different rights and their intersection is, of course, a crucial issue for any political community. Debate also turns on which entities can be legal rights-holders: Are we to include children? Animals? The insane? Ecosystems?

Rights are central to both statecraft and social life, and have become a standard feature of the constitutional apparatus of the modern state. Rights-claims carry special force: in ascribing rights to certain social relations, we ‘shift them out of the realm of the merely desirable and into the domain of the morally essential’ (Jones, 1995, p. 4). For Laclau and Mouffe (1985), a vocabulary of rights allows for the politicization of power relations. That which had been cast as subordination (i.e. as something that appeared natural and unchanging) can be reframed as oppression (i.e. unjust and contingent).

However, others worry at the ways in which rights can cast political subjectivity in particular and limited ways, and reproduce contingent visions of the social and political world. For this reason, argues one strain of critical scholarship, we should be sceptical of the progressive potential of rights. Others counter by arguing that rights are ‘protean and irresolute signifiers’ (Brown 1997b, p. 86), whose varying and often expansionary meanings can be put to work in diverse political sites.

What, then, of the geography of rights? It is clear that space shapes the ways in which rights are construed, contested and put to work (Blomley, 1994; Blomley and Pratt, 2001). Liberal rights (see liberalisms), most particularly, help produce, and operate within, sharply demarcated spaces. The way this ‘sociopolitical map’ (Walzer, 1984, p. 315) is produced
may affect the ways in which subjectivity is produced, as well as shaping the political possibilities associated with rights (Marston, 2004b).

As Pratt (2004) argues, spatial REPRESENTATION can be used to close rights down as well as open them up. Representations of the spaces of the body, the public–private divide (see PRIVATE AND PUBLIC SPHERES) and the NATION can all serve to delimit or deny rights. And yet, Pratt argues, activists seeking to advance rights-based claims in defence of Filipino domestic workers within Canada have put other spatial representations – such as SCALE, international HUMAN RIGHTS and the ‘empty space’ of liberal universalism – to productive work. At an extreme, the peripheral and exclusionary locations to which marginalized groups have been assigned can also be used as a space from which to contest and challenge the ordering of rights (Chouinard, 2001; Peake and Ray, 2001).

The relation between rights and space takes on a particular dimension when it comes to PUBLIC SPACE. Public space is historically predicated on particular and related forms of territorial exclusion, with only certain subjects being deemed appropriate rights-bearers in relation, in part, to the degree to which they were imagined as fully formed citizens (see CITIZENSHIP). Yet public space, Don Mitchell (2003, p. 29) argues, is a site made through political struggle, as outsider groups, such as women, the working class and ethnic minorities, have fought their way into the public realm. Such a struggle necessarily entails rights. Again, rights can be used to deny public space to certain populations or can be used as a tool to pry public space, and thus, citizenship, open. Both rights and space, then, are said to be co-produced: social action ‘always operates simultaneously to influence the production of law and the production of space’ (Mitchell, 2003a).

It is because of the political valence of rights, and their spatiality, that geographers have become interested in rights in more than a descriptive sense. Lefebvre’s (1996) call for a ‘right to the city’ has been invoked by those who seek to articulate a normative vision of space and social justice (Harvey, 2000b). However, much of this work, while interesting and even inspirational, remains under-theorized, and fails to engage the broader critical literature on rights, their politics and their geographies.

**Risk**  In the first, technical, sense, risk refers to the probability of a known event (which may be a cost or a benefit) occurring. Such probabilities assume that causes and consequences can be determined, mapped and predicted. This is a highly rationalist endeavour characteristic of MODERNITY and a belief in controllability. Risk in this sense is about knowing the world, and is therefore not subject to uncertainty or indeterminacy. In order for such a probability to be calculated, the risk must be first identified (e.g. failure of an aircraft engine, the development of lung cancer, leakage of radioactive waste). The pathways to the event also need to be identified, and the likelihood of such pathways and events occurring needs to be calculated. The latter will often require some element of technical knowledge, but also an understanding of the social and institutional relations that surround a risk (e.g. the ability of a regulatory body to police possible risk pathways). In certain circumstances, probabilities can be calculated from past events (the chances of developing lung cancer from smoking can be estimated from population data). In other circumstances, where events are uncommon or where new technologies mean that there are few if any precedents, determining risk becomes more and more contentious. Not only are the occurrences or manifest dangers/benefits difficult to second-guess, but the pathways to them may be impossible to imagine prior to the event, and the institutions responsible for regulating behaviour may not be sufficiently established or experienced. Meanwhile, given the geographical, material and social complexities of everything from taking a drug to building a nuclear power station, the ability to calculate risk becomes ever more fraught with uncertainty and indeterminacy. The growing sense of the non-calculability of risks feeds in to a second, more qualitative, sense of risk. Here, risk takes on a meaning that has more akin with uncontrollability and danger. Most effectively taken up in Beck’s Risk society (1992) and Mary Douglas’ anthropology of risk and blame (Douglas, 1992), risk becomes a contestable issue in society at large. All calculations become liable to re-calculation or to rendering non-calculable. Controversies over risk become more and more common as various individuals and bodies contest each other’s estimation of events and pathways, and dispute the ability of responsible or regulatory bodies to shepherd technologies, processes and markets in such a way as to minimize risk (the ongoing battles over the

environmental and human safety or otherwise of genetically modified foods is a case in point (Bingham and Blackmore, 2003). The latter, institutional, element to risk debates has been taken up most effectively by those researchers who have investigated the dynamics of trust relationships between (expert) responsible bodies and (lay) publics (Wynne, 1992, 1996). At the same time, and partly on account of the inevitably of ‘not knowing’, risk enters the vernacular as something that should be encouraged, for if risks are not taken then nothing creative or new can be generated. Nevertheless, as Douglas (1992) and Lupton (1999) have argued, risk increasingly refers to the dangers, threats and contingencies of actions. (See also biosecurity; security.)
rural geography The superstructure of modern academic geography was thoroughly metropolitan – London, Paris, Berlin, Chicago – but its foundations were in the countryside. Paul Vidal de la Blache developed his regional geography through close (though not exclusive) attention to the peasant cultures of rural France, for example, while Carl Ortwin Sauer’s vision of cultural geography focused on the evolution of rural and agrarian landscapes in the Americas. Even early location theory and spatial science looked to the countryside for their origins: von Thünen’s model of agricultural land use was based on records from his country estate, Christaller’s central place theory was rooted in a stable world of southern Bavarian marketplaces rather than explosive urban–industrial growth, and Torsten Hägerstrand’s diffusion theory grew out of his studies of the Swedish countryside. But the distinction between city and countryside is a culturally constructed one (Williams, 1973), and there is an important tradition of historical geography in Europe and North America that has long been concerned with reconstructing its historical transformations (e.g. the work of the Permanente European Conference for the Study of the Rural Landscape, established in 1957: see http://www.pecsrl.org).

No less importantly, the distinction also varies over space. In Europe, and particularly in Britain, rural geography has recently been reinvigorated as a response to a series of political and cultural concerns: the ‘threat to the countryside’ and to wildlife posed by urbanization, the transformation of agriculture and the aggressive rise of agribusiness (see also agricultural geography), the rise of new modes of recreation and the development of ‘second homes’ in the countryside, the changing class composition of rural communities, and the ways in which all these issues are entangled in wider debates about the politics and production of nature. These politico-intellectual responses have challenged the concept of rurality (Marsden, Murdoch, Lowe, Munton and Flynn, 1993; Cloke, 2006) and increasingly treated the rural as a series of cultural constructs rather than a set of geographically bounded spaces (Murdoch, 2003). In North America there have been comparable, historically sensitive studies of the exploitations and oppressions embedded in the production of agrarian landscapes (Mitchell, 1996) and of the imaginative geographies through which they have been domesticated, notably in literature and film (Henderson, 1999), though probably few of those responsible would situate their work within a distinctively rural geography. Similarly, some of the most exciting work in political ecology and environmental studies in America – Kosek’s (2006) analysis of New Mexico’s forests, Sayre’s (2002) accounts of ranching in the Southwest, Hollander’s history of the Everglades (2008) – has taken as its theatre of operations the rural broadly construed.

Still more generally, the classic agrarian question has directed attention to the differentiation of rural producers, the contribution of the rural sector to capitalist accumulation, and the politics of class distinctions in the countrysides of the global south. Here, the vast literature on peasants has rarely attempted to theorize rurality but has instead preferred to focus on social differentiation, the organization of work and household dynamics (Bassett, 2001; Gidwani, 2008). Analysis of the so-called urban bias (Lipton, 1977) and of rural–urban linkages has been especially fruitful in generating new questions about the formation of complex, hybrid urban–rural spaces (McGee, 1991) and about power, patronage politics and differential forms of accumulation across space (Hart, 2002; Chari, 2004). The World Bank’s World Development Report for 2008 notes that ‘three out of every four poor people in developing countries live in rural areas – 2.1 billion living on less than $2 a day, and 880 million on less than $1 a day – and most depend on agriculture for their livelihoods’. It also notes that rural poverty has declined over the past twenty years in East Asia and the Pacific, largely the result of improving conditions in the countryside rather than out-migration, but that the number of rural poor has continued to rise in South Asia and sub-Saharan Africa. A distinguishing characteristic of rural poverty is its disproportionate toll on women and the exposure of the rural workforce to the fragmentation of labour markets, and the impermanence and seasonality of labour contracts. Indeed, one of the central findings of the report is the extent to which agricultural populations are dependent upon off-farm income, in which the structure of the rural, non-agricultural economy is crucial. The questions that dominate rural geographies in these regions include drought, famine and global climate change (Watts, 1983a; see global warming); the production of food and access to water; dispossession and the politics of development; the violence of resource wars and other forms of
late-modern war; and the state regulation of migrancy and mobility. These issues are urgent reminders that the production and transformation of the rural is by no means confined to the global North and is everywhere enmeshed with globalization (cf. Woods, 2007; McCarthy, 2008). Despite the predictions of the imminent demise of the peasantry in the global South and the depopulation of the countryside in the North, the rural continues to be a site of political contestation, from debates over the agricultural policy of the European Union to the resurgence of rural protest in China.

rural planning The attempt to organize and control the distribution of development and resources across rural areas: concerns include the management of land-use change (see land use and land-cover change) in relation to the built and some aspects of the natural environment, as well as economic and social issues.

Rural planning in the developed world has two main functions: first, the strategic allocation of development through the production of frameworks and principles for resource distribution and conservation; and, second, the control of the alteration, growth and design of the built form (cf. zoning). Tensions have frequently arisen in planning for rural areas between the many demands on rural land, particularly in the context of the changing importance of farming and food production. In addition, pressure from counter-urbanization in many parts of the developed world has introduced conflicts within rural planning between the desire to conserve the natural environment and provide housing in desirable residential areas. In some rural areas, land-use designations such as national parks have sought to maintain tight control on development and resource use in the most valued environments. In developing countries, emphasis is placed less on control but, rather, on the generation of economic growth in the distribution of resources and the organization of agricultural development.

The study of rural planning during the 1970s and early 1980s was largely descriptive and uncritical. From the late 1980s, however, greater attention was paid to the power relations within which planning operated, including the influence of social class over the allocation of resources and the broader strategic direction of the planning process (Cloke and Little, 1990). Particular attention was given to the role of environmental politics in shaping planning agendas and outcomes (Williams, 2001). More recently, these discussions have been set within understandings of the shifting nature of governance within rural communities and of the relevance of new decision-making structures and responsibilities (Goodwin, 1998). Work on the emergence of new forms of rural politics has also helped to inform contemporary research on rural planning (see Woods, 2006).

rural–urban continuum A once-popular hypothesized continuous gradation of ways of life between rural areas and large cities. It assumed a polarization of attitudes and behaviours between ideal rural situations, on the one hand – characterized by communities built around kinship, attachment to place and co-operation (what To¨nnies (1955) referred to as Gemeinschaft) – and large cities, on the other – characterized by societies dominated by impersonal, especially market, relationships (Gesellschaft). Although some empirical studies found patterns consistent with the hypothesis, it was largely demolished by studies – such as Pahl’s (1965) – that identified village-like communities within cities and urban traits spreading into the countryside.

rustbelt A descriptive term for the area of declining manufacturing industries in the north-east of the USA, now more widely applied to any area of industrial decline (cf. sunbelt/snowbelt).
sacred and profane space

Sacred spaces are sites imbued with a transcendent spiritual quality. They are characterized by the rituals people practice at the site, or direct towards it. Mircea Eliade, the scholar of comparative religion most closely associated with the concept of sacred space, proposed that it is with sacred experience that sacred space is marked out from profane space. Whereas profane experience maintains the homogeneity of space, the sacred disrupts that, creating non-homogeneous space (which is why sacred space figures so prominently in discussions of urban origins).

Eliade (1959, pp. 26–7) identified three ways in which sacred places are formed: when there is a hierophany (an ‘act of manifestation of the sacred’, such as a voice proclaiming the sacredness of a place); an unsolicited sign indicating the sacredness of a place (as when something that does not belong to this world manifests itself); or a provoked sign (e.g. using animals to help show what place or orientation to choose in setting up a village). Sacred places may also be made through the relics of holy beings.

Sacred places may occur in bio-physical or in built form. Animists, in particular, believe that some form of the divine exists in nature, though this is true too of some world religions. Thus, rivers, trees and mountains are religiously interpreted, and invested with symbolic meanings. For example, the bodhi tree is a sacred tree for the Buddhists, while the Ganges River is venerated by the Hindus. In built form, perhaps the most visible and obvious sacred spaces are the ‘officially sacred’ (Leiris, 1938) religious buildings, such as churches, temples and synagogues, though roadside shrines and home altars constitute other examples of sacred spaces too. In advanced technological societies, technoreligious spaces such as radio and television broadcasts and Internet-based communication also contribute to the making of sacred experiences through live telecasts of prayers and religious gatherings, for example, thus creating new conceptions of sacred space.

Chidester and Linenthal (1995, p. 6) argue that ‘nothing is inherently sacred’. Sacred space is contested space. It is ‘not merely discovered, or founded, or constructed; it is claimed, owned, and operated by people advancing specific interests’ (ibid., p. 15), involving ‘hierarchical power relations of domination and subordination, inclusion and exclusion, appropriation and dispossession’ (ibid., p. 17). In these power relations, four kinds of politics are apparent (van der Leeuw, 1986 [1933]): a politics of position whereby every establishment of a sacred place is a conquest of space; a politics of property whereby a sacred place is ‘appropriated, possessed and, owned’; a politics of social exclusion, whereby the sanctity of sacred place is preserved by maintaining boundaries; and a politics of exile, which takes the form of a modern loss of or nostalgia for the sacred.

Sacred spaces need not always be sacred. The same space may be sacred at one time under one set of circumstances, but not sacred at other times and circumstances. For example, a house is ordinarily considered functional space, but in its design and the rituals practiced within, it may become sacralized.

sampling

Sampling involves selection from a greater whole and can be contrasted with a full enumeration or a census. However, even when a census has been undertaken, the outcomes can still be regarded as a sample of what could have occurred (another stochastic realization) – for example, on other than census day – so the concept of sampling has even wider applicability. It is an essential part of extensive research designs and survey analysis, but is also important when qualitative data are collected and interpreted (King, Keohane and Verba, 1994). The most common reasons for sampling are the costs of measuring an entire population and the unethical intrusiveness of doing so.

Any sampling strategy is concerned with estimating an unknown parameter (such as the proportion in poverty, the mean income, or the total number in poverty) and its likely error, and involves trade-offs among:

- Representation: the ability to generalize from the sample to the (carefully defined) wider population.
Coherence: the degree that the measured entity conforms to the theoretical construct being studied. This is particularly important in qualitative research when often necessarily small samples need to be theoretically relevant (Mitchell, 1983); consequently, for example, we need to define and sample the different mechanisms that place people in poverty (exclusion from the job market, divorce and separation, etc.) and make sure that each type is recognized and studied.

Bias: the degree to which the parameter is accurately estimated, without systematic error; for example an Internet-based sampling strategy may seriously underestimate the extent of poverty.

Precision: the degree to which the parameter is reliably measured and random, stochastic, innumerable small errors are controlled.

Efficiency and cost: efficiency is the relative precision of an unbiased sample compared to others of the same size. Concern with precision can often be over-ridden by convenience, practicality and cost; moreover, it is generally much better to do a well-designed small-scale study than a botched large-scale one.

A highly convenient sample design (often used by commercial organizations) is the quota method, in which, for example, an interviewer approaches people on a shopping street until the desired quota of 25 each of young and old men and women is reached. This approach is simple but also open to bias, as certain types of people are not generally found in shopping streets; there can also be interviewer bias, as the interviewer may be resistant to approaching certain groups of individuals. Non-response is inevitably ignored in this approach. Snowball sampling is when having found a key informant (e.g. a drug user) they are asked to recommend others. While useful with hard-to-reach populations, there is again the potential for bias as isolated drug users may be missed and one circle of users may not intermix with others. A systematic sample is when respondents are chosen in an ordered way, such as every fourth house on a street. Such a design is highly convenient in an the field and when the total population is not known, but can produce biased results when the entity being studied has a corresponding systematic patterning, so that all even-numbered houses on one side of a street are social housing, but all odd-numbered houses are owner occupiers.

All the designs discussed so far are non-probabilistic. In probabilistic designs the key feature is that neither the interviewer nor the interviewed can affect the selection mechanism, which is done at random. With such samples, the likelihood of being sampled is knowable and non-zero; consequently we can use statistical theory (based on the central limit theorem) to guarantee unbiased, representative estimates and to estimate the degree of precision in those estimates. Thus we can say that the proportion in poverty is 25 per cent and that we can be 95 per cent confident, given our sample of 7,200 households, that the true underlying rate lies between 24 and 26 per cent. Non-probabilistic sampling is not necessarily biased and unrepresentative, but we lack the necessary formal framework for making any judgement.

There are three basic types of probabilistic sample:

Simple random sample (SRS) requires a complete listing of the population (the sampling frame) from which a sample is chosen at random so that each and every unit has an equal chance of being selected. With such EPSEM sampling (equal probability of selection method) the standard error, which defines the precision of the sample estimate, is proportional to the square root of the absolute sample size. Consequently, the larger the sample (in absolute terms, not as a percentage of the population) the greater the precision but there are diminishing returns, as the sample size must be quadrupled to halve the standard error. This can be an expensive design as in a national survey the interviewers will be required to travel the entire country. In practice, quasi-random samples are often used; for example, the British national birth cohorts of 1946, 1958 and 1970 were based on babies born in a particular week, while the ONS Longitudinal Study uses record linkage of individuals born on four days of a year, which equates to some 1 per cent of the national population. Indeed, providing there is no periodicity in the sampled variable, systematic sampling can be treated as quasi-random. With probabilistic sampling, an effective sample size of 10,000 respondents is needed in order to be 95 per cent confident of being ±1 per cent of the true value, when that is 0.5. Typically, scientifically credible national opinion polls contain around 1,500 respondents. In student and
other small projects, the absolute minimum is 100 and preferably 250 when subgroups (male and female; young and old) are being analysed. The aim should be a focused QUESTIONNAIRE to a lot of people, rather than a long questionnaire to few, or a recourse to SECONDARY DATA.

- **Stratified sampling** groups the population into strata so as to maximize similarity within a stratum and maximize between-strata differences. This can considerably increase the sample’s efficiency if stratification is based on a variable strongly related to the estimate. If income is strongly related to region, then regions could be used for stratifying and reducing the standard error of the mean income estimate. We used for stratifying and reducing the standard error of the mean income estimate. We can also disproportionately sample from particular strata when there are important groups of the population that are numerically small and so would yield only small numbers if SRS were used within strata such as ethnic groups (see ETHNICITY) with the non-indigenous groups over-sampled to get more precise estimates. Such a strategy requires detailed knowledge of the sample frame in terms of an ethnic classification, and the analysis should be weighted to get correct estimates.

- **Multi-stage designs** involve sampling in stages. For example, a sample of constituencies may be selected at random (the so-called primary sampling units), then wards within them, then HOUSEHOLDS within wards and individuals within households. This design is often used for major scientific surveys, as it only requires a sampling frame at each stage; thus at stage one only a list of constituencies is required, while at stage two, only ward names are required for those constituencies already selected. Another advantage is the cost reduction resulting from basing a team of interviewers in the higher-level units. A variant is the cluster design when at some stage all the lower level units are sampled — everybody in a ward is selected, for example. A problem with these designs is that there is a tendency for people living in the same place to be somewhat similar so that the resultant sample is more alike than a random sample and standard statistical theory gives overly precise results. Clustered data lead to inefficiency and it is not unknown for an SRS a third of the size to achieve the same standard error. It is clearly vital to measure this dependency (the intra-class correlation) and correct for it. The development of MULTI-LEVEL MODELS allows this even when the sample is unbalanced with a different number of units in each higher level unit. Consequently, multistage designs are recommended for studying variation simultaneously at a number of different SCALES, with the population itself seen as having a hierarchical structure, which is itself of substantive interest (Jones, 1997). Indeed highly clustered designs are needed if survey information is to be gathered on individuals as well as their peers. With such designs, it is necessary to specify the number of units at each level; Raudenbush and Xiaofeng (2000) provide the necessary background, which is put into practice by Stoker and Bowers (2002) in their geographically sensitive designs for surveying American voting behaviour.

These three designs can be used in combination; the UK Millennium Cohort study, unlike previous birth cohorts, is spatially clustered specifically to study NEIGHBOURHOOD EFFECTS. Wards are disproportionately stratified to ensure adequate representation of all four UK countries, deprived areas and areas with high concentrations of particular ethnic groups, and then all babies aged 9 months in selected wards over a 12-month period. The resultant sample includes 19,000 infants who are being followed longitudinally.

Other probabilistic designs may be used for different circumstances; they include CAPTURE-RECAPTURE METHODS to estimate population size with mobile populations, and response-based sampling (see EXTENSIVE DESIGNS) when a numerically small but important outcome is over-sampled. In geographical studies, the standard procedures may be modified to ensure spatial coverage. Methods of random, systematic and stratified sampling of points on a MAP have been devised using coordinate systems, for example, as have methods of selecting transects (line samples) across an area (Berry and Baker, 1968). Increasingly, these designs are being used adaptively (Thompson and Seber, 2002), so that the degree of SPATIAL AUTOCORRELATION is being assessed as the survey proceeds and there is increased sampling in areas where the outcome variable is most varied and least spatially dependent.

When testing a HYPOTHESIS it is crucial to assess and control for two types of error in a probabilistic design. Type I errors, finding an effect when there really is none, are controlled
SATISFICING BEHAVIOUR

by setting demanding probability levels in CONFIRMATORY DATA ANALYSIS. Type II errors – that is, having insufficient information to be able to detect a genuine effect – are managed by conducting a power analysis during the design phase. Conversely, collecting too much information is not only wasteful of resources but can be seen as an unethical intrusion. Statistical power is increased when there is little ‘noise’ in the system; the effect is substantial when probability levels are set leniently and when the sample size is large, and according to which statistical test is used (parametric procedures being more powerful). Consequently, researchers should choose settings/contexts that maximize the ‘signal’ and not as in a study of the effect of size of house on price, sample areas where all the properties are three-bedroomed ones. Power formulas and software (such as G*Power) are available but require an estimate of the size of the effect. Cohen (1988) has defined small, medium and large effects as the ratio of an effect to variation for a very large range of statistical procedures (e.g. a t-test in a multiple regression model). Thus, to be able to detect a small difference of 0.25 of a standard deviation between two sample means with 80 per cent power and 5 per cent significance (both these percentages being the most commonly used conventions) requires 2,253 observations in the total sample; while to be able to detect a large difference of 1.0 standard deviation requires only 2,17 observations. Unfortunately, academic research has paid too little attention to statistical power with, for example, Sedlmeier and Gigerenzer (1989) finding that even in a reputed journal statistical power hovered around 50 per cent. If all these studies were replicated, only half would result in an identifiable effect. The problem is actually even more widespread due to the use of non-probabilistic samples. The way forward is to use SIMULATION to judge effectiveness and efficiency, as pioneered by Snijders (1992) for snowball sampling. Indeed, simulation is a general strategy that permits great flexibility, not only allowing the assessment of power as sample size increases but also catering for missing data, non-linearity, unequal variances and other specifications of an underlying model.

satisficing behaviour Behaviour that meets an actor’s minimum criteria for success. The concept was developed by Herbert Simon (1916–2001: see Simon, 1956) as an alternative to the presumed OPTIMIZATION of RATIONAL CHOICE THEORY, in which actors always seek to make the best-possible choice – for example, to maximize profits. Satisficing behaviour may be appropriate either when it is impossible to calculate the maximal outcome or when actors are unprepared to make the investment necessary to identify and/or pursue that outcome (as argued by Pred, 1967, 1969). Actors will then set their own criteria that will represent a satisfactory return on their investment. (See also BEHAVIOURAL GEOGRAPHY.) RJ

scale ‘Scale’ has no single definition, and in recent years has been the object of much theorizing (Howitt, 2003). The traditional definition in CARTOGRAPHY refers to MAP resolution. All maps represent the world by reducing the size and diversity of its component spaces for visual display, digitally or on paper. Cartographic scale expresses the mathematical relationship between the map and the Earth, usually denoted as a representative fraction. For example, the small fraction, 1:500,000, indicates that one unit of distance on the map represents 500,000 units of Earth space. Such a map would show large expanses of terrain – much more than say, the larger fraction of 1:24,000. Hence the common confusion between large-scale (or large-fraction) maps that show less space but typically more detail, and small-scale maps that show more space, but with less detail. Each type of social and environmental diversity has its own ‘best resolution’ in terms of cartographic REPRESENTATION; thus, the choice of cartographic scale depends on the problem at hand. To visualize US state variation in the enforcement of environmental policies, we need the familiar small-scale map of the country with state borders, while determining whether point source POLLUTION released into a river caused downstream lymphomas requires a large-scale map.

The second major definition is operational or METHODOLOGICAL. This is the scale or resolution of data collection, with the familiar cascade from micro (BODY) to macro (GLOBE). Tied to this type of scale are various analytical complexities, including the claims that: (a) social patterns and processes can be sorted according to their scale of operation and, as
a result, it is important to ensure an appropriate match between research questions and the scale of analysis when developing a research design (see ecological fallacy); (b) some processes may operate at multiple scales at once, and as a result, attention should be paid to their operational distinctiveness at particular scales and to the mechanisms that define their modifications from one resolution to the next; and (c) any scaled process can intersect with other processes operating at any other scale, often in complex ways that attenuate, amplify or destabilize their operation. These sorts of causal complications, in which processes are conceived not only in their own terms but also in terms of their scales of operation, form one of the more powerful arguments for the necessity of incorporating space into social science. It is also here that one finds common ground between human geography and physical geography, for both deal with scalar shifts in processes. In the study of coupled social and natural systems, the complications of (a) to (c) above may be operative.

A third aspect of scale is to recognize what has been variously called its social production or social construction (Smith, N., 1992b; Delaney and Leitner, 1997; Marston, 2000). In this view, spatial scales do not, as implied above, rest as fixed platforms for social activity and processes that connect up or down to other hierarchical levels, but are instead outcomes of those activities and processes, to which they in turn contribute through a spatially uneven and temporally unfolding dynamic (Swyngedouw, 1997). This recursive relationship between social processes producing scales and scales affecting the operation of social processes is one aspect of the socio-spatial dialectic: the idea that social processes and space – and hence scales – mutually intersect, constitute, and rebound upon one another in an inseparable chain of determinations (see production of space). Over the past two decades, this view of scale has generated some of the most productive and novel research in human geography (Cox, 1997; Herod and Wright, 2002).

Given the importance of the dialectic to historical materialism (and the larger corpus of marxism) in general, and to marxist geography in particular, it was capitalism that was early on identified as the driver behind the production of scale. From the formation of working-class neighbourhoods whose residents defend ‘turf’ through misplaced parochialisms, to the elite spaces of cosmopolitan jet-setters who shirk their ethical responsibilities while working to expand the world economy, the inherently uneven development of capitalism has been viewed as the fulcrum of the production of scale. This emphasis led Marston (2000) to critique this body of research for its privileging of production and its relative neglect of social reproduction. There nevertheless remain several key advances in this literature, including: (a) an acknowledgement of the inherently political nature of scale production (Smith, 1996a); (b) the need to pay attention to state formations and various resistance movements that both deploy and construct scales (Miller, 2000; Brenner, 2004); and (c) the need to re-theorize in more complex ways the relationship between social processes and spatial outcomes as power comes to be understood as dispersed rather than centred. It is in part through this last point that several scale theorists over the past several years have begun to turn away from purely hierarchical — or, we might say, vertical — understandings of scale to incorporate formulations that resemble the horizontal relations of networks (Amin, 2002b; Brenner, 2004).

The latest debate revolves around the claim that scale itself, while no doubt an organizing moment in epistemology, has merely a transcendent status within the domain of ontology (Marston, Jones and Woodward, 2005). In the view of Marston and her colleagues, scale is an epistemology that, though potentially helpful in a methodological sense, is tied
to a global-to-local continuum that underwrites the problematic view that social processes can be detached from the grounded sites where people and objects concretely reside and social practices take place (e.g. in streets, bedrooms, boardrooms). They offer in its place a flat ontology that resists conceptualizing processes as operating at scales that hover above these sites (e.g. metropolitan regions, nation-states). This view continues to generate much debate (e.g. Leitner and Miller, 2007; Jones, Woodward and Marston, 2007).

Science/science studies

Science is an ‘essentially contested concept’ (Gallie, 1964) in the sense that it defies specification in terms of necessary and sufficient conditions. Numerous candidates have been offered by PHILOSOPHY to discriminate science from non-science – knowledge based on first-hand observation, claims and procedures warranted by predictive success, the inductive gathering of empirical data, information satisfying the principles of verification or falsification, and so on. The efforts of Copernicus and Galileo to base knowledge on causal explanations rather than Aristotelian syllogism, Bacon’s plea for inaugurating the method of INDUCTION, Newton’s rejection of speculative hypotheses in favour of his own method of deduction (see HYPOTHESIS), the Logical Positivists’ emphasis on the logical structure of theories (see LOGICAL POSITIVISM), and Lakatos’ defence of what he called ‘the methodology of scientific research programmes’ constitute just a few of the proposals that have been made to place science on secure foundations (Oldroyd, 1986). But none of these have been adequate to catch the presumed essential features of enterprises that stretch temporally from Aristotle to Einstein, cognitively from astronomy to zoology, and spatially from medieval Arabic geodesy to Enlightenment Scottish chemistry. This recognition has led to what Larry Laudan (1988) has aptly termed ‘the demise of the demarcation problem’. Uncontested mapping of the border between science and other forms of human cultural activity (see CULTURE) has simply remained elusive.

Nevertheless, the label ‘science’ does refer to a suite of enterprises sharing some family resemblance with the kinds of observational and experimental practices that came to characterize natural philosophy during the period of the seventeenth and eighteenth centuries (see SCIENTIFIC REVOLUTION(S)). And it was in that era that the term itself began to acquire a definition that linked it to a body of demonstrated truths and observed facts brought into coherence by their adherence to general natural laws. As Watts put it in 1725 (2, ii, §9), the word ‘science’ was ‘usually applied to a whole body of regular or methodical observations or propositions’.

GEOGRAPHY’s engagements with the scientific tradition have been multi-faceted. Terminologically, the label ‘scientist’ has close associations with geography via Mary Somerville, whose Physical geography of 1848 firmly staked geography’s claims to scientific status. In fact, it was in a review of one of her earlier books that the word ‘scientist’ was first coined by William Whewell (that irrepressible neologist), although it did not circulate into common currency until the 1870s. Historiographically, insights from the philosophy and history of science have been used by a range of geographers to interpret the evolution of their own tradition of enquiry (see GEOGRAPHY, HISTORY OF). In particular, the perspective of Thomas Kuhn on the structure of scientific revolutions has been the subject of discussion within the discipline as to the extent to which it throws light on Geography’s lineage (see also PARADIGM).

In two other substantive ways, Geography and science are tightly interwoven. First, geographical practice has routinely – though certainly not universally – adopted scientific techniques and vocabulary, and not just in PHYSICAL GEOGRAPHY with its evident roots in both field and LABORATORY science. Thus during the period of the Scientific Revolution, for example, mathematical advances were used to solve problems of MAP PROJECTION, and the subject was routinely taught in association with astronomy. In the same period, Varenius’ Geographia generalis of 1650 advanced his own version of the mechanical philosophy to contest Aristotelianism, and William Petty began to apply the methods of the new natural philosophy to social phenomena with his development of ‘political arithmetick’. Navigational expertise, requiring computational skills and knowledge of observational astronomy, was also often taught in geography courses (Livingstone, 2003b). Such projects firmly linked geography as an enterprise to practical mathematics and the scientific tradition, and this impulse has continued to
animate various strands of modern geography. During the 1960s, some geographers with scientific aspirations turned to the language of logical positivism to underwrite (after the event, as a matter of fact) their project to create a spatial science grounded in natural laws of spatial relations and expressed in numerical language (see locational analysis; quantitative revolution). Critics of this trajectory accused its practitioners of indifference to questions of social inequity, a lack of political engagement, and an inclination to use mathematical vernacular as a shield to deflect establishment suspicion of social science during the McCarthy era (Harvey, 1984) – though some of its advocates, such as William Bunge, mobilized spatial statistics for radical purposes.

More recently, geographers have begun to bring science within the discipline's scope both by deploying the insights and methodologies of science studies and by enquiring into the spatiality of science as itself a cultural practice (Livingstone, 2003a). As an enterprise, science studies largely developed in the wake of Kuhn's rejection of purely logical models of scientific development and his insistence that scientific change was inherently discontinuous. By allowing a variety of social–communal factors into the understanding of the evolution of science, by emphasizing the underetermination of theory by empirical data and by highlighting the role of tacit knowledge in scientific practice, Kuhn opened the door to empirical studies of scientific procedure. While he himself expressed concern about more extreme versions of relativism, his work did open the door to the social history of science. This project has taken various forms, notably the so-called Edinburgh ‘strong programme’ associated with writers such as Steven Shapin and David Bloor, which sought to locate the cognitive claims of science in its wider social setting; the actor-network theory and ethnographic perspectives of figures such as Bruno Latour, Michael Callon and Steve Woolgar; and the interventions via feminism of figures such as Donna Haraway and Sandra Harding (Hess, 1997; Golinski, 1998). These, and numerous other strands of thought from figures such as Simon Schaffer, Michel Foucault and Joseph Rouse, have resulted in a tradition of research working with the notion of science as fundamentally local knowledge (see local knowledge).

Geographers have engaged with these developments in several ways. Thus some have turned to the proposals and methods of science studies to interrogate geographical knowledge itself. Barnes' scrutiny of economic geography and the quantitative revolution (Barnes, 1996, 2004b), Demeritt's (1996) reflections on social theory, science and geography, Thrift's (1996) interest in the social formations of knowledge, Whatmore's (2002a) elucidation of ‘hybrid natures’ and Amin and Cohendet's (2004) examination of the ‘architectures of knowledge’ in firms and economies are just a few investigations that are deeply informed, in one way or another, by these perspectives. At the same time, geographers have been in dialogue with practitioners of science studies in their enquiries into the part played by space, place and location in the production, consumption and circulation of scientific knowledge itself (Livingstone, 2003c). These latter currents in the spatiality of science stem from an interest in the role of venues such as the laboratory, the museum and the field in knowledge production; the significance of location in the reception of scientific knowledge; and the ways in which the universality of science has been accomplished through the management of various circulatory mechanisms.

Several critical statements by historians of science, such as Schaffer (2005), Ophir and Shapin (1991: see also Shapin, 1998), Kohler (2002) and Agar and Smith (1998), have firmly placed space on the science studies agenda, and this has been reinforced by the work of geographers on the geographies of scientific knowledge and on science as an inherently hermeneutic undertaking (Livingstone, 2002b: see also hermeneutics). The interface that has been developing is proving to be fertile. Geographers and others have thus been variously engaged in elucidating the ‘geographies of science’ in a range of ways and at a range of scales (see also geography, history of). An indicative sampling of this work would include examinations of the geographies of enlightenment and scientific revolution(s); the significance of museums, lecture halls and botanical gardens in the production and display of scientific knowledge (Naylor, 2002; Johnson, 2006); the practices of making science in the field (Withers, 2004; Lorimer and Spedding, 2005: see fieldwork); the geography of geographical knowledge itself in the constitution of national identity (Withers, 2001); the different ways in which the glacier theory was construed in different cognitive spaces (Finnegan, 2004); the role of spatial practices in fisheries science (Evenden, 2004); the social topography of
correspondence networks (Ogborn, 2002); the significance of field trials in the production of agricultural knowledge (Henke, 2000); the reciprocal connections between buildings and the building of scientific knowledge (Gieryn, 2002); and the geography of the commodification of bio-information (Parry 2004). The list could be extended ad libitum. Special issues of contributions by geographers to the British Journal for the History of Science (2005) under the guest editorship of Simon Naylor, and of Interdisciplinary Science Reviews (2006) on ‘putting science in its place’, bear witness to the interdisciplinary richness of these developments.

In the light of all this, there are good grounds for suggesting that science studies can coherently be thought of as a branch of HISTORICAL GEOGRAPHY. In keeping with this sentiment, Simon Schaffer (2005) has recently urged that it was the cartographic impulse itself that helped construct what we think of as modern science (see CARTOGRAPHIC REASON; CARTOGRAPHY). Courtesy of several ‘big picture’ accounts of science history (such as those of Whewell, Bernal and Needham) that sought to graphically chart scientific development, it was – as Schaffer (2005) pointedly observes – ‘maps which invented what science was’. At a more popular level, Simon Jenkins, writing in the Guardian (Friday, 20 January 2006), delivers confirmatory judgment, no less provocatively quipping that ‘All scientists are geographers. That is why maps are the most sacred tools of science.’

science park A particular form of GROWTH POLE established by property developers or, sometimes, research institutions to promote technology transfer and investment in new industries, usually in conjunction with a university and sometimes with regional and/or local government support. The goal is to capitalize on knowledge CLUSTERS in scientific and technological expertise by ensuring that INNOVATIONS are developed locally, generating jobs for the local or regional economy and contributing to the institution’s costs (see also KNOWLEDGE ECONOMY).

scientific instrumentation Scientific instruments are purpose-built material tools used by investigators to disclose, measure and represent aspects of the natural world. A subset of these devices devoted to SURVEYING has been used in CARTOGRAPHY, astronomy, navigation, land survey, geodesy and related geographical practices. Dating back at least to the activities of Vitruvius in the first century BCE, but particularly since the development of practical mathematics during the Renaissance, such instruments as the astrolabe, compass and theodolite were progressively refined until they were substantially replaced by the more recent use of signals from satellite systems, which deliver immediate calculations of exact locations (Bennett, 1987).

A useful distinction can be made between instrumentation for GEOGRAPHY and geographies of instrumentation. In the former case, scientific instruments have been used in the garnering of the GLOBE’s geographically distributed data and, routinely, to produce MAPS. Variations in terrestrial magnetism, for example, were the subject of much concern to Edmund Halley who, it was said, set about ‘the rectifying of geography’, by using his own instruments to determine longitude and produce charts of magnetic variation (Fara, 2005, p. 69). Similar matters occupied the attention of Alexander von Humboldt, who travelled through South America with a remarkable range of instruments – chronometers, sextants, dipping needles, a cyanometer (for measuring the blueness of the sky), barometers, thermometers, rain gauges, aeromotors, theodolites – and used the data they delivered to construct his famous ISOLINE maps, which were designed to facilitate the interdisciplinary transfer of data (Dettelbach, 1999; Godlew ska, 1999).

The fundamental role of instruments in the geographical project – and its colonial preoccupations – was enshrined, during the Victorian period, in the Royal Geographical Society, which began systematic courses on surveying in 1879 (Collier and Inkpen, 2003). Of course, these practices raised a range of EPISTEMOLOGICAL problems, rotating around who could be trusted to deliver reliable information (see TRUST), how distant observers were to be regulated and what were the appropriate instruments to use in distant places. In an attempt to address such problems, the Society published its Guide to travellers in many successive editions, in the hope of bringing discipline and order to distant observers, and thereby to secure testimonial credibility (Driver, 2001b).

This latter concern about how to manage the harvesting of global data for geography is intimately connected with the whole subject of
the geographies of instrumentation. The use of survey instruments and the regulation of observers in the production of geographical knowledge can be thought of as an inherently spatial strategy; it aims to conquer distance by bringing together widely distributed data and thereby integrating local knowledge into global networks. Just exactly what goes on as instrumental findings circulate from local site to global space constitutes a crucial set of questions in the geography of knowledge. During the ENLIGHTENMENT, ships’ captains collected magnetic measurements and returned them to the Royal Society. In the nineteenth century, atmospheric circulation data returned from hundreds of ships to the US Navy’s Depot Charts and Instruments were used by Matthew Fontaine Maury to construct his 1855 Physical geography of the sea (Burnett, 2005). At such key venues – centres of calculation, as Bruno Latour (1987) calls them – universality is constructed from particularity. But that conceptual circuitry is only achieved by industrious labour and careful management. The need to calibrate instruments, to normalize and careful management. The need to calibrate apparatus and normalized procedures that emerge from centralized nodes in the network are themselves, in turn, ‘assimilated and interpreted in each local context’ (Golinski, 1998, pp. 138–9). It is therefore noteworthy that historians of science have begun to speak of the ‘geography of precision’ (Schaffer, 2002), which identifies the inherently geographical nature of instrumental epistemology and the means by which ‘universal knowledge’ is made out of ‘local knowledges’ (see INDIGENOUS KNOWLEDGE). Further geographical scrutiny of the role of instrumental practice in the production of (geographical) knowledge is urgently needed.

scientific revolution(s) An abrupt cognitive transformation in a tradition of scientific enquiry that radically reinterprets existing data, identifies new problems and methodologies, and establishes fertile lines of novel enquiry. By thus emphasizing discontinuities in the history of SCIENCE, the idea of scientific revolutions runs counter to the standard cumulative understanding long championed by positivists and others who insisted that scientific progress comes about through the inductive accumulation of new data and the routine application of scientific method (see LOGICAL POSITIVISM; POSITIVISM). While the idea of scientific revolutions was put forward in the mid-nineteenth century by William Whewell, its most celebrated advocate was Thomas Kuhn, whose 1962 account, The structure of scientific revolutions, advanced a mechanism for understanding revolutionary science. To Kuhn, scientific fields embody paradigms – traditions with historical exemplars that express the standard theories, concepts and practices of a particular science. At certain points in time a new paradigm arises which is incompatible, and incommensurable, with its predecessor on account of the truly radical nature of the transformation. Kuhn’s model has been challenged from various quarters, and while he himself insisted that it was not applicable to the social sciences, it has nonetheless been applied in various ways to the evolution of HUMAN GEOGRAPHY and, most notably, by the architects of the QUANTITATIVE REVOLUTION that inaugurated SPATIAL SCIENCE (Mair, 1986; see also GEOGRAPHY, HISTORY OF).

But the term may also refer to a particular period in Western history, conventionally described as ‘The Scientific Revolution’, which has been widely regarded as of pivotal significance in the emergence of modern science. The expression was introduced in the 1930s to give unity to the period centring on the seventeenth and early eighteenth centuries, when figures such as Galileo, René Descartes, Johannes Kepler, Francis Bacon, Robert Boyle and Sir Isaac Newton transformed natural philosophy by their application of mathematical principles and experimental methods to understanding NATURE. favouring mechanical explanations, such figures championed first-hand observation of nature over the scholastic authority of figures such as Aristotle. This typification of ‘the scientific revolution’, however, has been challenged more recently by scholars stressing continuities with medieval metaphysics, diversities of outlook exhibited by key figures in the period and the continuing influence of a variety of magical perspectives on practitioners of the new natural philosophy. This has led some historians to query whether there ever really was such a thing as ‘the’ scientific revolution. As Shapin (1996, p. 1) audaciously put it in
the introduction to his revisionist account, ‘There was no such thing as the Scientific Revolution, and this is a book about it.’

Geographers and others working on this period have also come to stress the SPATIALITY of natural philosophy at the time, and the different ways in which what has come to be called The Scientific Revolution was constituted in different arenas (Livingstone and Withers, 2005). At the global scale of East and West, at the continental scale of European regionalism, and at the micro scale of dedicated scientific venues such as the LABORATORY and observatory, the new science was prosecuted in different ways. The influence of Chinese alchemy on medicine and the significance of Islamic geodetic methods on practical mathematics, the markedly different RHETORICAL spaces of the Italian court and the Royal Society, where scientific engagements were staged, the contrasts between knowledge-producing practices in the laboratory compared with the field, and differences across EUROPE in styles of patronage, pedagogic traditions, conduits of intellectual transmission and expressions of religious devotion all conspire to render troublesome the identification of something called ‘The Scientific Revolution’ as an essential singularity. Scientific revolutions have their own histories and their own geographies.

search behaviour The process of seeking out and evaluating alternative courses of action. In spatial DECISION-MAKING, searching – as in the selection of a new home – is often constrained by the FRICIONS OF DISTANCE, so that actors operate within spatially-delimited search spaces containing a subset only of all the options available to them.

secession The transfer of political control of a piece of TERRITORY from one polity to a new or existing polity. Commonly, the term relates to a REGION within an existing STATE aiming either to become part of another state or to function as an independent state. The process may be peaceful or manifest itself through TERRORISM and guerilla WAR. Contemporary examples include northern Italy (Giordano, 1999) and Chechnya. Increasingly, the process has been explored at the local level as LOCAL STATE units seek to secede from the authority of metropolitan units (Purcell, 2001).

Macedo and Buchanan (2003).

Second World A term that emerged during the COLD WAR to describe the communist, industrial states of the Warsaw Pact (formerly the Eastern bloc) in contrast to the countries of NATO. In time it came to refer to the centrally planned economies and communist party states of Central and Eastern Europe (e.g. Poland, Czechoslovakia, Hungary, Romania and Bulgaria), the Former Soviet Union states from the Baltics to the Black Sea (e.g. Belarus, Estonia, Lithuania, Latvia, Estonia, Moldova and the Ukraine), Russia, the Caucuses and the former soviet states of Central Asia (e.g. Kazakhstan), as well as China and other Maoist and Marxist states in the THIRD WORLD. With the widespread collapse of COMMUNISM since 1989, however, the term has fallen out of favour. Former ‘Second World’ states are now members of the European Union, experimenting with liberal political and economic systems, or pursuing market socialism (see POST-SOCIALISM; see also Pickles and Smith, 1998; Smith, 2005).

secondary data analysis In contrast to PRIMARY DATA ANALYSIS, this involves data collected by different researchers than those undertaking the analysis. The advantages are potentially a great deal of saving of time and resources, and thereby it is possible to extend the scope of a study well beyond the means of a lone researcher or even small teams. The disadvantage is that concepts may not be operationalized in the manner that the secondary analyst would ideally like. There are a number of sources of such data, which include data collected for primary research that has been subsequently made available to other researchers (see DATA ARCHIVE). It is increasingly a requirement of grant awarding that this is done. Another source is when a large-scale data collection is undertaken on behalf of the wider social science community. Important examples of these are the Panel Study of Income Dynamics, begun in 1968, a longitudinal study of a representative sample of US individuals and the family units in which they reside, and the British Household Panel Survey began in 1991 which is part of the European Community Household Panel. Geographers have been able to link NEIGHBOURHOOD data to the individual data from the panels without compromising confidentiality (Bolster, Burgess, Johnston, Jones, Propper
and Sarker, 2006). Researchers in the UK are also fortunate to have the birth cohort studies, which follow individuals from birth; the most recent Millennium Cohort has a clustered design so that local geographies can be researched (www.cls.ioe.ac.uk/mcs/). Another source is through record linkage of administrative data; this is likely to become of increasing importance as part of evidence-based policy whereby data are collected and disseminated on small local areas; a substantial and growing example of this is the Neighbourhood Statistics website (http://neighbourhood.statistics.gov.uk/) which has, for example, linked claimant count data to local areas to provide an annually updated measure of income poverty. The potential for such administrative data is immense but is challenging because all sorts of bias are likely to be present. An important recent development has been the use of a model-based approach to the use of records from different sources. Thus Jackson, Best and Richardson (2008) were able to use an overall multi-level model to combine detailed individual survey data from the Millennium Cohort Study with large-scale administrative data from the National births register, elaborating the model to handle a range of biases.

In Britain, the UK Data Archive (http://www.data-archive.ac.uk/) is the major repository of digital social science data; while in the USA, this role is filled by the Inter-University Consortium for Political and Social Research (http://www.icpsr.umich.edu/); globally such archives are organized into the International Federation of Data Organizations (http://www.ifdo.org/). All these websites have extensive search capabilities for identifying data archives organized into the International Federation of Data Organizations (http://www.ifdo.org/). All these websites have extensive search capabilities for identifying data being sought. King (1995) has gone further in his call that to ensure scientific integrity, replication data sets need to be made available that include all information necessary to reproduce empirical results; including software code for the particular analysis that has been undertaken. This is now being made manifest in the Virtual Data Centre (http://thedata.org/). Secondary analysis of qualitative data has been of less importance but its use is growing (Heaton, 1998).

sectoral model A model of residential patterns developed by Homer Hoyt (1895–1984: see Hoyt, 1939) for US cities, involving the segregation of housing of different quality and value into separate sectors radiating from the city centre along major routeways. Changes in the character of a residential area within a sector involved a filtering process whereby relatively affluent residents moved towards the urban fringe, thereby yielding their homes and neighbourhoods to lower-status in-migrants (cf. invasion and succession). The model – developed for mortgage-lending applications – was presented as an alternative to the Zonal Model and was later incorporated with it in a multiple nuclei model (see figure for that entry).

secularism An ideology in which religion and supernatural beliefs are not central to understanding the world, both religious beliefs and religious institutions should not interfere with the public affairs of a society, and are segregated from matters of governance. It is often associated with enlightenment in Europe, with its turn towards science and rationalism and its move away from religion and superstition. Secularism as a philosophy owes its origins to George Jacob Holyoake (1860), who introduced the idea that life should be lived by reference to ethical principles, and the world understood by processes of reasoning, rather than by reference to God or gods, or other supernatural concepts. From the perspective of government and governance, secularism refers to a policy that separates religious authority from the state. The opposite of secularism is usually theocracy; that is, where religion has a major role in government.

The secularist movement is split between those who believe that secularism leads logically to anti-religious propaganda and activism, and those who do not. Most modern ‘Western’ societies today are thought to be secular. Most would have near-complete freedom of religion. Religion does not officially
dictate political decisions, though it may influence the actions of individual politicians (but see Butler, 2008).

The divergent values of the secular state and religious groups have been a source of significant conflict. The prohibition of headscarves in schools in France is one example. At the same time, different secular states are secular to different extents and in different ways. Thus, while the secular state in France prohibits headscarves, in Canada, the secular state protects rights to wear religious markers in public schools.

Geographers have mostly been concerned about the intersections of sacred and secular in the landscape, or how sacred and secular ideologies impact on landscapes. Thus, in theory, a strictly secular ideology that underpins urban planning principles would not support the use of religious principles in the location of religious buildings, for example. However, in reality, different degrees of negotiations between sacred and secular ideologies prevail in most societies (Kong, 1993a, b).

security Freedom from imagined or real danger in the present or future. Geographical orderings of security are constructed through discourse and performance, and play an important role in constituting political and social geographies at a wide variety of scales. Discourses of security are always highly politicized and often vigorously contested. They involve the mobilization of imaginative geographies that swirl around notions of collective identity to invoke political threats, political change and political violence. As Dalby (2002, pp. 163–4) has suggested:

Security is about the future or fears about the future. It is about contemporary dangers but also thwarting potential future dangers. It is about control, certainty, and predictability in an uncertain world, and, in attempting to forestall chance and change, it is frequently a violent practice. [Security] is about maintaining certain collective identities, certain senses of who we are, of who we intend to remain, more than who we intend to become. Security provides narratives of danger as the stimulant to collective action but is much less useful in proposing desirable futures.

Geographies of international relations and the inter-state system are overwhelmingly constituted and re-made through realist discourses of national and international security. Through these, nation-states have traditionally sought to reify and naturalize their existence as ‘security containers’ using discourses of ‘national security’ that depict them as singular actors with incontrovertible national characteristics, homogenous populations and natural borders (Katzenstein, 1996). Such geopolitical discussions about national security tend to portray nation-states as facing existential threats from the incursions or ambitions of competing states and empires or – especially in the post-Cold War period – from non-state terrorist or insurgent groups. The Bush administration’s ‘global war on terror’, launched after the terrorist attacks on New York and Washington on 11 September 2001, is a dramatic example (Kirsch, 2003). Research within critical geopolitics (O’ Tuathail, 1996b), critical international relations and security studies (Campbell, 1998) has shown how nationalism, militarism and war are constructed and entangled through the invocation of such threats to ‘national security’. Imaginative geographies enlisted in the service of security typically represent the homeland as virtuous and righteous whilst simultaneously demonizing the space of the enemy. That space is increasingly seen as transnational and multi-dimensional: at once a ‘security region’ that requires monitoring and surveillance and, in the case of the USA, a unified combatant command pre-assigned to military intervention there (cf. Middle east; Morrissey, 2008b; 2009), and also a complex non-linear ‘battlespace’ (see military geography).

These conventional imaginations of national and international security have been sharply criticized for the way in which they legitimize military violence and neglect the environmental, social and biophysical underpinnings of the security of all human societies. In a post-Cold War world dominated by resource depletion, rapid population growth, intensifying urbanization and a series of deepening environmental and ecological crises, all of them compounded by highly uneven configurations of migration, capital investment and environmental risk, Dalby (2002) has called for conventional discourses of national security to be challenged by broader notions of what he terms environmental security. Addressing the ecological foundations of political, social and economic security, he urges that critical discussions about national security ‘need a more explicit engagement with the ecological conditions of contemporary urban existence’ (p. 184; see also biosecurity).
The United Nations Development Programme had already (1994) invoked the concept of 'human security' as a universally applicable notion that, crucially, shifts the referent of security studies from nation-states to peoples. This move focuses on the prevention and amelioration of a wide range of risks and hazards facing people in all human societies within what Beck calls a global risk society (Beck, 1998; see also Theranian, 1999).

These proposals are important, but they also collide with a recent stream of work on biopower, if they are understood to imply a transition from geopolitical regimes that take territory as their object to biopolitical regimes that take population as their object. Inspired by Michel Foucault's lectures in the late 1970s (translated as Foucault, 2007 [2004]), researchers are now asking urgent questions about the biophysical and medicalized vocabularies in which security is being re- visioned, and the ways in which governmental technologies of contingency are entering into the very construction of life itself (Dillon, 2008). In one sense, these more recent interventions reanimate and radicalize a stream of work on the ways in which hazards, risks and fear intersect in the constitution of everyday life. In major metropolitan centres in the global north and in the global south, the police have become increasingly militarized, and so has architecture – to such a degree, indeed, that there is now a critical online 'field guide to military urbanism' (Subtopia, at http://subtopia.blogspot.com: see also Caldeira, 1999; Low, 2004). The 'securitization' of everyday life has become so commonplace – so 'normal' – that one of the most popular, and certainly one of the edgiest, magazines on the role of technology in contemporary culture includes regular blogs on national security (Danger Room: http://blog.wired.com/defense) and on privacy, security, politics and crime (Threat Level: http://blog.wired.com/27bstroke6/). This brings us full circle, to a point at which strategic sites in cities are targeted by terrorist groups and these threats are used in turn to legitimate widespread efforts to securitize cities through installing checkpoints, defensive urban and landscape designs, and systems of intensified electronic surveillance (Graham, 2004a; Gray and Wyly, 2007; Katz, 2007).

**Segregation** The phenomenon of segregation is said to occur when two or more groups occupy different spaces within the same city, region or even state. The types of patterns identified as segregated go back to the beginnings of concentrated human settlement. Even ancient cities, for example, were usually divided internally into quarters associated with particular groups, and also characterized by a sharp separation between urban (inside the wall) and suburban (outside) groups. Human settlements have always been socially stratified and those designated as 'others' – whether based upon religion, culture, economic status or any other social division – have been relegated to specific, usually environmentally poor, places (see also other/otherness). That is, social marginalization is almost always associated with spatial segregation.

The degree of segregation, or separation between groups, varies. A group may be more prevalent in one area than another: for example, people of a particular religion may have a tendency to live near their place of worship but still live among people of other faiths, so that the degree of segregation is low. At the other end of the spectrum, groups may be pushed into separate areas and have their mobility curtailed, as in the Jewish ghettos created by the Nazis during the holocaust or the segregated districts imposed by the apartheid regime in South Africa. The process is not merely historical: at the end of 2006, for example, several local authorities in Italy decided to designate separate spaces for Roma (Gypsy) people, complete with fences and gates regulating movement in and out.

These examples highlight another crucial element: segregation can arise from discriminatory forces outside a group and/or from the social organization and predictions of the group itself. The internal side of this dynamic was first theorized by the Chicago School of urban sociologists, as they tried to understand the nature of immigrant settlement in early-twentieth-century cities in the USA. They believed that newcomers gravitated into enclaves specific to their cultural group and that these segregated areas helped people to come to terms with their new society. Gradually, as individuals adapted to American culture by learning English, upgrading their education and obtaining better jobs, they would move to multi-ethnic (non-segregated) neighbourhoods, typically in suburbs (see Suburbanization). Subsequent critics charged that the Chicago School
SEGRESSION

ignored powerful forces of RACIALIZATION involved in the creation and maintenance of enclaves generally, and that they particularly downplayed the RACISM that forced African-Americans into ghettos. A helpful intervention distinguished between SLUMS, neighbourhoods of POVERTY, and ghettos, places where racialized groups are trapped in poverty, which is transmitted intergenerationally (Philpott, 1979). Recent social geographers have been far more attentive to the ‘constraint’ side of segregation, perhaps to the detriment of understanding the degree of social organization within marginalized communities.

The consequences of urban ethnic segregation have been discussed at length by geographers and sociologists. In early statements by the Chicago School, enclaves were deemed beneficial as long as individuals only resided in them temporarily. Further, those who remained in enclaves were seen as insufficiently assimilated (see ASSIMILATION) and therefore at fault. Since then, assessments have been more complex, with several basic strands of thought. Some continue to see segregation as indicative of a reluctance to assimilate, and believe that enclaves and ghettos reproduce SOCIAL EXCLUSION because their inhabitants adopt a ‘culture of poverty’ associated with laziness, reliance on welfare, and crime (cf. Lewis, 1969a). Another, more critical, interpretation focuses on the institutional practices that perpetuate segregation and therefore the harm that it causes (Massey and Denton, 1993). From this point of view, segregated LANDSCAPES are both the result of inequality and also a mechanism for the reproduction of inequality. Other scholars have sought to reconcile the classic view of the Chicago School, that residents of segregated areas gain certain benefits, with these later critical perspectives, arguing that segregation can have both beneficial and deleterious effects (Peach, 1996; Logan, Alba and Zhang, 2002). Moreover, planned dispersion of marginalized residents of segregated neighbourhoods does not necessarily raise their level of opportunity or standard of living (Musterd, 2003).

The issue of segregation has become particularly charged in EUROPE, where prominent commentators have linked race riots in the UK and France to the effects of segregated urban environments (cf. Amin, 2003; Haddad and Balz, 2006). Those affiliated with the political right see concentrated minority/immigrant neighbourhoods as the result of a deliberate choice made by their inhabitants to embrace cultural isolation, an attempt to lead lives separate from mainstream society (for which the term ‘parallel lives’ is invoked: Amin, 2002a), while progressive critics believe that segregation is a response to racism and economic marginalization. Regardless, socio-spatial segregation is seen as an ingredient in social unrest.

The link between racialization and CLASS division, which is so obvious in the riots just discussed, is generally under-theorized in the literature on segregation. To a large degree, this omission reflects another legacy of the Chicago School. Over the past century, in geography at least, studies of segregation have been dominated by a concern for cultural forms of segregation rather than class. However, socio-spatial divisions based on class have been equally pervasive, and were first theorized in the mid-nineteenth century, as this famous statement by Friedrich Engels testifies:

Every great city has one or more slums, where the working-class is crowded together. . . . And the finest part of the arrangement is this, that the members of [the] money aristocracy can take the shortest road through the middle of all the labouring districts to their places of business, without ever seeing that they are in the midst of the grimy misery that lurks to the right and the left. (Engels, 1987 [1845], pp. 70, 86)

Arguably, the situation is exactly the opposite in contemporary cities: poverty is exposed, but affluence is hidden behind walls in GATED COMMUNITIES, protected by private security systems and electronic surveillance (le Goix, 2005). As in the past, the privileged protect themselves, though the mechanisms of this process, and the detailed spatial patterns that are generated, vary.

Recently, scholars have explored the relationship between different forms of segregation, such as socio-economic class and ethnic origin (Clark and Blue, 2004). Research has also shown the relationship between residential segregation and the educational system (Burgess, Wilson and Lupton, 2005; Denton, 1996), and the fact that CHILDREN raised in highly segregated neighbourhoods experience lasting difficulty as students, even when they are in universities outside their home city (Massey and Fischer, 2006).

SEGREGATION, MEASUREMENT OF

Social scientists have long tried to find ways of depicting and measuring the degree of segregation between groups in societies, especially cities. In early discussions of this topic, such as the classic studies by sociologists collectively known as the CHICAGO SCHOOL, segregation was portrayed in descriptive terms. Ernest Burgess (1967), for example, included maps that characterized areas of Chicago as the ‘Deutschland Ghetto’, ‘Little Sicily’ and the ‘Black Belt’. But these terms were highly generalized and none of the areas identified on the maps held completely mono-ethnic populations. Over the past century, sociologists and geographers have struggled to find more accurate ways to visualize and analyze segregation.

The social geography of a specific group is usually depicted in maps that are either based on standard percentage figures or as LOCATION QUOTIENTS (LQs). These maps show areas where a group is concentrated, providing a visual demonstration of the degree of segregation involved. A group that is fully integrated into the population at large would be evenly distributed across the territory in question (with all LQ figures close to 1.0), while a completely segregated (ghettoized) group would be concentrated in a single area, with low LQ figures throughout the map except in the area of concentration.

While maps such as these are undoubtedly an improvement over the impressionistic generalizations made in early sociological studies, they remain ambiguous. More precise statistics designed to represent the degree of segregation of groups were first introduced in the late 1940s and two gained ascendancy after a crucial paper published in the mid-1950s (Duncan and Duncan, 1955). The Index of Dissimilarity is a measure of the degree of residential isolation between two groups and is calculated as:

\[ ID_{xy} = \frac{1}{2} \sum_{i=1}^{k} |x_i - y_i|, \]

where \( ID \) is the Index of Dissimilarity between groups \( x \) and \( y \); \( x_i \) and \( y_i \) are the percentages of the two groups that reside in a particular spatial unit, such as a Census Tract, in a city (note that the difference in these percentages is taken as an absolute value and there are no negative numbers used in the calculation of the \( ID \)); and \( k \) is the number of spatial units that make up the whole. Arithmetically, the index shows the proportion of group \( x \) that would have to change its location in order to match the distribution of group \( y \). An \( ID \) value of 0 means the two groups are precisely co-located across the city or region in question, while a value of 100 would mean that the two do not overlap at all. The Index of Segregation (IS) is calculated in much the same way, but between an individual group and all other groups in a society; IS values also range from 0 to 100.

Although the \( ID \) and IS have been the most enduring measures of segregation, they share a number of problems. First, there is no straightforward way to decide when an \( ID \) or IS value is significant. After considerable debate, researchers have developed a consensus that values under 25 indicate little or no segregation, while those over 60 are interpreted as indicating a high level of segregation. Second, both indices are scale-dependent: they tend to be higher when a city or region is divided into a larger number of administrative units (Johnston, Forrest and Poulson, 2001). For this reason, comparisons of index values over time or between cities are suspect, unless the scale of spatial units is constant (which is relatively rare, particularly in international comparisons; see Van Valley and Roof, 1976). Third, index values for groups with small populations tend to be higher than those for groups that are large. Finally, indices speak to the degree of isolation of a group but do not describe particular spatial patterns. For example, the IS for a group that is entirely located in one inner-city neighbourhood, which is the only group in that place, would be 100. But the IS would also be 100 for a group located in four different suburbs if it was the only group in those areas. The reasons for these segregated patterns could be entirely different (the first group could be impoverished while the latter could be affluent), but the IS values would be the same.

A number of efforts have been made to provide better measures of segregation. These are summarized by Massey and Denton (1986), who discuss five dimensions of segregation (and measures associated with each). In addition to isolation or dissimilarity, they describe: concentration versus dispersion; centralization versus dispersion; clustering among groups (e.g. individual European-origin groups may be isolated from one-another, but all European-origin groups could be in the same general area of a city that is distinct from the location of Asians, Hispanics etc.); and the degree of exposure between groups (also see Lieberson, 1981). 
SELF-DETERMINATION

Despite the proliferation of indices, the ID and IS measures remain the most widely used, perhaps due to their ease of interpretation and mathematical simplicity. Also, these indices are adaptable to other types of study. For example, the same logic and formulae can be used to measure the degree of occupational segmentation, and in this case the IS would indicate the proportion of a group that would have to change occupations in order to have the same distribution in the LABOUR MARKET as the general population (e.g. Hiebert, 1999).

Massey and Denton (1986); Peach (1975).

**self-determination** The perceived right of a cultural group who identify with a particular piece of TERRITORY to control their political future. The concept falls within the broader political IDEOLOGY of NATIONALISM, but has a specific focus on the politics of overthrowing what is seen as unjust control of territory by an external power. Self-determination has been a rallying cry against IMPERIALISM and COLONIALISM, and is supported by the United Nations Charter. Indigenous groups, such as Native Americans and other ‘first peoples’, are contemporary advocates of self-determination politics, following the wave of DECOLONIZATION after the Second World War.

Macedo and Buchanan (2003).

**sense of place** This term is usually taken to refer to the attitudes and feelings that individuals and groups hold vis-a-vis the geographical areas in which they live. It further commonly suggests intimate, personal and emotional relationships between self and place. Thus, in early HUMANISTIC GEOGRAPHY, a ‘sense of place’ was understood largely in terms of positive affective qualities of place-attachment; that is, senses of affection, attachment and belonging and even ‘love of place’ (TOPOPHILIA: see Relph, 1976; Tuan, 1977). Such work belongs to a long-standing (and still influential; see Casey, 1998) PHENOMENOLOGICAL tradition in which place is presented as the meaningful, even potentially redemptive counter to abstract, rationalist and unlocalized notions of ‘space’. However, the more critical approaches characteristic of SOCIAL and CULTURAL GEOGRAPHIES from the 1980s onwards have more often sought to highlight how such positive senses of place and IDENTITY may in fact often be based upon the symbolic and physical exclusion of those deemed to be ‘out-of-place’ (Cresswell, 1996).

Equally, much early work on senses of place (e.g. Relph, 1976) subscribed at least implicitly to a particular historical narrative in which supposedly authentic or original forms of place-based COMMUNITY or dwelling are seen as being progressively eroded by economic and cultural forces such as URBANIZATION, INDUSTRIALIZATION and GLOBALIZATION. These forces are understood as working to occlude the distinctiveness of particular places and cultures, so producing an increasingly ‘placeless’ world. But in explicit contrast to such accounts, Doreen Massey’s (1994a) influential essay on a ‘global sense of place’ sought to advance a conception of PLACE as porous, outward-looking and progressive, as opposed to conservative, enclosed and unitary. The development of a progressive sense of place, for Massey, involves rejecting false nostalgia for pre-modern singular and coherent places, and embracing instead the culturally multiple, dynamic and connective aspects of place in a globalizing world.

While Massey’s work has opened up new agendas for geographical research on senses of place, older usages of the term, in which senses of attachment and belonging are foregrounded as investigative objects, continue to be productively elaborated and refined, most notably in Feld and Basso’s (1998) North American-based collection *Senses of place*. jwy

**sequence analysis** An EXPLORATORY DATA ANALYSIS technique for analysing LONGITUDINAL DATA. Social behaviours, such as housing careers defined in terms of tenure and price (Clark, Deurloo and Dieleman, 2003), are likely to be patterned with many sequences that are only trivially different across different households. Unlike other techniques, such as event history analysis, the aim is not to work spell by spell, trying to account for the transition from one state to another. In contrast, sequence analysis works holistically (Pollock, 2007), classifying ordered sequences into a relatively few characteristic trajectories and then seeking to examine what determines membership of a particular trajectory. Trajectories can be defined in both time and space, so that this approach can be used to identify common time-geographic paths (Shova and Isaacon, 2007).

676
A key part of the approach is that ordered sequences are clustered into a data-driven typology, according to some algorithm such as ‘optimal matching’ (Abbott and Tsay, 2000), which grew out of techniques developed during the 1980s and employed by biochemists to analyse DNA sequences. This works by measuring the dissimilarity of every pair of sequences by calculating the relative effort (the ‘cost’) needed to transform one sequence into another. Transformations are of three types – substitutions, insertions, deletions – and the user may attach a differential cost to each type of change so that, for example, moving from the rented sector to owner occupation may be given a higher cost than the opposite move. Dissimilarity is then defined as the minimum cost of transforming one sequence into another; the overall matrix of dissimilarities between all pairs can then be input to a cluster analysis, which groups together similar paths (cf. CLASSIFICATION AND REGIONALIZATION). The popularity of the approach can be expected to increase as more longitudinal data and general-purpose SOFTWARE FOR QUANTITATIVE ANALYSIS become available (Brzinsky-Fay and Luniak, 2006). kj

The publicly available software Transition Data Analysis has facilities to undertake sequence analysis (http://steinhaus.stat.ruhr-uni-bochum.de/tda.html).

sequent occupancy ‘The view of geography as a succession of stages of human occupancy . . . which establishes the genetics of each stage in terms of its predecessor’ (Whittlesey, 1929; cf. SETTLEMENT CONTINUITY). As this suggests, Whittlesey – like other European and North American geographers in the early twentieth century – was strongly influenced by biological MODELS. He acknowledged that the analogy between ‘sequent occupancy in CHOROLOGY’ and plant succession in botany would be ‘apparent to all’, but he insisted that his own conception of cultural–historical geography was more intricate. While ‘human occupancy of area, like other biotic phenomena, carries within itself the seeds of its own transformation,’ such uninterrupted or ‘normal’ progressions would be ‘rare, perhaps only ideal, because extraneous forces are likely to interfere with the normal course, altering either its direction, or rate, or both’ and ‘breaking or knotting the thread of sequent occupancy’. Whittlesey’s thesis directly resembles Frederick Jackson Turner’s FRONTIER THESIS: both men came from the American Midwest, and the transition from rural to urban societies was within living memory for them and their contemporaries. The idea was used more loosely by later cultural geographers to refer to little more than the claim that CULTURAL LANDSCAPES contain traces from the earlier stages of settlement (cf. Broek, 1932, which is usually regarded as the classic application). The biological METAPHOR was in decline in social science even as Whittlesey was writing, however, and in some ways the popularity of the thesis reflects the (then) isolation of HUMAN GEOGRAPHY among the social sciences in North America (Herbst, 1961).

GK

services Services have historically been defined as ‘activities which are relatively detached from material production and which as a consequence do not directly involve the processing of physical materials. The main differences between manufacturing and service products seems to be that the expertise provided by services relies much more directly on work-force skills, experience, and knowledge than on physical techniques embodied in machinery or processes’ (Marshall, Wood, Daniels et al. 1988, p. 11). Geographers have produced a substantial and still growing corpus of work on services, one by-product of which has been to confirm the difficulty of working with these sorts of general statements. It is clear that there is no single geography of services, and there are diminishing conceptual returns of thinking of services in this way. Rather, there is a whole set of different geographies of services, which vary according to the characteristics of the specific industry. The most recent definitional work has used binaries – either/or – to produce more specific definitions. So, terms such as PRODUCER SERVICES or consumer services, PUBLIC SERVICES or private services, and tradeable or non-tradeable services have been used. While these distinctions are an improvement on past generalizations, they pose their own problems. How to move beyond oppositional definitions? What is it that binds different services together or distinguishes them? For some, rather than seeing manufacturing and services as discrete, as separate entities, there is a need to conceptualize the COMMODITY CHAINS or production NETWORKS that link them (Henderson, Dicken, Hess, Coe and Yeung, 2001). If we trace these, then we generate a different set of insights into
SETTLEMENT CONTINUITY

the service component in ‘manufacturing’ and the manufacturing component in ‘services’.

The most recent work on the geographies of services has developed around four broad themes (Dicken, 2006). The first is the internationalization or globalization of service firms, with attention to why, how and to what extent they are becoming international in scope. In tandem with this emphasis on the dynamics of geographical expansion has come a widening in those industries in which geographers have performed empirical studies. We know now more about what is going on in those industries. The second theme is the intra-organizational dynamics of the service industries; in particular, on the strategies of small and medium-sized firms. In some parts of the world it is these types of companies, and not the largest transnational corporations, that are behind the growth of urban and regional economies. The third theme is the emergence of the knowledge economy: the rise of service activities as a function of the production and circulation of knowledge, and the growth of the knowledge industries – accountancies, business schools, consultancies of all types, law firms and so on – directed towards the construction of knowledge for economic gain. The fourth theme is performance and, specifically, the ways in which services are ‘performed’, reflecting the imprint of the cultural turn on economic geography (Thrift, 2005b).

These re-definitions and conceptual elaborations are vital because services have increased their absolute and relative importance in the economy (Bryson, Daniels and Warf, 2004). Service industries now contribute significantly to the economic performance of nations and cities and employ a growing number of workers. While geographers, and other social scientists, have been disputing how best to define services, others have been debating their economic importance, making political cases for and against particular forms of state intervention on the basis of projected economic impacts. This emphasis on service industries only reconfirms the importance of the work of geographers in this area of research.

settlement continuity The continuity of sites of settlement and systems of territorial organization across periods of social transformation, particularly associated with the arrival of new peoples and power structures into an area (cf. sequent occupancy). In historical geography, the term is most closely associated with a debate over the situation in Britain after the collapse of the Roman occupation and the establishment of the Anglo-Saxon kingdoms. At one extreme is the view that the sparse representation of British place names reflects an equally sparse Romano-British population that was rapidly overwhelmed by Anglo-Saxon immigrants who created their own distinctive landscapes. At the other is the view that the Anglo-Saxons were a small minority who rapidly acquired political control without diluting the ethnic identity of the British people. The latter is less well supported than the former, although evidence remains ambiguous for both sides of the debate. There are many instances of pre-English names adopted by the Anglo-Saxons and toponymic evidence suggests some kind of peaceful coexistence or cohabitation of British and Old English speakers (Cameron, 1980). The nature of the links to the Romano-British past clearly varied from region to region, but even in the Anglo-Saxon kingdom of Kent (a Roman name), founded by the middle of the fifth century, there is evidence of continuity in urban settlement and the estate structure in the countryside through a distinctive system of lathes (county subdivisions) centred on royal vill (townships) (Everitt, 1986). Similar systems are found over wide areas of northern England, suggesting that it was very old indeed. In much of the kingdom of Northumbria, the main units of authority extended over areas of c.100 square miles, centring on a royal vill to which all the inhabitants owed dues. Indeed, a system of this kind can be documented from later sources to have extended over a continuous belt from Wales across northern England into Scotland. It is possible that such forms of territorial organization reflect the impress of a Romano-British past that is also detectable in Kent (Jones, 1976). However, such views also have to confront the relative dearth of archaeological evidence for the Britons from the period after AD 400 in the southern and eastern areas of England. Nonetheless, there are few Anglian graves in the most northerly English regions, which certainly remained largely British. Furthermore, several Anglo-Saxon dynasties may have been partly British in origin (Wessex), suggesting that early Anglo-Saxon kingdoms were often older organizations that had come under invaders’ control, while the great majority of the
population stayed on to work the land (Campbell, 1982).

**settler society** A euphemism for brutal processes of racialized dispossession, along with the decimation or subjugation of local populations. Occupation through conquest has typically been justified in terms of doctrines of TERRA NULLIUS (empty lands), and assertions of progress and redemption. Indeed, the society that is salient in the term ‘settler society’ is precisely that which excludes racialized others. While this definition obviously encompasses huge swathes of the world, the term is most often associated with British colonial settlement (see COLONIALISM).

Celebratory versions of liberal historiography have long been dominant in the production of knowledge about settler societies. Challenging this stance, one influential strand of scholarship argues that such societies are best understood in terms of their incorporation within the capitalist mode of production (see CAPITALISM). Denoon, for example, recognizes ‘powerful strands of commonality’ (1983, p. 122) among the societies encompassed by his study – New Zealand, Australia and South Africa, as well as Argentina and Chile, from 1890 to 1914 – based on their integration into the international market and relations of dependency with imperial powers (see IMPERIALISM).

A subsequent body of critical scholarship insists on attention to articulations of GENDER, RACE, ETHNICITY and CLASS in the constitution and transformation of settler societies. Stasulis and Yuval-Davis (1995), for example, bring together studies that incorporate feminist and post-colonial perspectives (see FEMINIST GEOGRAPHIES and POST-COLONIALISM) in order to ‘unsettle settler societies’. Yet the range of ‘settler societies’ encompassed by the book – including the USA, Mexico, Peru, Algeria and Israel-Palestine, in addition to Australia, New Zealand, Canada, South Africa and Zimbabwe – raises the question of what is not (or has not been) a settler society. Indeed, the editors concede that their extremely broad conception of settler society underscores the difficulty of drawing a clear line of demarcation.

More recent work draws explicitly on critical conceptions of SPATIALITY. Where Stasulis and Yuval-Davis seek to unsettle, Sherene Razack’s (2002) edited collection aims at ‘unmapping white settler society’ – in this case, Canada. Focusing on the production of different racialized spaces, the volume is animated by ‘the fervent belief that white settler societies can transcend their bloody beginnings and contemporary inequalities by remembering and confronting the racial hierarchies that structure our lives’ (Razack, 2002, p. 5: see also WHITENESS). What is missing, however, is attention to the practices of counter-mapping through which native people in Canada have engaged in struggles for repossession.

Struggles for redress in situations of racialized dispossession are extremely widespread, and accelerating in some parts of the world, including Zimbabwe, South Africa and Aoteroa – New Zealand. They also underscore a crucial question regarding ‘settler societies’ – namely, whether and how the initial processes of settlement remain politically salient in the present. A key to grappling with this question is understanding historical geographies of racialized dispossession not as an event (or set of events) that can be consigned to some precapitalist or early colonial past, but as ongoing processes that remain actively constitutive of what Derek Gregory (2004b) calls the ‘colonial present’.

**sex** The term has been used historically to describe both sex differences – male/female – which are assumed to flow from anatomy, and a physical drive. Since the late 1970s both these meanings of sex, which characterize it as a biological given, have been problematized, and it has been re-theorized in increasingly complex ways. FEMINISM (Women and Geography Study Group, 1997) first introduced, and then troubled, the distinction between sex (biology) and GENDER (social meanings ascribed to biological differences). Foucault (1978 [1976]) identified sex and the related concept of sexuality as discursive constructions that are temporally and spatially specific.

**sexuality** In HUMAN GEOGRAPHY, there has been considerable interest in the mutual constitution of sexualities and space, so that most studies have focused on the SPATIALITY of the construction of sexual identities and the sexuality of SPACE. The earliest work on sexuality and geography focused on heterosexual prosthesis. In the 1990s a significant body of research developed, initially on the geographies
of lesbian and gay men, and latterly, on queer geographies (Bell and Valentine, 1995). This was facilitated by the development of post-modern thought within human geography that promoted a sensitivity to difference. As a result of the impact of this research, the study of sexuality and geography is often assumed to be synonymous with the study of lesbians, gay men and bisexual and transgendered people, yet there is a growing interest in geographies of heterosexualities, and sexuality is also important in geographical writing using psychoanalytic theory. The complex theoretical links between sexuality and gender, most notably in feminist theory, mean that the two are commonly discussed in tandem.

Work on geographies of sexualities has been most prolific within the sub-disciplinary areas of urban, social and cultural geography, but it is also gradually spilling out into other parts of the discipline, including economic geography, political geography and medical geography, in the form of research on the pink economy, sexual citizenship and HIV/AIDS, respectively (e.g. Bell and Binnie, 2000). The main strands of writing on sexuality and geography can be summarized as follows:

1. **Geographies of lesbian, gay and bisexual lives.** Lesbians and gay men lead distinct lifestyles – defined to a lesser or greater extent by their sexuality and others’ reactions to it – which have a variety of spatial expressions, creating distinct social and cultural landscapes in some contemporary cities. A number of studies have mapped gay commercial and residential districts. Knopp’s (1992) work on gentrification by gay men particularly contributed to analysing the role of sexuality within the spatial dynamics of capitalism. Studies of lesbian space have suggested that women also create spatially concentrated communities but that these have a quasi-underground character, although having a high level of visibility among lesbians themselves (Podmore, 2001).

   ‘Gay space’ – including gay commercial and residential districts (such as the Castro District in San Francisco) as well as lesbian, gay, bisexual and transgender (LGBT) parades, have been identified as important sites of political claims-making (Johnston, 2001). Yet the very success of these LGBT claims has led to the incorporation of these previously marginalized groups through the imaging, branding and commodification of gay space as a cosmopolitan spectacle for a heterosexual market (Bell and Binnie, 2004).

   While much of the work on geographies of lesbian and gay lives is located in the urban, there is an upsurge of interest in the structural limitations experienced by those living in rural areas, and the attempts of sexual dissidents to establish utopian rural communities.

2. **The heterosexuality of everyday space.** Studies have highlighted the fact that everyday spaces are commonly taken for granted as heterosexual, and have explored the processes through which spaces are produced in this way; and the disciplinary practices that regulate ‘public’ performance of sexualities (e.g. Valentine, 1993).

3. **Geographies of HIV/AIDS.** Mapping the transmission of the HIV virus has been at the heart of medical geographers’ attempts to trace its origins and establish global typologies. This work has been criticized by sexual dissidents as irrelevant and politically dangerous. Brown (1995) has played a key role in re-focusing geographical research on HIV/AIDS on to understanding sexual relations and issues of health and health-care promotion.

4. **Queer geographies.** These represent a reaction against the early work about the geographies of lesbians and gay men, which adopted an uncritical, all-embracing conceptualization of lesbian and gay identity. Drawing heavily on social theory from outside the discipline, queer geographies have attempted to scrutinize the desirability of identity politics and to challenge notions of fixed identities, in particular by employing the concept of performativity. Attempts have also been made to utilize the insights of queer theory to think about the production of space (Bell, Binnie, Cream and Valentine, 1994) and to explore the importance of mobility in queer quests for identity (Knopp, 2004). There is now an emerging body of work addressing queer identities from a post-colonial perspective – for example, focusing on queer diasporic community formation – and in the context of globalization and tourism (e.g. Hawley, 2001; Binnie, 2004). Here, geographers
have contributed to interdisciplinary debates about the ‘queer tourism’ industry and the differential positionings of racial, sexual, gendered and national subjects (Pu, 2002).

(5) Geographies of heterosexualities. These are most evident in historical and contemporary work on prostitution that has looked at the role of moral representations, social discourses and practices in regulating sex work (Hubbard, 1999). Geographical writing based on psychoanalytic theory has drawn on accounts of psychosexual development, sexual differences and desire, while also challenging the heterosexism evident in the writing of authors such as Lacan (see homophobia and heterosexism). There is growing interest in heterosexuality as an institution through which links between the body, the home and the public sphere are produced and negotiated (Little and Leyshon, 2003; Robinson, Hockey and Meah, 2004; see also heteronormativity).

(6) Critiques of the discipline. Geographers working on sexuality share many of the concerns of feminist geographers about the masculinist, heteronormative and disembodied heritage of the discipline, and about the operation of power within the academy.

shadow state A para-state apparatus comprising voluntary, non-profit organizations providing a host of goods and services. Although the form of the shadow state varies over time and between countries, it is commonly regulated and subsidized by public funds, simultaneously creating the ability to provide services while controlling political activism. Neo-liberal policies (see neo-liberalism) and decentralization of the state have increased the role of the shadow state in social service delivery and community development; provoking questions about the implication of unequal access to the shadow state for citizenship (Lake and Newman, 2002), governance and social justice (DeVerteul, Lee, and Wolch, 2002).

shift-share model A technique for describing the relative importance of different components of growth/decline in a regional economy, widely used in regional science. Growth may be due to a region having a high concentration of industries that are growing nationally, for example; because of locational shifts within certain industries towards that region; or because of differential regional trends within and across industries. Shift-share analysis splits a region’s growth (in employment, for example), relative to the national norm, into: (a) a proportionality shift, that proportion of the growth (decline) associated with the concentration of relatively fast(slow)-growing industrial sectors there; and (b) a differential shift, that proportion reflecting local trends that deviate from the national.

shifting cultivation Minimally, shifting cultivation is an agricultural system characterized by a rotation of fields rather than of crops, by discontinuous cropping in which periods of fallingow are typically longer than periods of cropping, and by the clearing of fields (usually called swiddens) through the use of slash-and-burn techniques. Known by a variety of terms (including field-forest rotation,
slash and burn, and swiddening), shifting cultivation is widespread throughout the humid tropics, but was also practiced in temperate Europe until the nineteenth century (and sometimes later) (Conklin, 1962). It is estimated that there are over 250 million shifting cultivators world-wide, with 100 million in South-East Asia alone. Shifting cultivation is enormously heterogeneous and subtypes can be distinguished according to crops raised, crop associations and successions, fallow lengths, climatic and soil conditions, field technologies, soil treatment and the mobility of settlement. Many distinguish between integral (shifting cultivation as an integral part of subsistence) and partial (shifting cultivation as a technological expedient for cash cropping; see peasant) forms of shifting cultivation (Conklin, 1962). In all shifting cultivation systems, the burning of cleared vegetation is critical to the release of nutrients, which ensures field productivity. Shifting cultivation by definition is land-extensive, and is threatened by population growth and migration, and expanding land occupation (see carrying capacity; intensive agriculture). Shifting cultivation is often stigmatized as primitive or unproductive, but it is typically predicated upon a sophisticated understanding of local environmental conditions – so-called indigenous knowledge – and exhibits considerable flexibility and adaptiveness.

**significance test**  A statistical procedure for identifying the probability that an observed event could have occurred by chance. Most statistics – such as a correlation coefficient – have an associated sampling distribution identifying all possible values of the coefficient for a given set of empirical observations. For example, three observations can be rank-ordered in six different ways, so that if one is correlating the rank-order of neighbourhood death rates with the local levels of lead pollution, there would be 36 different ways in which the two sets of three observations could be organized, each producing a different correlation coefficient. Those coefficients form a frequency distribution in which some values would appear quite frequently, others more rarely. If the observed coefficient’s value would occur only rarely, this outcome was unlikely to occur by chance: it is then presented as a significant result, as a correlation with interpretative value.

In studies involving large numbers of observations – 80 neighbourhoods instead of three, say – the frequency distribution can be predetermined and the observed statistic located within it. Most analysts operate the rule of thumb that if an observed outcome is likely to occur less frequently than five times in every 100 ways in which the data can be organized, that is a statistically significant result. Statistical significance should not be confused with substantive importance, however; it says nothing about the importance of findings and how they should be interpreted.

Statistical significance tests are used in two ways. In confirmatory data analysis, they assist hypothesis testing, indicating whether an observed outcome in a sample (see sampling) is likely to characterize the population from which it was drawn. (If the 80 neighbourhoods were a sample from 240 within a city, a correlation coefficient statistically significant at the 0.05 level would indicate that the relationship between the two variables in the sampled areas would almost certainly be found if the whole population had been studied.) In exploratory data analysis, there is no sample involved and the test is used to indicate the likely importance of an observed relationship occurring: one that would occur three times in every ten ways in which the data are organized is probably less important than one that would occur only once in every 500 ways. **MW**

**simulacrum**  A term originally derived from Platonic theory, but popularized by Jean Baudrillard. Literally, the simulacrum is a copy without an original. Baudrillard extended the argument about the modern dominance of images and ideology by suggesting an historical procession of the simulacra. First, there was presence – people met and spoke – then technology of writing allowed re-presentation of those who were not present. Now media allow the simulation of those who never existed. The term gained wide usage in discussions of themed environments such as Disneyland or shopping malls. ‘Main street’, Disneyland thus simulates a mythic idea of a small town community hub that has no counterpart in reality (see disneyfication). **MC**

**Suggested reading**

**simulation**  A heuristic device for solving otherwise intractable mathematical and
statistical problems. There are two broad types of application: the creation of ‘artificial worlds’, and the use of simulation as part of the estimation of quantitative models. An early application of the former was Torsten Hägerstrand’s work on the diffusion of innovation. He treated this as a spatial stochastic process, in that while it had an underlying structure (adoption would decrease with distance as social interaction decreases) it could also turn out differently each time. Monte Carlo procedures were used to draw random numbers and innovation diffused outwards from initial adopters according to a probabilistic mean information field. Such simulation has grown rapidly in recent years and it is at the core of micro-simulation methods and agent-based modelling. Such approaches have now developed to the extent of the SimBritain project, where as part of evidence-based policy the geographical impact of government policies can be evaluated (Ballas, Clarke, Dorling and Rossiter, 2007).

The second use of simulation, statistical model calibration, has also seen major recent developments, which have been considerably aided by increased computing power. One aspect of this is a computer-intensive approach to confirmatory data analysis and hypothesis testing, in which the observed data are re-sampled to characterize the empirical distribution of a test statistic. More importantly, a new method of estimation called markov chain Monte Carlo simulation has been developed that allows the estimation of very complex models, including multi-level models. This methodology allows a building block approach to estimation, so that complex problems can be decomposed into lots of small ones. It is especially important for Bayesian analysis, for it allows the estimation of previously intractable joint posterior distribution (based on prior beliefs, data and assumptions) by iterative simulation from the much more straightforward marginal distributions (Davies-Withers, 2002).

situated knowledge A term coined by the feminist cultural critic of science, Donna Haraway (1991, p. 188), to denote ‘a doctrine of embodied objectivity that accommodates paradoxical and critical feminist science projects’. Situated knowledge replaces the traditional conception of science as the pursuit of a disembodied, inviolable and neutral objectivity with a formulation of objectivity that stresses corporeality, social construction and cultural politics.

Haraway argues that vision or sight is a guiding metaphor for Western scientists in carrying out their work: they see the world, they make observations and collect evidence (from the Latin verb, videre, to see) and they write down its truths. This conceit carries over into ordinary speech too when we say, for example, ‘I see’, meaning ‘I understand’. The language of knowledge production is saturated with visual metaphors in both a technical-scientific and an everyday sense. But Wittgenstein reminds us that ‘the limits of my language are the limits of my world’, and in working within this language, in construing vision and visuality in this way, scientists limit their worlds by writing themselves out of their own stories: failing to recognize their constitutive role in world-making, they reduce themselves to the status of ‘modest witness’ (Haraway, 1997, ch. 1). That presumption of modesty, Haraway argues, is a direct consequence of the starting point of visuality. It creates the illusory possibility of a disembodied science. She calls this illusion a ‘god trick’, the idea that it is possible to have ‘vision from everywhere and nowhere’ (Haraway, 1991, p. 191). Moreover, it is just such a trick that is the basis of one of science’s most cherished ideas, objectivity, the belief in the possibility of a single, final, detached and unmarked ordering of the world. For Haraway (1991, p. 188), however, the ‘gaze from nowhere’, as she calls objectivity, is really a rhetorical move that hides and protects the interests of those who propose and benefit most from it, typically white Western men. ‘Modesty pays off . . . in the coin of epistemological and social power’ (Haraway 1997, p. 23: see also epistemology). In this sense, then, being a ‘modest witness’ turns out not to be very modest at all. It is a strategy to promulgate a particular kind of knowledge and to guarantee its unassailable truth, which is often indelibly marked by heteronormativity, masculinism and racism (as her case studies from the life sciences testify).

Haraway (1997, ch. 4) labels scientific practices that masquerade under the cloak of objectivity ‘fetishistic’ because such knowledge is represented as a thing rather than a social process. Fetishism would not occur if it were recognized from the outset that all knowledge is embodied and partial; that is,
‘situated’. And with that recognition comes the possibility of ‘a usable, but not an innocent doctrine of objectivity’ (Haraway, 1991c, p. 189). This form of ‘usable objectivity’ depends upon the two terms that underpin it:

(1) Embodiment means recognizing that knowledge is produced by specific bodies that always leave traces. Moreover, embodiment is not only human but also ‘machinic’. Machines see and record the world and, like humans, they are more than passive observers; they construct it on the basis of particular algorithms and assumptions (cf. Actor-Network Theory). For example, software used in the computer programs of Geographical Information Systems brings a systematic set of biases, hidden assumptions and aporias. Printouts and screenshots are not mirror copies of the world, ‘the view from nowhere’ but always the view from somewhere. Further, embodiment is collective not singular, mobile not fixed. Haraway (1991, p.195) writes: ‘feminist embodiment . . . is not about fixed location in a reified body . . . but about nodes in fields, inflections in orientations, and responsibil- ity for differences in material-semiotic fields of meaning’. Haraway’s objectivity is constantly in motion, tugged and pulled among the various nodes of its constitutive field.

(2) Partial knowledge implies a recognition that no one, except gods and goddesses, possess full (objective) knowledge. There are only partial perspectives, a consequence of our own circumscribed subject location that makes us who we are, and what we know. Haraway (1991, p.193) writes: ‘the knowing self is partial in all its guises, never finished, whole, simply there and original; it is always constructed and stitched together imperfectly.’

Embodiment and partiality are the conditions under which knowledge is acquired. Only when they are recognized as such is there hope of an attainable as opposed to a mythical objectivity. These are also the conditions of any politics. Embodied and partial knowledge necessitates that people literally reach out to one another and construct networks of affiliation: that is, they must engage in discussion, deliberation and evaluation; they thus come to recognize difference but also common beliefs and shared responsibilities. Through these ‘shared conversations in epistemology’, Haraway (1991, p. 191) argues, it is possible to forge ‘solidarity in politics’. This does not mean that the end result is unanimity, or even that networks and conversations set us on a collective trajectory towards some final agreement. To the contrary, that was the assumption (and the failure) of the old type of objectivity. Rather, ‘shared conversations’ are open-ended, varied, sometimes inconsistent and paradoxical. But they are all we have, and the necessary condition for both political projects, such as Feminism, and epistemological ones, such as science. As a result, the traditional notion of objectivity must be recast, conceived as an incomplete process, not a final outcome. Objectivity then becomes the process of working out difference and commonality, of struggling epistemologically and politically to make connections, affiliations, and alliances. While situated knowledge is often contradictory, it contains the possibility of critical promise.

It is in exactly this spirit that Gregory (1994) argues that visions of modern Geography as an intrinsically European science whose origins can be traced back to the late eighteenth century, and in particular to scientific expeditions beyond the shores of Europe (see Exploration), mask its genealogy as a distinctively Eurocentric science. Geographical knowledges, like any others, are always situated knowledges: their production often involves travel, like Cook’s voyages into the South Pacific or the orbits of Earth-sensing satellites through space, and the products themselves enter into complex circuits of exchange, transfer and accumulation, but they are always marked by the situations in which and through which they are constituted (see also Ethnocentrism; Eurocentrism; Orientalism). Merrifield (1995) treats quite other, more recent and more radical ‘expeditions’ as exercises in the production of situated knowledge, while Cook (2001a, 2004) has used Haraway’s proposals as a research method, a pedagogy, a form of writing and an exploration of Material Culture. In all these cases, however, it is important not to confuse situated knowledge with a form of Ideology-critique that subscribes to quite traditional notions of objectivity. For, as Rose (1997b) emphasizes, anyone claiming to fully situate their own knowledge is practising precisely the same kind of god trick that they criticize in others. All situated knowledge is partial, including the situated knowledge we have of ourselves and, of course, every entry in this Dictionary (cf. Local Knowledge).
effects (McDonough, 2002). Of materials to create new meanings and space 

The Situationist International (SI) was a group of revolutionaries based in Western Europe between 1957 and 1972, committed to transforming dominant social and spatial relations. Their critiques of capitalist as well as actually existing socialist states owed much to Marx as well as earlier avant-gardes such as Dada and surrealism. The group launched an uncompromising attack on the forces upholding what they believed were the alienating conditions of ‘the society of the spectacle’, characterized by the increasing colonization of social life by the commodity. They sought to encourage existing revolts against hierarchical power by theoretically and practically articulating forms of revolutionary contestation. At the same time, they experimented with means of criticizing and freely constructing daily life. Geography was central to this endeavour, as they understood cities in particular as both key sites in the reproduction of social relations of domination, and potential realms of freedom and possibility. The situationist Guy Debord thus argued that the ‘proletarian revolution is that critique of human geography whereby individuals and communities must construct places and events commensurate with the appropriation, no longer just of their labour, but of their total history’ (Debord, 1994 [1967], thesis 178).

The SI remained small, with a total membership of 70, from 16 different countries. Developing their positions through a range of texts and artistic, cultural and political activities, the situationists were highly critical of the orthodox Left, and referred to undermining rather than contributing to specialist arenas of art and academia. They therefore rejected the term ‘situationism’, claiming that it was a meaningless invention by opponents who were seeking to reduce their activities to a fixed dogma. The influence of the situationists has nevertheless been considerable and, after years of marginalization, has been increasingly recognized and reassessed. Interest has focused on their critique of the spectacle, and their associated critiques of urbanism and everyday life. Also influential have been practices of psychogeography as means of exploring and seeking ways to transform cities, and techniques of détourlement, involving the hijacking of materials to create new meanings and effects (McDonough, 2002).

Sjoberg model A model of social and spatial order of the pre-industrial city, first expressed in Gideon Sjoberg’s book of the same title (1960). Sjoberg’s model arises from his desire to provide a critique of, and alternative to, the concentric zonal model of the city offered by Ernest Burgess and, more generally, of human ecology as applied by prominent members of the Chicago School. As such, Sjoberg’s work was part of a larger project, initiated by Walter Firey (1947), to replace human ecology with structural functionalism as the central paradigm of urban sociology (p. 12). The major factors used to explain urban morphology in Sjoberg’s model are social structure and technology.

Sjoberg begins by differentiating between non-urban, feudal and industrial societies. He is concerned with the second of these: societies that utilize animate sources of energy, and are literate and urbanized, including all world civilizations prior to the industrial revolution as well as non-industrialized contemporary societies. He argues that feudal, or pre-industrial, societies everywhere, and through time, are characterized by similar technological achievements and a three-tiered class structure that includes a small ruling class, a large lower class and outcast groups. The ruling class, comprised of those in religious and administrative authority, establishes a social order that reproduces its control through the ‘construction of situations’ and the production of a ‘unitary urbanism’, which found its most vivid expression in projects by the Dutch artist Constant for a nomadic and ludic New Babylon, and in their later concern with political–theoretical critique in the name of realizing what was hidden yet possible in modern life. Returning to the SI’s utopianism and its critiques of urbanism, is not only of historical interest, it has been argued, but can also serve to challenge how urban spaces are imagined and constructed, and to encourage struggles for alternatives (Pinder, 2005c; see utopia). Resonances between situationist practices and contemporary political actions, especially over the production and contestation of space and in opposition to spectacular power, further demonstrate that, despite the ‘strange respectability’ that aspects of their project have recently accrued (Swyngedouw, 2002), they remain politically highly charged. DP
over succeeding generations: URBANIZATION is both the outcome of social stratification and a means whereby HEGEMONY is perpetuated. The MORPHOLOGY of pre-industrial cities reflects this interdependence between social and spatial order: POWER is consolidated by the ruling class through its residential location in the city centre, the most protected and most accessible district. Here, residents forge a social solidarity based on their literacy, access to the surplus (which is stored in the central area of the city), and shared upper-class CULTURE, which includes distinctive manners and patterns of speech. Elite clustering in the city centre is reinforced by the lack of rapid transportation.

The privileged central district is surrounded by haphazardly arranged NEIGHBOURHOODS housing the lower class. Households in these areas are sorted by occupation/income (merchants near the centre, followed by minor bureaucrats, artisans and, finally, the unskilled), ethnic origin and extended family networks. Merchants are generally not accorded elite status, since power is achieved through religious and military control, while trade is viewed with suspicion. The model is less clear on the residential placement of outcast groups (typically slaves and other conquered peoples): some of these perform service roles and are intermingled with the rest of the urban population, while others live at the extreme periphery of the city – frequently beyond its walls.

In formulating this model, Sjoberg reverses the logic used by Burgess – who placed commercial activities at the centre of the city, and a succession of poor through wealthy residential districts around it. Sjoberg notes that the Burgess model is applicable only to industrial cities, where production and commerce propel economic growth and where capitalists are accorded high social standing. Further, he argues that human ecology incorrectly treats urbanization as an independent social force, when in reality urban growth should be seen as a ‘dependent variable’, as it depends on the distribution of social power, and on available technology. Empirical investigations of the Sjoberg model have been generally supportive, but caution that the model cannot account for the intricate details of urban development across different cultural contexts. Others have criticized the theoretical content of Sjoberg’s work, especially his stress on the role of technology and his uncritical view of social power. Sjoberg’s functionalist logic (which blurs distinctions between causes and consequences), however, remains largely unnoticed and unchallenged (see FUNCTIONALISM).

skid row Essentially a North American term, ‘skid row’ traditionally referred to areas characterized by concentrations of roaming houses and accommodation for single men working in the timber industry: over time, the term has become a more general shorthand for areas where HOMELESSNESS is evident. Often offering hostel or temporary accommodation, skid rows are thus notorious as spaces of rough sleeping, with temporary pavement encampments or ‘cardboard cities’ offering refuge for those who congregate in these areas. In the larger skid rows, intricate SOCIAL NETWORKS and relationships may develop within the COMMUNITY, as well as between the service-dependent and those service providers who seek to assist them with welfare, alcohol, drug and HEALTH issues (Rowe and Wolch, 1990). In many instances, dwellers of areas described as skid row districts have fought to contest this designation: despite this, the term persists in the North American social imagination as a pejorative description of the social margins of the city.

Studies by urban sociologists and geographers have suggested that the development of skid row areas in North American cities has, in some cases, been connected to policies of containment designed to remove street homeless populations from wealthier locales. Yet currently the number of skid row districts is declining markedly, as corporate GENTRIFICATION of the central city squeezes homeless populations from sites that they have sometimes occupied for decades – see, for example, Smith (1996b) on the forcible removal of the homeless and itinerant population from Tompkins Square Park, New York. In such instances, anti-begging ordinances and zoning laws have been used to disperse visible homeless populations and ‘sanitize’ areas prior to GENTRIFICATION. Although the erasure of such ‘landscapes of despair’ should not be a cause for regret, it generates some significant questions about how welfare providers might best target resources to increasingly dispersed homeless populations (Lee and Price-Spratlen, 2004), as well as raising the spectre of the increased PRIVATIZATION of PUBLIC SPACE. As such, the disappearance of skid row areas is rarely taken as evidence of an
improving urban quality of life, but is seen to be symptomatic of societies where the disadvantaged have less ‘right to the city’ (Mitchell, 1997a).

**slavery** A condition of bondage and servitude in which one person owns another, forcibly exacts labour and services from them, and excludes them from CIVIL SOCIETY. Slavery has ancient roots in disparate parts of the world and has taken multiple forms. But up to the nineteenth century all EMPIRES were slave-owning societies, and slavery has been conceptualized by historians as a MODE OF PRODUCTION that both preceded and coexisted with FEUDALISM and with CAPITALISM. The close connections between slavery and COLONIALISM found their principal expression in the transatlantic slave trade, which reached its heyday during the seventeenth and eighteenth centuries, fed burgeoning European consumer markets with sugar, coffee, tobacco, rice and later cotton, and as Blackburn (1998) shows, was driven more by private capital and mercantile initiative than by state sponsorship. An estimated 11.8 million slaves – chiefly from West Africa – were put to work on plantations, and millions died of starvation and sickness in the perilous sea voyage to America. A considerable literature on PLANTATION life in Brazil, the Caribbean and the American South examines spatial strategies of POWER and RESISTANCE, modes of paternalism and HEGEMONY, and the role of GENDER, SEXUALITY and African CULTURE in the making of slave and Creole communities (see also TRANSCULTURATION).

The abolition of colonial – chattel – slavery stemmed from both metropolitan and colonial agitation, and cannot simply be explained in economic terms (e.g. in terms of the declining value of Caribbean sugar colonies). On the one hand, the British and French represented abolition as a distinctly Western triumph, and strong public sentiment created what David Brion Davis (cited in Lambert, 2005, p. 10) describes as ‘a profound change in the basic PARADIGM of social geography – a conceptual differentiation between . . . a “slave world” aberration and a “free world”’ norm’. But the formal demise of slavery also stemmed from slave rebellions and struggles over CITIZENSHIP and HUMAN RIGHTS that articulated ideas of RACE, NATION and EMPIRE in complex ways (Dubois, 2004). Such struggles had a much greater impact on ENLIGHTENMENT thought than has hitherto been recognized, and recent historical and geographical work on the mutual constitution of white and black IDENTITY, and the diasporic and transnational identities and communities shaped by slavery (a ‘Black Atlantic’ based on a shared history of commercial interaction and social degradation), demonstrates the need for more integrated and ‘networked’ (less rigidly hierarchical) understandings of the exactions and impositions bound up with this mode and phase of colonization and European commercial outreach.

The distinction between slavery and other forms of servitude has never been clear-cut, and in spite of the nineteenth-century abolition of colonial slavery, slavery-like practices have persisted, in systems of indentured labour, and state servitude in fascist Germany, communist China and the Soviet Union. The United Nations currently extends the definition of slavery to an array of widespread human rights abuses (forced labour, REFUGEE exploitation, PROSTITUTION, pornography, people trafficking and the use of children in armed conflict). Contemporary GLOBALIZATION, like the colonial and imperial globalizations that preceded it, depends on transnational flows of labour: for millions, however, the conditions of movement and the coercion of labour has transformed them into what Bales (2004) calls ‘disposable people’. The crucial axis here is not RACIALIZATION but, rather, GENDER and age: most of them, perhaps 80 per cent, are female and around 50 per cent are CHILDREN. Many of these victims have been induced into crossing BORDERS to escape POVERTY and find employment; in order to pay their traffickers, they are required to work to pay off their ‘debt’ (many never do) in return for elemental food and shelter. Trafficking and slavery cannot simply be folded into one another – the two are conceptually and legally distinct (Manzo, 2005) – but it is clear that slavery may well occur in the course of trafficking, and that both involve extreme forms of exploitation, usually by criminal gangs. Contemporary slavery cannot entail legal ownership, but VIOLENCE nonetheless establishes a regime of control, coercion and dependence that amounts to effective ownership. More than 40 per cent of the victims are forced into the sex trades (cf. Samarasinghe, 2005), while another 32 per cent are domestic servants or construction workers. In June 2006 the US government estimated that 600,000–800,000 people were subjected to such labour bondage each year. The major destinations are Europe, North America and the MIDDLE EAST. Many millions more endure bonded labour as a
means of paying off a debt or a loan in their own countries, especially in India, Pakistan, Bangladesh and Nepal. When these are included, the International Labour Organization estimates that the minimum total of people enduring some form of forced servitude is 12.3 million, while Bales (2004, p. 8) puts the figure at 27 million: both estimates are more than the total number caught up in the horrors of the Black Atlantic (Epstein, 2006).

slum An area of substandard housing and inadequate provision of public utilities (especially water and sanitation), inhabited by poor people in high densities, who develop a distinctive culture as a means of both survival and self-respect. The term originated in Britain in the early decades of the nineteenth century. Labourers living in the countryside endured wretched conditions too, but the overcrowding of tenements in the central districts of industrial cities – the shock cities of the age – and of capital cities such as London was symptomatic of the slump. Life in these communities became a central object of social commentary and investigation, in studies such as Engels’ *Condition of the English working class* (1844) and novels such as Dickens’ *Hard times* (1854). Areas of poor housing for poor people had existed in many other periods and places too, from imperial Rome to Georgian Bath, but it was the connection forged between the built environment and the ‘moral environment’ – by the close of the century, fears over public order and public health were increasingly compounded by biopolitical theses of ‘urban degeneration’ (cf. Luckin, 2006) – that was diagnostic of the politics of the slump on both sides of the Atlantic. The connection was both constructed and contested (Ward, 1976), so that slums were not only the product of intersections between housing and (often casual) labour markets but also of a particular imaginative geography (Stedman Jones, 1991 [1974]; Mayne, 1993). Their modern analysis has relied on recovering built forms and material cultures, and analysing contemporary photographs and memoirs (Rose, 1997a; Mayne and Murray, 2001; cf. Roberts, 1990). Slums became targets for state intervention, including social regulation and urban renewal in the nineteenth century – one of the objectives of the Haussmannization of Paris – and ‘slum clearance’ schemes in the nineteenth and twentieth centuries (Wohl, 1977; Yelling, 1986, 2000).

The political salience of the term has been revived by critics such as Davis (2006), who points to the contemporary transposition of slums from the global North to the global South. Colonial cities were often bipolar, with a *cordon sanitaire* between the European districts (the ‘white city’) and the poor, overcrowded ‘native city’, but the slump is primarily a product of class zonation rather than the racial discriminations associated with the ghetto. Class distinctions loom large in the rapidly growing cities of the South, and it is estimated that one-third of the global urban population now lives in slums, the vast majority of them in the South (Davis, 2006, p. 23). If the overcrowding, poverty, human degradation and exploitation are familiar from older descriptions – ‘There is nothing in the catalogue of Victorian misery that doesn’t exist somewhere in a Third World City today’ (Davis, 2006, p. 186) – the immensity of scale is radically new. And unlike the nineteenth-century slums of the North, most of these new slums are on the edges of cities (not at the core) and their production is wired to transnational (not national) circuits of capital and to the political–economic projects of neo-liberalism. Finally, if slums have always been sites for the warehousing of what Marx called a ‘surplus army’ of labour, the new slums confront real armies who foresee urban warfare swirling around our ‘planet of slums’ (Davis, 2006, pp. 202–6). Although this dystopian vision is rhetorically powerful, however, it offers a remarkably undifferentiated view of a far more complex urban geography and it overlooks the crucial contribution of progressive urban social movements (Angotti, 2006). Indeed, Roy’s (2003) incisive exposure of the politics of poverty in Calcutta is explicitly staged as ‘a satire on the very trope of the dying city’ and, like Simone’s (2004) brilliant study of four African cities, is a critique of the urban fantasies (and fears) of abjection and failure projected on to cities of the global South by planners and theorists alike, and contained within the very concept of a ‘slum’. (See also squattting.)

social area analysis A theory and related technique for characterizing urban residential neighbourhoods, linking changes in urban social structure to economic development.
and associated URBANIZATION (termed a society’s ‘increasing scale’: Shevky and Bell, 1955). Increasing scale (not to be confused with other uses of that term – see SCALE) involves three interrelated trends:

- Changes in the range and intensity of social relations produced by greater DIVISION OF LABOUR and reflected in the distribution of skills and rewards within society – this trend was termed social rank or economic status.
- Increasing differentiation of functions within society and its constituent HOUSEHOLDs generating new lifestyles and household forms – termed urbanization or family status.
- The concentration into cities of people from different cultural backgrounds – segregation or ethnic status.

The link between these three trends and residential differentiation was not clear in the original presentation. Shevky and Bell selected variables to represent the three trends (the percentage in certain occupations for economic status, for example), which were measured for the various CENSUS TRACTS in a city and used to produce standardized indices for each tract on each construct. The tracts were then classified into a typology of social areas depending on their values on the three indices.

Although the technique was soon superseded by the more inductive approach of FACTORIAL ECOLOGY, and the theory was largely ignored within URBAN GEOGRAPHY, the three constructs remained central to much analysis of urban residential patterns.

SOCIAL CAPITAL

social capital The idea that access to and participation in groups can benefit individuals and communities – the nub of contemporary social capital scholarship – is a well-established sociological insight dating to the nineteenth century writings of Karl Marx, Emile Durkheim and Ferdinand Tonnies, among others. The term itself was first invoked (and then only once) by the economist Glen Loury in a 1977 article in which he critiqued NEO-CLASSICAL theories of racial income inequality. Loury contended that by its commitment to methodological individualism, orthodox labour economics was incapable of factoring how social context – specifically, poorer connections of young black workers to the labour market and their lack of information about opportunities – impeded intergenerational mobility and reproduced race divisions rooted in economic inequality (Loury, 1977).

The sociologist Alejandro Portes (1998) attributes the first theoretically refined analysis of social capital to Pierre Bourdieu, who defined the concept as ‘the aggregate of the actual or potential resources which are linked to possession of a durable network of more or less institutionalized relationships of mutual acquaintance or recognition’ (Bourdieu, 1985, p. 248). Although Bourdieu’s note, initially published in French in 1980, remained neglected within the English-speaking world, the concept of social capital proliferated, catalysed by a conjuncture of events. These included the publication of an article in the late 1980s by a leading American sociologist, James Coleman, in which he explored the connection between aspects of ‘social structure’ and ‘human capital’ formation (Coleman, 1988). Although Coleman’s treatment of social capital lacked the rigour of Bourdieu’s formulation, it garnered far more traction. Post-1989 MARKET triumphalism, accompanying receptivity within and outside academia (e.g. at powerful multinational institutions such as the World Bank) to non-dirigiste sources of economic DEVELOPMENT, and the linked emergence of a ‘global CIVIL SOCIETY’ discourse (which conflated ideas of free society and free market) undoubtedly contributed to the popularity of Coleman’s thesis.

Since then, mainstream social science has operationalized the concept of social capital in a bewildering number of ways. The shared impulse has been to parlay CULTURE in a form sensible to economics and policy science. This importation of culture into the economic is sorely inadequate (see CULTURAL ECONOMY). Of the three broad categories of empirical approaches currently in vogue, the first evaluates how social relations might function as collateral or assurance that an economic transaction will occur in the manner anticipated – the distilled wisdom here is that social capital in the form of trust minimizes the risks (and, hence, costs) associated with transactions and boosts economic competitiveness. A second approach measures how social capital as density of strong and weak social ties and group membership acts as an insurance mechanism during periods of need or crisis – the contention being that social cohesion is positively correlated with the ability of individuals to shield themselves from idiosyncratic risks. A third approach conceptualizes social capital as a
stock of accumulated obligations that can yield economic returns to the individual holder, either on an everyday basis or as investment in social relations with expected returns in the marketplace – hence, rendering the cultural into a form that is fungible with the economic.

While Bourdieu also emphasizes the fungibility of different forms of capital (academic, cultural, social, symbolic) and the reduction of all forms ultimately to economic capital, defined as accumulated human labour, his writing also reveals that ‘social capital’ – relations of abstract trust and reciprocity (displaying qualities of a quasi-public good) that inhere in society and facilitate economic transactions – as a social resource is: (a) a positive externality generated by a large number of individuals able to pursue conduct that they believe, given their semiotic universe, will earn them social distinction; (b) an unintended normative outcome that congeals through a long history of repeated interaction, rather than something that can be purposively manufactured in a relatively short time span (as some policy-oriented social theorists and their institutional backers are prone to claim); and (c) always anchored to a place and a community, and as such, containing the potentially coercive elements of social surveillance and pressure to conform, backed by the threats of social exclusion and excommunication (Gidwani, 2002).

social construction The idea that the social context of individuals and groups constructs the reality that they know, rather than an independent material world. Knowledge is always relative to the social setting of the inquirers (cf. relativism), the outcome of an ongoing, dynamic process of fabrication (anti-realism). Further, social construction applies as much to forms of specialized understanding (e.g. high-energy physics) as it does to everyday, taken-for-granted knowledge.

Antecedents of social constructionism are found in Plato, but it was Karl Marx (1818–83) who established an intellectual agenda with his claim that the interests of the dominant social class (the bourgeoisie) shaped individual beliefs (see ideology). Marx (1904, preface) wrote: ‘It is not the consciousness of men [sic] that determines their social being, but, on the contrary, their social being that determines their consciousness.’ Antonio Gramsci’s (1891–1937) theory of hegemony developed Marx’s idea by arguing that even seemingly humdrum commonsense thinking was socially produced and, because they could not think otherwise, resulted in the working class consenting to their own domination. But the most direct statement of social construction was provided in 1966 by two American sociologists, Peter Berger and Thomas Luckman. This was significant in two ways. First, it provided a simple and remarkably popular sketch of what they called ‘the social construction of reality’ (there were more complicated versions: Luckmann was keenly interested in Alfred Schütz’s constitutive phenomenology and the production of the lifeworld). Second, it located social construction within the sociology of knowledge. ‘Insofar as all human “knowledge” is developed, transmitted and maintained in social situations,’ Berger and Luckman (1966, p. 3) wrote, ‘the sociology of knowledge is concerned with the analysis of the social construction of reality’.

Using the example of religion, Berger and Luckman argued that social interaction, bolstered by associated institutions such as the church, constructs knowledge, taking on causal powers and entering everyday life routines. This insight was later applied by science studies to the physical world, nature, rocks and quarks (Pickering, 1984). On the surface, nature appears fixed and constant, to be ‘out there’, and not dependent upon social beliefs. But science studies contend that scientific knowledge is no different from any other kind of knowledge. Social context operates by shaping the scientific techniques, equipment and forms of reasoning used by scientists to erect particular constructions of nature (and linking with situated knowledge that also emphasizes the world-making constructions of scientists and their technology). That scientific knowledge is socially constructed does not make it wrong, however. What is wrong is belief in a science that escapes the influence of its social setting. Rocks and quarks do not express themselves in their own terms, but only in the terms of the scientists who speak for them, and thus the social worlds that those scientists inhabit.

Social construction has had a diffuse but, in some respects, a widespread influence in human geography. The first engagements with Berger and Luckmann’s theses remained close to their origins in sociology and were confined to their implications for social geography, particularly by those sailing under
the flag of a humanistic geography and interested in phenomenology, symbolic interactionism and the constitution of meanings in the conduct of everyday life. The influence of the sociology of scientific knowledge came to the discipline much later, by which time it was typically associated with postmodernism and post-structuralism. The latter in particular introduced the concepts of discourse and performativity, which directed attention to the constitutive, ‘world-making’ effects of the nexus of power, knowledge and practice. In this spirit, human geographers have explored constructions of the economy (Barnes, 2005), gender (Pratt, 2004), nature (Castree and Braun, 2001) and sexuality (Brown, 2000), to name but a few.

Hacking (1999).

Social exclusion
A situation in which certain members of a society are separated from much that comprises the normal ‘round’ of living and working within that society. The concept is chiefly envisaged in social terms, identifying particular groupings that become excluded, but it is also recognized that the multiple factors involved in creating social exclusion may combine spatially to produce distinctive places of disadvantage and discrimination (Gough, Eisenschitz and McCulloch, 2005). Indeed, excluded groupings tend to be found outside those spaces comprising the loci of ‘mainstream’ social life (e.g. middle-class suburbs, up-market shopping malls, prime public space), congregating elsewhere as the residents of spaces largely hidden from the view of academics, politicians and policy-makers (e.g. working-class estates, homeless shelters, anonymous back streets).

The term ‘social exclusion’ has been popularized in policy-making across Europe, if less so North America, and has particularly featured in the social policies of recent UK governments. The definition favoured in the UK is broadly thus: ‘the outcome of processes and/or factors which bar access to participation in civil society’ (Eisenstadt and Witcher, 1998, p. 6). As a concept, social exclusion ‘does not simply describe the static condition of “poverty” or “deprivation”, but emphasises the processes by which aspects of social marginalisation are intensified over time’ (Amin, Cameron and Hudson, 2002, p. 17), and it also embraces a diversity of economic, political, social and cultural dimensions. While some are sceptical, others see social exclusion as an advance over notions such as the ‘underclass’, originating in the USA, that effectively blame people for irresponsible lifestyles bringing their marginalized status upon themselves.

‘[T]he debate on the causes and locations of social exclusion, as well as proposed solutions, has become cast in terms of geographically-defined communities’, but there are snares in this ‘new hegemony of the social as local’ arising from a neglect of broader structural forces, whose malign impact on neighbourhoods is unlikely to be reversed by local initiatives alone (Amin, Cameron and Hudson, 2002, pp. 19–22). Many considerations ripe for critical analysis emerge, including the articulations of social exclusion with the ‘social economy’ of not-for-profit activity and also the possible deployment of social capital, all of which can be traced across what Gough, Eisenschitz and McCulloch (2005) term ‘spaces of social exclusion’ inescapably skewed by the workings of both the local and the global. Relatedly, attention is drawn to the policies of social inclusion, designed to counter exclusionary tendencies, and new forms of citizenship, marked by the privileging of ‘active citizens’ supposedly able to take responsibility for their own well-being, circumstances and neighbourhoods.

An academic geographical concern for socio-spatial exclusion pre-dates the current policy interest, though, and can be traced in a manner explicitly framed as such to Sibley’s (1981) innovative Outsiders in urban societies. Through substantive studies of ‘Gypsies’, travellers and the North American Inuit, Sibley anticipated a new tradition of research into excluded minority groupings that has now greatly extended the compass of social geography. All manner of peoples standing outside of the mainstream, on whatever grounds, have now had their ‘exclusionary geographies’ mapped, interpreted and critiqued, with sensitivity shown to both structuring forces from without and felt experiences from within. It is possible to identify works in this vein tackling women, people of colour, refugees, sexual ‘dissidents’, children and elderly people, disabled and chronically ill people, welfare-dependent and homeless people, and many others (for accessible introductions, see Pain, Burke, Fuller and Gough, 2001; Panelli, 2004). These are people who are excluded because of who they are, how they look, and what they do and think, and who are therefore deemed ‘out of place’ (see also Cresswell, 1996) in a range of mainstream spaces that
they either choose to vacate (to avoid hostility) or because they are compelled to do so (by stigmatizing acts both symbolic and real). Various studies conceptualize the roots of such socio-spatial exclusion, notably Sibley’s (1995) Geographies of exclusion, which borrows from psychoanalytic theory to probe the inherent will of ‘the Self’ to distance itself from all that it perceives as ‘Other’ (as alien, impure, polluting and ‘abject’). Sibley speculatesthat such psycho-dynamics, as inculcated in individual psyches, translate into wider socio-spatial configurations that materialize lines of exclusion between selves who reckon themselves to be essentially similar (the ‘same’) and those cast out as fundamentally ‘Other’. CP

social formation In structural marxism, the specific combination of social relations obtaining within a particular society at a particular historical moment or conjuncture. The concept was derived from a reading of Marx’s Capital undertaken in the 1960s and early 1970s by a group of French scholars associated with the Marxist philosopher Louis Althusser. Whereas the mode of production specifies structural combinations of relations and forces of production in general terms, identifying the diagnostic class relationships involved in the production of surplus value – hence, for example, feudalism or capitalism – the concept of ‘social formation’ refers to concrete forms of social relations at a specific conjuncture (e.g. post-revolutionary France). It also takes account of social relations and forms that survive from previous conjunctures, as well as non-class modes of social exploitation and oppression (e.g. patriarchy), and seeks to identify their modes of articulation with what is assumed to be the central grid of class relations.

social geography The sub-discipline that examines the social contexts, social processes and group relations that shape space, place, nature and landscape. The generality of this definition indicates both the breadth of social geography and changing emphases through time, across various paradigms and also in different national traditions. In France, for example, social geography has sometimes been regarded as having the range of human geography itself, while in Germany it was often associated more narrowly with the landscape indicators school (see the continuing series since 2003 on national social and cultural geographies in the journal Social and Cultural Geography). Three abiding theoretical concerns in the sub-discipline have been the relationship between spatial pattern and social process; the question of determinism and human agency; and the engagement with a range of geographical scales.

Following the practice of human geography itself, early work in social geography was dominated by an emphasis on landscape form and spatial pattern. Innovative voices urging that intellectual labour should move beyond descriptive pattern studies to explanatory process included Wreford Watson’s seminal chapter (1957), Max Sorre’s (1957) productive engagement with French sociology, and Emrys Jones’ impressive monograph (1960) on the development of social areas in Belfast. Ironically, the new paradigm of spatial analysis in the 1960s did not significantly advance the explanatory ambitions of social geography but, rather, reinforced the emphasis on pattern by borrowing from human ecology to establish more rigorous quantitative descriptions of segregation patterns and classifications of social areas. While often sophisticated, only rarely did this work move into issues of explanation – as, for example, in Peach’s (1996) important research on ethnicity and immigration, as he considered economic and discriminatory explanations of segregation and, in earlier work, the restricted social interaction that was associated with maps of social segregation.

Akin to geomorphology’s transition from form to process, social geography moved decisively into process studies in the 1970s with two significant developments. The first was David Harvey’s (1973) paradigm-shaking discovery of Marxist theory (see marxist geography), leading to his claim that capitalism was the root cause of social–spatial distributions, and the two-class system was the fundamental expression of social groups, a research programme that has helped to shape a continuing and vital critical tradition in social geography (e.g. Blunt and Wills, 2000). In contrast to such a political economy, the second development was a humanism that emphasized the experience and construction of place, seeking inspiration from a range of theoretical and philosophical sources (Jackson and Smith, 1984; see humanistic geography). Humanism was not incompatible with some forms of Marxism, as work in historical geography made clear, but contemporary humanistic approaches
were much more attentive to issues of experience, identity and human agency in place-making (Buttimer and Seamon, 1980). They also continued earlier resistance to environmental determinism, though by the 1970s the economic environment had replaced the physical environment as the privileged context of human action. By the 1990s, social constructionism (see Social construction) had become a dominant position, and several important monographs used it to good effect (e.g. Anderson, 1991b), though sometimes risking a newer social determinism.

Humanistic and qualitative research were much more attuned to ethnographic and micro-scale studies, and attempts were made to effect a theoretical convergence between agency and structure and the micro- and macro-scale, notably in the short-lived structuration perspective. While that scaffolding has largely fallen away, the best work today continues to attempt to marry agency and structure, and micro- and macro-scale processes (e.g. Duncan and Duncan, 2004b; Mitchell, 2004a).

A number of authors have associated the explosive growth of social geography following the social movements of the 1965–75 period with the newly awakened desire for relevance in human geography. Aside from the theoretical issues noted above, what was at stake was also a liberal impulse towards social welfare and, for some, social activism. A wide range of research topics came under scrutiny, beneath the initial rubric of geographies of social problems (Herbert and Smith, 1989). Some of these, including the geography of crime and policing (e.g. Herbert, 1997), and especially health geography (Gatrell, 2002), are becoming sub-disciplines in their own right. Other significant research topics include poverty and deprivation, social polarization and social exclusion, education, housing and, in the consumer age of neoliberalism, geographies of leisure, tourism, sport and consumption. In David Smith’s work, a challenging progression has taken place from a consideration of welfare and social justice to a more philosophical, but still activist, examination of moral geographies and an ethic of care (Smith, 2000a).

The stratification of society in contemporary social geography follows topical as well as theoretical categories. Class, variously defined, remains a major line of demarcation, but it is far from alone. Race and ethnicity have been a significant focus of attention, particularly with the growing cultural diversity in gateway cities in the global north accompanying migration and refugee streams from the global south. Geographers have completed research on such topics as segregation and integration, immigrant reception and racism, transnationalism and multiculturalism as a governance policy (e.g. Anderson, 1991b; Peach, 1996a). Feminist geographers have affected the field as a whole (Pratt, 2004), engaging structures of patriarchy and diverse expressions of gender and sexuality, among other topics. But class, race and gender are not the only divisions recognized in society by social geographers. The life-cycle offers its own distinctive groupings, with studies of childhood, youth and the elderly, as well as varied family configurations (e.g. Aitken, 2001: see also ageing; children). Among cultural attributes, both religious status and aboriginal status are experiencing revived emphasis as sources of group formation (see aboriginality; religion). Disability studies have attracted a small but active scholarship on the spatial experience of differently abled groups (Park, Radford and Vickers, 1998). In short, the range of the social is substantial, and the postmodern attention to multiple and centred identities in cities of difference ensures continuing multiplication of the social groups of interest to social geographers (Fincher and Jacobs, 1998). Institutions, too, are social formations with particular rules, hierarchies and cultures, and the return of institutional approaches in the social sciences (see institutionalism) has encouraged more systematic study of the involvement of public and private corporations in shaping people and place (e.g. Herbert, 1997; Ley, 2003b), reinvigorating the managerial or gatekeeper approach to place-making of the 1970s.

Social geography experienced a second period of expansion in the 1990s, benefiting from the renewal and expansion of cultural geography. Indeed, the boundaries of the two sub-disciplines are blurred, and strict demarcation neither possible nor necessary. Today, social geography ranges widely – indeed, some might say, too widely. Like geomorphology, the preoccupation with process has sometimes led some distance from recognizable geographies of space, place, landscape or nature. Another trend has been the remarkable diffusion of qualitative methods as the primary and often exclusive methodology of social geography. There would seem to be advantages to more methodological diversity to make use of large national surveys and databases that require modest quantitative skills,
thereby offering a triangulation of methods that extends the range of research outcomes. These qualifications aside, social geography as a sub-discipline has entered the new millennium with considerable energy and momentum, if perhaps a less coherent subject matter.

**Social justice** A standard used to assess the fairness of a society. Justice is a central moral standard that requires the fair and impartial treatment of all. Social justice differs from other realms of justice, such as that relating to the application of law, being centrally concerned with the fairness of a social order and its attendant distributions of rewards and costs. Determining how fairness is to be assessed, and according to which principle, is an issue of fierce debate. Different criteria, including *equality*, entitlement, *recognition* or need, yield different principles of justice. While some scholars view social justice in essentially descriptive terms, the literature within fields such as geography has been more *normative*, with an emphasis on using some definition of social justice in the moral evaluation of prevailing social arrangements (see also *ethics*).

Social justice has long been a rallying cry for many social movements. The arguments of poor communities of colour that they are disproportionately burdened by environmental *externalities*, the claim by unions for better compensation or the democratization of the workplace, or the organizing of anti-capitalist globalization (*anti-globalization*) movements are all motivated, in part, by the powerful claim that prevailing social arrangements should be fairer. The injustice of many social relationships, distributions and arrangements has long been the focus of a rich scholarly and activist tradition (*activism*). Broadly, three perspectives can be identified:

1. The most extensive body of scholarship is to be found in liberal political theory that seeks variously to determine the essential characteristics of a 'fair' society (see *liberalism*). John Rawls' (1971) *A theory of justice*, for example, imagines an original position, prior to the creation of society. The just social order is that which those in this original position would agree to, he argues, if they did not know in advance whether they would be rich or poor in the resultant society. From this, he derives a number of yardsticks to assess social justice, of which the most famous is his 'difference principle', which holds that inequality can only be justified if it benefits the least advantaged.

2. Particularly influential within geography is a Marxist analysis of social justice (departing from one strain of *Marxism* that sees social justice as an ideological construct). Since his seminal *Social justice and the city*, David Harvey (1973) has been concerned with the topic, abandoning a liberal characterization as 'a matter of eternal justice and morality' in favour of a view of social justice as 'contingent upon the social processes operating in society as a whole' (p. 15). He judged questions of spatial distribution not according to the prevailing standard of efficiency but, rather, according to some measure of distributive justice. Social justice was said to apply to the distributions of benefits and burdens, as well as the social and institutional arrangements arising from production and distribution (including power, decision-making). In sum, he sought 'a just distribution, justly arrived at' (p. 98). In subsequent work, Harvey (1996) has extended his scope to include questions of *environmental justice*. While he acknowledges the importance of social difference and *positionality*, he continues to argue from *political economy*.

3. A *post-structuralist* reading of social justice supplements a Marxist emphasis upon class and economic relationships with the inclusion of multiple axes of social differentiation – such as *gender* and *race*. For example, while recognizing the injustices of class exploitation, Iris Marion Young (1990a) constructs a pluralist reading of oppression that includes marginalization, *violence*, powerlessness and cultural *imperialism*. She advocates a politics that 'instantiates social relations of difference without exclusion' (p. 227).

Social justice has been of occasional concern within geography since Harvey's original intervention. The collection edited by Merrifield and Swyngedouw (1997) for example, provides one example, as do recent arguments by Don Mitchell (2003a). Drawing, in part, from a Rawlsian analysis, David Smith
has also written thoughtfully on the topic. In an important paper, Smith (2000b) constructs a geographically sensitive argument for equality as a basis for social justice, and articulates an argument for the morally significant aspects of human sameness as a way out of the relativism of difference. Smith also considers the injustices of an uneven geography of global resource endowment as a basis for a territorial social justice. In a more post-structuralist vein, Kobayashi and Ray (2000) argue for a pluralist notion of justice that embraces positionality. They eschew a calculus of rights, with its logic of impartiality, arguing instead for an emphasis upon risk (cf. Peake and Ray, 2001). Noting that differently positioned people face differential exposure to injustice, they insist on the importance of geography to social justice. That said, social justice demands more careful and sustained attention by geographers. As Merrifield and Swyngedouw (1997, p. 2) note, it has all too often been relegated to the ‘hinterlands of academic inquiry’. For while social justice is often invoked, or implicit to much geographic work, particularly of a critical bent (critical geography), it is all too often left untheorized (although see the special issue of the journal Critical Planning, 14, 2007, which is dedicated to the theme of spatial justice: see http://www.spa.ucla.edu/critplan/).

**social movements** The organized efforts of multiple individuals or organizations, acting outside of formal state or economic spheres, to pursue political goals. They are commonly organized around either particular groups – for example, the working class – or particular goals – for example, access to health care. Their demands may be focused on the state (e.g. new laws), on economic actors (e.g. wage demands), on society as a whole (e.g. the changing of norms relating to race or sexuality) or on any combination of these. Social movements can radically transform society: consider feminism or environmentalism. Yet as loose networks of actors with many informal elements, they present methodological challenges: it is often difficult to show that a protest or NGO produced a effect; to determine whether a given actor is part of a movement; or to predict whether, when and how a movement will arise from given social conditions.

Early, major approaches to social movement theory conceived of social movements as phenomena within civil society, a sphere regarded as distinct from, but complementary to, the state and the market, one containing the informal norms and institutions necessary to the ongoing reproduction of the economy and the state, as well as forms of social participation and difference not strictly tied to economic class or legal citizenship status (see Urry, 1981). Marxist theories saw social movements, notably the labour movement, as direct results and expressions of political economic conflicts. Many early sociologists, following Emile Durkheim, adopted functionalist perspectives that interpreted social movements within organic, equilibrium-oriented conceptions of society; social movements were spontaneous phenomena produced by the need for individuals and groups in the rapidly shifting geographies and economies of modern capitalist societies to continually rebuild informal norms and institutions, create new relationships, and bring their material existences and expectations into alignment. From the 1960s on, liberal rational choice theories became dominant: Mancur Olson and others analysed social movements as collective action strategies by which rational individuals pursued their (calculable and known) self-interest. Interest consequently shifted from why social movements existed and what effects they produced, to a focus on how they pursued their goals. Questions regarding how movements mobilize resources and supporters, frame issues, identify and exploit political opportunities, and change over time dominated social movement theory for the subsequent few decades.

More recently, the ‘new social movements’ (NSMs) that have appeared and grown around the world since the 1960s have become central topics in the field. Theorists have argued that these NSMs, such as environmentalism and the peace movement, differ from ‘old’ social movements in critical respects. Posited differences include claims that NSMs: are more issue-specific; cut across class lines; use unconventional tactics; express not only instrumental goals, but meaning, identity and multiple subject positions; and are less likely to turn to established political parties and channels to achieve their goals. All of these claims warrant careful scrutiny. Most recently, geographers have begun to theorize how central geographic concerns such as space, place and scale matter in social movements’ formation and operations (Miller, 2000; Wolford, 2004; McCarthy, 2005).
**social network**  The people – especially kin, friends and neighbours – to whom an individual is tied socially, usually by shared interests and, in many cases, values, attitudes and aspirations. Most people are members of several such networks, which may overlap only slightly – in their home, family, neighbourhood, workplace and formal organizations, for example. Such networks may be spatially concentrated, as both cause and effect: people may choose to live close to others already in their network(s), and may develop ties with neighbours. Such networks are the main medium for interpersonal interaction, and therefore a core element of any social structure – hence concerns regarding the potential consequences of declines in their strength (cf. *social capital*).

Social networks provide the matrices through which much information flows and is evaluated. As such they are central components in models of change that involve interpersonal interaction, much of which has a spatial component (cf. CONTEXTUAL EFFECT; DIFFUSION; ELECTORAL GEOGRAPHY; NEIGHBOURHOOD EFFECT). They are often modelled formally as graphs, with individuals represented as nodes linked by ties along which information flows (see GRAPH THEORY): those ties can be evaluated quantitatively according to the intensity of interaction between the two individuals. Such a representation enables analyses of, for example, the key roles of certain individuals as nodes linking otherwise separate networks and their potential to act as change agents by channelling new information into a network. Research on such flows has suggested that weak ties (Granovetter, 1973) are often more important than strong ones as change stimuli. Strong ties usually link people with much in common whereas weak ties (links to acquaintances rather than friends, for example) may connect people with less in common, and therefore bring new information and ideas to their contacts.

Within GEOGRAPHY, the importance of social networks has been recognized in the study of economic organization and change, as in the development of new high-technology industrial regions (such as Silicon Valley in California: see Malmberg, 1997; Scott, 2006), in electoral studies (Huckfeldt and Sprague, 1995), and also in work on the exercise of POWER within policy communities, where interest groups interact with politicians and public servants. (See also ACTOR-NETWORK THEORY; NETWORK SOCIETY.)

Della Porta and Diani (1999); Laclau (1985).

**social physics**  An approach that suggests aggregate human SPATIAL INTERACTION can be explained and predicted using theories and laws from physics. H.C. Carey (1858) first codified social physics when he proposed that use be made ‘... of the great law of molecular gravitation as the indispensable condition of ... man [sic]’. But it was primarily John Q. Stewart (1950), professor of astronomy and physics at Princeton University, together with geographer William Warnitz (1965), who first systematically proscribed social physics under the rubric of MACROGEOGRAPHY, a short-lived movement, but one that helped pave the way for the subsequent success of SPATIAL SCIENCE within HUMAN GEOGRAPHY. The Newtonian GRAVITY MODEL remains the best-known example, suggesting that humans interact over terrestrial space as do heavenly bodies in the celestial system. The model gives a good empirical fit, but its predictions are less satisfactory, and its causal explanation worse. The lack of explanatory purchase, as Lukermann (1958) pointed out in a early critique, is because the assumptions made in the physical models are not met in the human realm: ‘the lacuna is of the order of two worlds’ (Lukermann, 1958, p. 2). There is nothing wrong with analogies per se, but for them to succeed there must be certain core similarities between the analogy and the analogized. For many critics of social physics, the similarities between human and celestial movements were not just hard to find, they were simply not there to be found.

**social reproduction**  The term encompasses the daily and long-term reproduction of the means of production, the labour power to make them work and the social relations that hold them in place. It includes the ‘fleshy, messy’ and diffuse stuff of EVERYDAY LIFE, as well as a congeries of structured material social practices that unfold in dialectical relation with production. At its most rudimentary, social reproduction is contingent upon the biological reproduction of the labour force – both day to day and generationally – through the production, acquisition, distribution

Barnes (1996, chs 4 and 5).
and/or preparation of the means of existence, including food, shelter, clothing and health care (Katz, 2001b). But any labour force is historically and geographically contingent, and so the notion extends to the reproduction of a differentiated and differently skilled labour force and the broad range of cultural forms and practices that create, uphold and rationalize these differences. Thus education, the legal system and mass media are arenas of social reproduction, helping to inculcate and naturalize what Pierre Bourdieu (1977) called the habitus.

Social reproduction is defined and secured through a fluid assemblage of sources associated with the state, capital, the household and civil society. The balance among these varies historically, geographically and by class, and its precise determinants are often the outcome of struggles in the workplace, community and home. If a social formation is to continue, then consumption, production, circulation and exchange – of goods, of knowledge, of values – must be ongoing. While social reproduction implies endurance, it should not be understood as stasis. Involving the lively practices of everyday life and the myriad efforts to secure these, social reproduction actively makes the conditions of ongoing production (cf. resistance). In this way, social reproduction is a critical concept: immanent in its material social practices is the possibility of rupture, renovation and transformation.

Social reproduction has political economic, cultural and environmental aspects. The first includes the reproduction of labour power, the material social practices that sustain class and other modes of difference, and the discursive and other work that makes these distinctions common sense. The cultural aspect of social reproduction includes the production and exchange of knowledge and skills, along with the spaces in which they are carried out and given meaning. This knowledge enables all forms of work, but also contributes to identity and social group formation as well. The environmental aspect of social reproduction refers to the making and maintenance of the forces and material grounds of production, including tools, machinery and factories, but also the environmental resources and political ecologies that enable ongoing production.

Social reproduction has been associated with Marxism, but much of the attention to it has come from feminists working in – or against – that tradition. This scholarship brings into critical tension the social relations of class, gender and sexuality, demonstrating the ways in which they build upon, strengthen or undermine one another under particular historical and geographical circumstances (e.g. Marston, 2000). Feminist geographers have also revealed the ways in which processes such as globalization, labour migration and economic restructuring are reworked by incorporating social reproduction in their analyses (e.g. Kofman and Raghuram, 2006).

social space With some notable exceptions, human geographers traditionally conceptualized space as a blank canvas upon which human activities are played out. This led to the adoption of an Euclidian notion of space and technologically astute attempts to map the way space is territorialized via economic, political and social action. In the social sphere, this reinvention of geography as a spatial science triggered multiple attempts to utilize census data to identify where residents shared similar characteristics or lifestyles, with techniques of social area analysis facilitating the identification of more-or-less homogeneous social areas. While some of this work perpetuated the ecological fallacy (implying that all persons in a given area shared similar social characteristics), more individually centred methods of social network analysis provided empirical evidence of the way in which individuals’ social worlds characteristically revolved around a localized set of social spaces. Here, the time-geography associated with Torsten Hägerstrand and the Lund School offered a different take on the spatiality of social practice, giving some important clues as to how social activities are distributed across time and space. Elsewhere, humanistic geography explored the emotional and even spiritual ties that bind societies to spaces, albeit often talking about the construction of place rather than the making of social space (Cresswell, 2004).

Reacting against these types of analysis, the historical and geographical materialism that emerged in the 1970s ushered in a rather different interpretation of spatiality, whereby space was deemed to be inherently caught up in social relations, both socially produced and consumed. Perhaps most influentially, Henri Lefebvre (1991b) insisted that there can be no ‘pre-social’ or ‘natural’ space, as, at the moment
that it is occupied through social activity, it becomes relativized and historicized space. Inferring that every society – and every mode of production – creates its own space, Lefebvre further distinguished between the abstract spaces of capitalism, the sacred spaces of the religious societies that preceded it and the contradictory and differential spaces yet to come. In outlining this history of the production of space, Lefebvre implied that the division of the world into a mosaic of social spaces is in no sense natural, but is a process that needs to be understood critically (and dialectically): in his words, ‘social space is a social product’ (Lefebvre, 1991b, p. 32: see dialectic).

The idea that space is not passive in the constitution of society is now dominant in human geography, manifest in numerous studies of the conflicts inherent in both the production and consumption of social space. Key here is the notion that these conflicts are not necessarily between different groups, but are between different forms or conceptions of space (Shields, 1991). Adapting Lefebvre’s terminology, it is suggested that spontaneous and fully lived ‘spaces of representation’ may often clash with official ‘representations of space’, with the former occasionally breaking through abstract capitalist logics to produce differential spaces. Studies of spatial practices as diverse as skateboarding, tagging, driving and free-running may thus point to the possibilities of producing new social spaces where human sociality is given full reign and where play is privileged over work (Thrift, 2003; Latham and McCormack, 2005). In this regard, the rise of non-representational theories can be interpreted as an important part of geographers’ ongoing attempts to elucidate the materialities rather than just the meanings of social space.

Social theory This term refers to a constellation of theories about what Giddens (1984) terms ‘the constitution of society’, specifying the mechanisms or the forms of social power that lend society some overall shape and coherence, however precarious, within given territorial limits (extending in some theories to the whole globe). Callinicos (1999, p. 1) states:

Social theory . . . has concerned itself . . . with the three main dimensions of ‘social power’ – economic relations, which have reached their furthest development in the market system known as capitalism; the ideologies through which forms of special power are justified and the place in the world of those subject to them defined; and the various patterns of political domination.

Social theory can be distinguished from philosophy, which addresses epistemological and ontological issues pertaining to the nature of knowledge that we acquire, develop and relate about the world, its social contents included. In practice, however, social-theoretic and philosophical questions run closely together, and in many reviews of human-geographical theorizing the two are presented in an entangled (and perhaps on occasion confused) manner. Different social theories embrace a raft of varying assumptions, arguments and models about how economy, politics and culture play out in social power, and perhaps too bringing in claims about psychology, mythology and many other domains of human being and endeavour. All manner of economic, political, cultural and other theories abound, deriving from diverse disciplinary fields, alongside theories about how these different domains interrelate, influence or even determine one another in the social. All of this complicated material comprises the ‘house’ of social theory that has been repeatedly visited, borrowed from, critiqued and reworked by geographers down the years.

The ‘predisciplinary history’ of social theory can be traced to Europe in the period 1750–1850 (Heilbron, 1995), anchored in how the enlightenment encouraged abstracted reflections upon the social character of the times, but its origins are usually identified with several major thinkers who continue to cast a long shadow over the contemporary academy. The pantheon here includes the ‘big three’ of Karl Marx, Emile Durkheim and Max Weber, the key figures of so-called ‘classical social theory’, as well as various others – Herbert Spencer, Georg Simmel, G.H. Mead, Talcott Parsons, the Frankfurt School theorists – bridging forward into ‘modern social theory’, and then another cast-list – Anthony Giddens, Richard Rorty, Ulrich Beck and various French intellectuals – deemed, if a touch misleadingly, exponents of ‘postmodern social theory’ (see postmodernism: for equivalent periodizations, see Lemert, 1993; Callinicos, 1999). The term ‘social theory’ was clearly in use by the early twentieth century, and it appeared in modern-sounding guise when Merton
(1957) talked about ‘social theory and social structure’.

The level of engagement between geographers and social theorists has been highly uneven: Marx receiving far more explicit attention than, say, Durkheim and Weber; or the French ‘postmodernists’ (Baudrillard, Derrida, Lyotard, Foucault) more than, say, the Frankfurt ‘modernists’ (Adorno, Habermas, Horkheimer). Through Giddens (1979), a binary distinction is sometimes detected between the social theories on offer, cleaving a deterministic, functionalist pole of explanation from a voluntaristic, interpretive–hermeneutic pole of understanding, and this distinction has been usefully mapped into critical accounts of human geography’s underlying social-theoretic allegiances (e.g. Thrift, 1983). In return, geographers have been injecting a spatial sensibility into the heart of social theory, a project that, while initially formulated within the latter by Giddens (1979, 1984), has now announced geography as a ‘player’ within social theory. The Gregory and Urry (1985) and Benko and Strohmayer (1997) collections indicate how far and quickly this project developed after the late 1970s: contributions from the likes of Soja (1989), Gregory (1994) and Massey (2005) have all worked on advancing space in social theory (see GEOGRAPHICAL IMAGINATION). The founding of the journal Society and Space in 1983, configured as a meeting-place between social theory, human geography and cognate ‘spatial’ disciplines, embodies how something new, social-theoretically driven, was to become (for many) what necessarily lies at the heart of a human geography escaping from disciplinary isolation.

Unsurprisingly, the pantheon of social theorists listed above has attracted criticism, in part from those objecting to a too-easy eliding of social theory with the ostensible goals and exclusions of Enlightenment: namely, its trumpeting of (certain visions of) progress, reason and scientific protocols, together with the predominantly bourgeois, white, male identities of the thinkers involved. Alternative, anti-Enlightenment social theorists of the period are hence erased from the history (Mestrovic, 1998), as too is the awkwardness that the original social theorists often felt themselves about both the emerging modern world and the intellectual tools available to them. More starkly, the classed, raced and gendered dimensions of social theory, embedded within a Euro-Americanism, are now highlighted (Slater, 1992). Lemert (1993, p. 10) dissects the issues here, linking with the ‘culture wars’ afflicting North America (and to an extent elsewhere in the west too):

There are those who insist that, whatever has changed, America and the world can still be unified around the original Western ideas that Arthur Schlesinger described as ‘still a good answer – still the best hope’ . . . Schlesinger – white, male, Harvard, liberal, intellectual, historian – is the most persuasive of those in this camp. Against them are others who say, ‘Enough. Whatever is useful in these ideas, they don’t speak to me.’ Audre Lorde – black, feminist, lesbian, poet and social theorist – put this opposing view sharply in an often-quoted line: ‘The master’s tools will never dismantle the master’s house.’ Between these two views, there is more than enough controversy to go around. In large part, the controversy is between two different types of social theorists and over how social theory ought to be done.

One result has been the rise of FEMINIST, anti-racist and POST-COLONIAL versions of social theory, perhaps deriving from ‘other regions’ (Slater, 1992), alert to the fundamental structuring of the social by the cross-coupling of unequal power relations at a range of spatial scales and in/through a variety of places. A further implication, resonating (if a shade ironically) with the ‘postmodern social theorists’, has been to challenge all versions of social theory (old and new) by suggesting that their claims are always too grand, totalizing, inflexible and insensitive to the specificities of (the ‘real’ histories and geographies of) EVERYDAY LIFE (cf. GRAND THEORY). Consequently, ‘social theory is often seen in contemporary intellectual debates as an outdated form of understanding,’ which means that, ‘[t]hough . . . no one has yet announced the end of social theory, someone is bound to get round to it sooner or later’ (Callinicos, 1999, p. 1). In effect, such a move has occurred in recent geographical texts, with calls for ‘minor theory’ (Katz, 1996) and ‘modest theory’ (Thrift, 1996), thereby leaving social theory in an odd place, demonized but still indispensable, if only as the ever-present horizon of what needs to be argued against or at least around (the spirit of Pryke, Rose and Whatmore, 2003). In this fractured intellectual landscape, social theory does not disappear: it is not wholly redundant, but it does acquire a curious character as a resource to be quarried for
cautious insights into this thing, society, that is now acknowledged – much more than ever before – as a complicated, provisional, neverfully-formed, always becoming object. CP

social well-being The degree to which a population’s needs and wants are being met. In a well society operated on market principles (see economic integration), people have sufficient income to meet their basic needs plus additional money to be used for discretionary spending, are treated with equal dignity (see human rights), have reasonable access to all public services, and have their opinions heard and respected (cf. democracy). Levels of social well-being vary across groups and places within societies. Measuring variations in those levels was part of the social indicators movement initiated in the 1960s and taken up by geographers with analyses of territorial social indicators. socialism Modern socialisms have their origin largely in nineteenth-century European working-class struggles against the predatory, unequal and degrading consequences of industrial capitalism and twentieth-century industrial and agrarian struggles against imperialism. Thus, if capitalism is a social and economic system in which ‘the ownership and control of real capital are vested in a class of private “capitalists”’, whose economic decisions are taken in response to market influences operating freely under conditions of laissez-faire’ (Crosland, 1970, p. 33), socialism seeks to change the ways in which capital–labour relations are organized and social surplus is distributed (see anarchism; marxism).

Historically, the socialist allocation of social surplus has sometimes been organized through collective ownership or by the state (state socialism), and has required planning and control mechanisms to regulate the economy. Since the nineteenth century, some socialists have supported the complete nationalization of the means of production, others have been more interested in worker democracy and decentralized ownership (either in the form of cooperatives or workers’ councils), and yet others have proposed selective nationalization of commanding heights industries in the context of mixed economies.

Recent neo-conservative and neo-liberal theories and policies have greatly weakened the popular legitimacy of socialism in many parts of the global North, but political movements in the global South (notably in South Africa, Venezuela and Bolivia) have renewed commitments to socialist parties and principles. In countries such as Portugal, Spain, Greece, Italy, Argentina and Mexico, socialist movements have emerged deeply suspicious of political projects that seek to seize the state and, instead, have articulated new claims for socialist autonomous political projects in which vanguardist theories of social action have been reworked and inflected with new alignments of socialist theory with anarchist and autonomous practices (what Derrida (1994) called the ‘New International’ and Hardt and Negri (2004) refer to as the new communism). Partly as a result of these broader movements in socialist practices and stimulated by the consequences of increasing integration into the global economy, reformed socialism has also emerged in former (post-socialist) and current state-socialist societies throughout Europe and Asia, perhaps most notably in China. In Europe, discussions of alternatives to neo-liberalism correspond with strong debates about the possibility of a social Europe, predicated on protections for social rights, social cohesion and a social market, while in China experiments with market socialism and Deng Xiaoping’s advice that ‘To get rich is glorious’ are rapidly transforming the conditions of social life and environment throughout the country.

The impact of socialist thought and practice among geographers has been significant, particularly in their analyses of the geographies of social movements and socialist politics. Geographers such as Peter Kropotkin, Élisée Reclus and others were closely engaged in debates about socialism and anarchism, while others – such as the English socialist J.F. (‘Frank’) Horrabin (1884–1962) – worked to construct a socialist geography through the Labour party, the Fabian Society and groups involved in working-class education, such as the Plebs League and the National Council of Labour Colleges (Hepple, 1999). In the post-war era, particularly with the emergence of strong civil rights, anti-colonial, anti-war and anti-nuclear movements, socialist geographies emerged in a wide range of arenas, generating strong interest in the institutional and
intellectual development of socialist approaches to geography (through the Union of Socialist Geographers (started in 1974), *Antipode*, the Socialist Specialty Group in the Association of American Geographers, and the International Critical Geography Conference) (see Dear, 1975). At the centre of many of these developments in geography has been the towering figure of David Harvey. Since the 1970s, Harvey has systematically argued for the importance of the geographical imagination for understanding capitalism and socialist (Marxist) critique. From the 1990s, he increasingly extended these efforts beyond geography through his writing and speaking engagements with the Socialist Register, New Left Review, Monthly Review and the Brecht Forum, among many others (Castree, 2007).

society A widely used term whose meaning remains frustratingly vague, but that describes the organization of human beings into forms that transcend the individual person, bringing them into relations with one another that possess some measure of coherence, stability and, indeed, identifiable ‘reality’. The one-time UK Prime Minister Margaret Thatcher infamously declared ‘there is no such thing as society’, offering a populist version of a position in social science known as methodological individualism (Werlen, 1993 [1988], pp. 40–52) that ultimately lodges all social enquiry in the attitudes, goals, decisions and behaviours of individual human actors. Even within critical strands of social theory/social science, however, the notion of society remains curiously taken-for-granted, under-theorized and even an embarrassing guest that certain perspectives within the contemporary theoretical landscape – various forms of post-structuralism, for instance, or actor-network theory (ANT) and non-representational theory (NRT) – might wish had never arrived.

Many concepts of society set it apart from economy, politics and culture, such that it (or something called ‘the social’) becomes a distinctive ‘level’ for analysis, apparently made of ontologically different stuff, with questions prompted about whether it exists in relations of influencing, co-influencing or being influenced by these other levels. More specifically, notions such as civil society have been developed to distinguish a sphere of human concern and activity that cannot be reduced to either the dynamics of economic production or the machinations of the state (Urry, 1981), although debate then rages about whether a ‘capital-logic’ or ‘state-centric’ account of civil society is more appropriate (a question that arguably can only be answered by researching particular forms of [civil] society found in particular times and places). Alternatively, many social theories tackling what Giddens (1984) terms ‘the constitution of society’ discuss how dimensions of the economic, the political and the cultural all bolt together to create society, wherein society appears as the product, articulation or condensation of all of these dimensions rather than as something somehow separate (and separable) in its own right. Inevitably, though, different social theories suppose differing balances between these constitutive dimensions of society, with some leaning towards economic determinism and others towards what might be called political or cultural determinism. Other perspectives, meanwhile, query the very construct of ‘society’, regarding it as at best a name for a loose assemblage of objects – people, to be sure, but also diverse non-human actors (books, bullets, newspapers, telephones, hospitals, streets etc.) – that have to be constantly enlisted by people in practices that produce, sustain and render with some semblance of ‘reality’ a patterning that can be understood and re-presented (to others) as ‘society’. Although proceeding with different (post-structuralist and practice-attuned) theoretical tools, Thrift (1996, pp. 30–5) draws out the implications of Copjec’s (1994, pp. 8–9) psychoanalytically informed insistence that ‘society never stops realising itself, that it continues to be formed over time’, a claim rebounding in various ways on the static ontologies and epistemologies inherent to many conceptualizations of society.

Thrift (1996, p. 56), reflecting upon his early borrowings from Giddens’ social ontology, still finds things here to praise but concludes that ‘one cannot fill out all of a society in the way Giddens sometimes . . . seems intent on doing’. This being said, through his structuration theory, Giddens has arguably done more than most to disentangle the different elements that many writers, geographers included, continue to take as indispensable for any account of something called ‘society’. The elements here include: the agency of individuals, socialized into certain habits of thought, conduct and action, if always possessing the capacity to think and do things differently; institutions, entailing formal entities with written constitutions, regulations, memberships and so on (e.g. schools, firms, clubs) as well as informal but enduring entities such as family
and religion, reproduced every day by the repeated practices of many individuals (a notion of social reproduction); systems, or regularized patterns of interaction between individuals often but not always functioning to keep institutions going (and in some vocabularies, ‘institution’ and ‘system’ become interchangeable); and structures, or ‘deeper’ structural forces underpinning systems, institutions and (the being and doing of) individuals, often understood in terms of unequal relations of power, status and influence traversing axes of social difference (notably of class, ethnicity and gender, but also the likes of ageing, sexuality and disability). In such Giddensian theorizing, the focus is on how society arises – is ‘instantiated’ – in the coming together of agency and structure, made real by actions mediated through institutions and systems, and there is also a recognition that time–space relations are crucial to the precise manner in which this coming together occurs (Giddens, 1979, 1984; Gregory, 1981, 1994; Thrift, 1983; Werlen, 1993).

There has long been a relationship between geographical scholarship and notions of society, and one simple point is that geographers have often had a sharper sense than others of the exact worldly spaces to which different picturings of society commonly attach. On one reading, this means nothing more than recognizing that accounts of society are normally referencing particular territorial units (Pain, Burke, Fuller and Gough, 2001, p. 3): perhaps (nation-)states with known boundaries (i.e. ‘Bulgarian society’); perhaps commonly understood regions large or small (i.e. ‘Mediterranean society’ or ‘Appalachian society’); or perhaps still smaller, more local areas (i.e. London’s ‘West End society’). The implication of moving down spatial scales, as here, is to reveal that dangers accompany any identification of one society (with allegedly distinctive features) occupying or filling a large spatial extent, and that closer geographical scrutiny will always require a more nuanced portrayal of the different societies there present. On another reading, geographers have been prominent in acknowledging that urban and rural localities possess different sorts of societies, with the classic distinction drawn by the German sociologist Ferdinand Tönnies between Gemeinschaft (close-knit society or community, based on repeated face-to-face contacts) and Gesellschaft (weakly bound society, based on impersonal, contractual relations) mapped on to, respectively, the countryside and the city. Such a mapping has to be treated with caution, however, and many practitioners of urban and rural geography would insist that any given urban or rural area, wherever located, is unlikely to possess just one, homogeneous, internally consistent society. Crucially, what emerges is the appreciation that society is not a singular entity, undifferentiated from one place to the next, and that scholars – not just geographers, but all informed intellectuals – should think in terms of many societies in the plural.

In works of geography, it is possible to find countless casual references to ‘society’. As one instance, Kariel and Kariel (1972) define social geography as the ‘study of the spatial aspects of characteristics of the population, social organisation, and elements of culture and society’ (p. v, footnote; emphasis added), but never define nor explain what society means for the remainder of their text (which deals with the spatial patterns displayed by a range of phenomena such as food, buildings, language and religion). The lack of a definition of society is also true of more recent social geography texts (Valentine, 2001; Panelli, 2004), although the explicit concern here for social groupings, categories and relations means that the reader arguably emerges with a greater sense of what the social entails. One current text does provide a definition, however, noting how: ‘“Society” denotes the ties that people have with others. . . . Societies are usually perceived as having a distinct identity and a system of meanings and values which members share’, (Pain, Burke, Fuller and Gough, 2001, p. 3, box 1.3). It is possible to find geographers leaning towards all of the theoretical positions laid out above and more, but many have been drawn to the loosely Giddensian formulation, complete with its alertness to time–space relations.

Finally, it is interesting to reflect upon how different geographical traditions have worked, unwittingly or more knowingly, with different conceptions of society, and in the process started to theorize in different ways the relations between society (the social) and space (the spatial). Tracing such differences across the twentieth-century history of human – or, more narrowly, social – geography is the task that Philo and Söderström (2004, esp. p. 106) set themselves, probing ‘the work of geographers trying to make sense of “the social” by their own means, including their own bricolage of elements culled . . . from a diversity of sources in social theory, other disciplines and popular discourses’. Environmental, regional, spatial, radical, humanistic and
‘culturally turned’ geographies are all examined, drawing from Anglophone and French literatures, and questions are asked about how and why particular scholars on particular occasions have chosen to talk about society or the social, and with what consequences for the varieties of human geography practised. More overtly, it is now possible to identify diverse strands within human geography over the past quarter century that have been explicit in seeking to theorize the relations between society and space. Following Soja’s (1980) statement of the ‘socio-spatial dialectic’, a range of contributions, at first chiefly based in a Marxian tradition, but subsequently enriched by insights from feminism, post-colonial theory, cultural theory, psychoanalysis and elsewhere, have illuminated the problematic of simultaneously articulating ‘the societal construction of space’ and ‘the spatial construction of society’ (see feminist geographies; Marxist geographies; post-colonialism; psychoanalytic theory). In so doing, the very referents ‘society’ and ‘space’ have been subjected to intense questioning, in some literatures being deconstructed to the point at which the terms appear to be under permanent erasure; but they will persist, their names will be invoked, and the problematic of ‘society-space’ will continue as an unavoidable challenge to generations of geographical theorists to come.

Software for qualitative research
Some qualitative research methods generate large quantities of ‘data’ for which computer-based software has been developed. Most of the available software packages focus on the analysis of textual (including transcribed interview) material and undertake various forms of content analysis through a variety of user-informed coding schemes. Among the early such packages, NUD*ist (Non-numerical Unstructured Data [for] index searching and theory-building) was particularly popular: it facilitates indexing and the structuring of indexes as well as rapid searches for words and phrases and producing statistical reports on, for example, word associations and allowing researchers to insert memos within the text. More recent developments building on that foundation include NVivo and XSight: all privilege certain approaches to textual analysis – focusing on associations and counting – and thereby to some extent constrain if not direct the enterprise. As with software for quantitative analysis, an increasing number of freeware packages is available for interrogating qualitative data – such as those made available through CAQDAS (Computer-Assisted Qualitative Data Analysis).

Software for Quantitative Analysis
Software, a term invented by the statistician John Tukey, refers to the instructions executed by a computer, as opposed to the hardware, the physical device on which the software runs. Over the past 40 years, statistical software has revolutionized the way in which we approach data analysis, by allowing a much more computationally intensive approach. This has led to working with much larger data sets; using more realistic models (e.g. Categorical Data Analysis; Geographically Weighted Regression; Multi-Level Models); and better ways of visualizing data sets and models (see Visualization) as part of an exploratory data analysis approach. However, Ripley (2005) argues that ‘software availability now drives what we do, probably much more than we consciously realize’: if it is not readily available, we tend not to do the analyses. This has been particularly problematic in holding back development and adoption of geographical modeling and spatial analysis, because the widely used and otherwise reasonably comprehensive software, such as the Statistical Package for the Social Sciences (SPSS), has limited capacity in this area. This is finally changing and a new generation of software (much of it ‘freeware’) has these capabilities, as in the table on page 703.

South, the
Invoked implicitly or explicitly in relation to its assumed opposite (the North), the idea of the South emerged as an alternative to the term THIRD WORLD for distinguishing former colonies and less industrialized nations from countries of the more affluent and industrialized North. South is preferred by those who see Third World as connoting third-ranked, rather than its original meaning of a non-aligned or third path, independent of the capitalist First World and the socialist Second World. However, the term ‘South’ is also problematic in that the countries of the South are (a) defined through their location with respect to the USA and Western Europe, and (b) concentrated in the tropics and sub-tropics of both the Northern and the Southern Hemispheres. To avoid such binaries, some scholars deploy the language of a ‘One Third (1/3) World’ – typically in conjunction with the notion of the ‘First World/North’ – and a ‘Two Thirds (2/3) World’ in conjunction with a ‘Third World/South’ to represent the relative fractions of global population based on quality of life (Mohanty, 2003).

The popularization of the terms ‘South’ and ‘North’ is sometimes attributed to the publication of two reports by the Brandt Commission: North–South (1980) and The Common Crisis (1983). Convened by Willy Brandt of the then West Germany to study critical issues arising from the economic and social disparities of the global community, this self-appointed commission highlighted a dependent relationship between the northern nations, which relied on the wealthier North for their wealth, and the southern nations, which depended on the wealthier North for their development. With food, agriculture, aid, energy, trade, financial reform and global negotiations as their focus, the Brandt Reports sought to promote ‘adequate solutions to the problems involved in development and in attacking absolute poverty’, while also addressing issues concerning the environment, the arms race, population growth and the uncertain prospects of the global economy that the commission viewed as common to both North and South (Brandt Commission, 1980; Porter and Sheppard, 1998, p. 26).

However, it is in the post-Cold War era that the idea of the South became significant as a metaphor to define the global landscape of political and economic power. Throughout the 1980s, the two rival Cold War military and political systems shaped development possibilities in the Third World. While relations between either superpower bloc and the Third World frequently provided only limited development opportunities for recently decolonized nations and Latin America, Third World leaders did have some choice of political economic system. This room for manoeuvre was at times exploited by Third World elites to resist capitalist or communist incursion, and to develop social democratic and Welfare State systems (see Capitalism; Communism). The period after 1989
witnessed the demise of the SECOND WORLD, the rise of the USA as the dominant economic, ideological and military power, and the hegemony of neo-liberal economic discourse (see NEO-LIBERALISM). East–West rivalries have been replaced by NORTH–SOUTH tensions around such issues as the power and role of the WORLD TRADE ORGANIZATION, the United Nations and international finance institutions, global CIVIL SOCIETY and donor-driven NGOs, mobility of labour versus that of CAPITAL and COMMODITIES, and public health crises related to AIDS (Sheppard and Nagar, 2004).

However, Mamdani’s (2004, p. 250) point that ‘the Cold War was largely not fought in Europe but in what came to be called the Third World’ serves as an important reminder that the East–West politics have been at all times North–South politics. Not surprisingly, then, while the post-9/11 ‘anti-TERRORISM’ discourse is couched in terms of West versus radical Islam, the US war on terror has simultaneously metamorphosed into an offensive imperial war, in which southern nations are denied the right to defend their SOVEREIGNTY as well as the right to reform (Mamdani, 2004, p. 260).

Two noteworthy fissures in the concept of the South have emerged in this environment. First, with the emergence of the so-called newly industrializing countries (NICs), such as Taiwan and South Korea, and growing impoverishment, particularly in AFRICA, the countries of the South have become increasingly differentiated. Second, whereas East–West rivalries predominantly played out at the NATION-STATE scale, North–South tensions operate on multiple SCALES. As political and economic elites in most countries of the Third and erstwhile Second Worlds accepted the tenets of neo-liberalism, they repositioned themselves ideologically and materially alongside the more wealthy residents of the First World. At the same time, ongoing socio-economic polarization within the industrialized world (reinforced by post-9/11 reforms), together with the devolution of responsibilities for citizens’ welfare from nation-states to regions and cities, has meant that livelihood possibilities in marginal localities within the former First World become more similar to those of the less well off in the former Second and Third Worlds than to the elites in their own countries. In addition, multilateral and supra-national agencies became increasingly influential proponents of the neo-liberal agenda of the global North, shaping development geographies within states (Sheppard and Nagar, 2004).

In concert, donor-driven NGOs have facilitated the co-optation of radical left and feminist politics, even as they have helped to popularize the concepts of empowerment and equity in limited but critical ways. Not surprisingly, then, the proliferation of UN conferences on women in the post-Cold War era has ‘undermin[ed] nation-specific resistance in the name of international solidarity’, while simultaneously creating ‘“the new subaltern” – the somewhat monolithic woman as victim who is the constituted subject of justice under (the now-unrestricted) international capitalism’ (Spivak, 2000, p. 305).

Thus, the global North is constituted through the pathways of transnational capital and NETWORKS of political and economic elites spanning privileged localities across the globe (Castells, 1996a; Mohanty, 2003). By contrast, the global South, which theoretically inhabits the ‘margins’, is to be found everywhere. But this does not make all Souths ‘equal’. Movements against neo-liberalism are reminders of the ways in which convergences and divergences on issues such as livelihood alternatives shape the agendas of actors operating in multiple Souths, whose visibility, in turn, is shaped by complex politics of socio-geographical locations (Glassman, 2002; Hardt, 2002; Sparke, Brown, Corva, Day and Faria, 2005).

sovereign power A philosophical concept arguing that POWER is the control over individual life. The concept is a challenge to established ideas of SOVEREIGNTY that concentrate upon political authority over TERRITORY. Sovereign power focuses attention to the SCALE of the BODY, the authority to classify individuals in a particular way to grant them life or death. The roots of the concept lie in the work of Michel Foucault and his discussion of BIOPOWER, regularization and BIOPOLITICS. Foucault’s analysis of nineteenth-century medicine and sexual behaviour described the way in which individual bodies and sexual practices were classified by STATE institutions as healthy/good and unhealthy/bad. The manner in which this was done led to the regulation of individual behaviour, or biopower, through classification and control, to the classification of groups of people (in terms of RACE, NATION, SEXUALITY, GENDER etc.), the political implication being that classification of people as, say, sexually deviant can be used in arguments limiting their political RIGHTS.

Usage of the concept ‘sovereign power’ has been promoted by the work of Giorgio
Agamben, who thought that the fate of the Jews in the HOLOCAUST ran counter to Foucault’s theory. Instead, Agamben argued that at times individuals and groups may be classified in such a way that their life is deemed worthless rather than something to be regulated. For Agamben, the Nazis identified Jews as ‘bare life’—life that warranted extermination. Agamben begins with the Romans, and their classification of homo sacer (from Roman law, an individual who may be killed but not sacrificed). Homines sacri may not be sacrificed as they are ‘beyond the divine’, and hence meaningless to the gods. They may be killed with impunity, however, because homo sacer is beyond juridical law, and hence has no value to the citizenry. While Foucault examined how power disciplined individuals to create a subject (a person behaving within imposed rules and norms), Agamben argued that sovereign power allows for the elimination of particular subjects. Foucault’s biopolitics tries to define who can and should be included in a political community, while Agamben argues that sovereign power excludes individuals and groups not just from particular territorial political communities but from humanity itself.

Geographers have utilized the next logical step in Agamben’s work, his identification of spaces of exception (see EXCEPTION, SPACE OF); the geographical construction of borders outside which the rules and norms of established legal and political order do not apply. It is in these geographical zones that sovereign power allows and enacts the killing of homo sacer with impunity. The classification of territory in this way results, for Agamben, in a mapping of our world not into nations, but into ‘camps’. In the context of the ‘war on terror’, Agamben’s concept was used by geographers to explain the slaughter of fighters and civilians by the US military in Afghanistan and Iraq, the violence upon the Palestinians by Israeli forces, and the incarceration of ‘terrorists’ at the US Naval Station at Guantánamo Bay, Cuba, with no recourse to US or international law (Gregory, 2004b).

**sovereignty** A claim to final and ultimate authority over a political community. The Treaty of Westphalia (1648) codified modern politics as a system of states: states have sovereignty over the land and people in their territories. The term implies that no external political entity has the authority to enact laws or exercise authority within a sovereign territory (Taylor, 1994c, 1995b). In reality, such a condition of sovereignty has never existed and has been particularly challenged by contemporary processes of globalization.

Sovereignty of states in an inter-state system is the result of two interrelated processes. First, *internal sovereignty* means that external powers are excluded from exercising authority within a state’s territory, and that the state has authority over the whole of its territory. A distinction must be made between legal and effective sovereignty. A state may claim sovereignty over the whole of its territory but face strong opposition and resistance to its rule in particular regions to the extent that the state apparatus is ineffective and ignored. Second, *external sovereignty* means mutual recognition from other states in the system, ultimately requiring endorsement by, and membership of, the United Nations. For example, Israel’s induction into the United Nations in 1947, despite protest from Arab countries, established the new state in the inter-state system.

The sub-discipline of political geography was initially focused upon issues of sovereignty, especially the precise location of the borders that delimit states and their sovereignty, as well as the functional internal geography that facilitated the effective exercise of sovereignty. In addition, the fact that state sovereignty did not produce peace, as intended and expected, but has generated conflicts has also provided topics for political geographers: inter-state conflicts, IMPERIALISM and SECESSION, for example. Furthermore, sovereignty over the sea and inner and outer space have emerged as important topics.

The most intriguing discussions of sovereignty have emerged in light of globalization, and the extreme argument, made by some, that we are facing the end of state sovereignty as it emerged in modern times (Ohmae, 1995). Before discussing globalization and sovereignty two points must be made. Sovereignty as per its definition has never existed; there have always been interdictions of external authority and challenges to internal sovereignty. Second, globalization is not an external force acting upon states, but a collection of economic, political, and cultural processes that are partially created and enacted by states. The undermining of state sovereignty by globalization is partly a result of the states themselves. This has led to the definition of ‘quasi-states’, those that have limited effective
sovereignty, often an outcome of post-colonial relationships (Jackson, 1990).

The inter-state, or even trans-state, character of globalization has weakened the ability of states to manage their own economic affairs. Currency values and interest rates within particular countries are partially set by the decisions made by international markets rather than through domestic policy, for example. In other words, external influence is felt within sovereign territory. The outcome is a geography of ‘graduated sovereignty’, in which state sovereignty is spatially differentiated within a sovereign territory (Park, 2005). For example, special economic zones of reduced taxes and tariffs are established within countries that reduce the fiscal authority of the state in order to promote trade and investment (cf. enterprise zone).

Although states have ceded sovereignty over economic processes, others, reacting to public pressure, have focused upon social sovereignty (Rudolph, 2005), defined as the states’ ability to define and control access to a political community. Political citizenship has been understood as a feature of territorial sovereignty; citizenship was attached to a particular territorially-defined community, and citizens gained rights and received duties from the sovereign state. However, processes of globalization have led to increased calls for non-territorial forms of citizenship, in effect granting sovereignty to institutions that transcend states (Russell, 2005).

Sovereignty is in a state of flux, as society becomes increasingly organized around networks rather than territories (Castells, 1996b). Consideration of graduated sovereignty is coupled to overlapping forms of sovereignty, akin to pre-modern times, whereby a territory may be subject to a number of sovereign claims. Some of these claims may be stronger and more appealing than others as the ability to exercise authority may decline with distance from a political centre (Lake, 2003). Currently, we live in a hybrid political geography of varying forms of sovereignty within territorial and network spaces. CF

space The production of geographical knowledge has always involved claims to know ‘space’ in particular ways. Historically, special importance has been attached to the power to fix the locations of events, places, people and phenomena on the surface of the Earth and to represent these on maps. The extension of these capacities involved a series of instrumental, mathematical and graphical advances, but these innovations were also political technologies that were implicated in the production of particular constellations of power (Pickles, 2004; Short, 2004). As such, they carried within them particular conceptions of space that were always more than purely technical constructions (see also cartography, history of). This recognition of an intricate connection between power, knowledge and geography has transformed the ways in which contemporary human geography has conceptualized space. A suite of theories and concepts has been assembled to address what Allen (2003) describes as both ‘spatial vocabularies of power’ (which trace the mobilizations and effects of power over space) and ‘lost geographies of power’ (which show how power is produced and performed through space). These elaborations have significant repercussions for concepts such as place, region and territory, but in what follows attention is directed towards the more general, plenary concepts of space within which these more particular concepts may be convened.

These are matters of considerable importance. Many writers have argued that the nineteenth century was the epoch of time, the twentieth century the epoch of space, and that as ‘the modern’ yielded to ‘the postmodern’ so there has been a marked ‘spatial turn’ across the spectrum of the humanities and social sciences that describes much more than the play of spatial metaphors (e.g. Smith and Katz, 1993; Soja, 1989). But others have insisted on the imminent ‘end of geography’, ‘the irrelevance of space’ and the ‘death of distance’ in ostensibly the same late, liquid or postmodern world (e.g. Bauman, 2000a). It is not difficult to reconcile these competing claims: everything depends on how ‘space’ is conceptualized (cf. modernity; postmodernity).

Hartshorne’s once influential enquiry into The nature of geography (1939) occupies a strange position within the history of the discipline. His view of geography was Kantian – Geography was concerned with the organization of phenomena in space (see areal differentiation; Kantianism) – and yet Hartshorne provided no systematic discussion of the concept on which his prospectus depended. Even his subsequent account of geography as one of the ‘spatial sciences’ (with astronomy and geophysics) failed to elucidate the conceptual basis of his claim. What
preoccupied Hartshorne (1958) was the recovery of a line of descent from Kant through Humboldt to Hettner, and yet the ways in which these writers conceptualized space was never allowed to become a problem. Hartshorne simply took it for granted that space (like time) was a universal of human existence, an external coordinate, an empty grid of mutually exclusive points, ‘an unchanging box’ within which objects exist and events occur: all of which is to say that he privileged the concept of absolute space (Smith, 1984, pp. 67–8).

Many of Hartshorne’s postwar critics fastened on the way in which he had taken a specific concept of space and elevated it to the single, supposedly universal concept of space. Although Schaefer objected to the exceptionalism of Hartshorne’s views, he nonetheless agreed that ‘spatial relations are the ones that matter in geography and no others’. The difference was that spatial relations were now to be defined between objects and events (not between the fixed points of an external coordinate system) and thereby made relative to the objects and events that constituted a spatial system or spatial structure. This substituted a concept of relative space whose elucidation required a more complex geometry, and for this reason spatial analysis – the preferred research methodology of many of Hartshorne’s critics – involved a process of abstraction in which ‘physical space [was] superseded by mathematical space’ (Smith, 1984, pp. 68–73). This intellectual project promised to turn geography into a formal spatial science, predicated on a key claim: ‘That there is more order than appears at first sight is not discovered till that order is looked for’ (Haggett, 1965, p. 2). This was used to demarcate a new research frontier – a ‘new geography’ – whose explorer–scientists believed that there was an intrinsically and essentially spatial order to the world: that spatial science made it possible to disclose (to make visible) the spatiality of the natural and the social in ways that were literally overlooked by the other sciences.

Yet many human geographers became increasingly uncomfortable at what they saw as both spatial fetishism (treating social relations as purely spatial relations) and spatial separatism (divorcing human geography from the humanities and social sciences). The critique of spatial science was many-stranded, but many of the original objections revolved around Olsson’s (1974) insight that the statements of spatial science revealed more about the language that its protagonists were talking in than the world that they were talking about. The most general outcome was a movement towards a process-oriented human geography that explored the process-domains of political economy and social theory, and then traced the marks made by these processes and practices on the surface of the Earth. At the time, several influential writers insisted that concepts of spatial science could not be adjudicated by appeals to the philosophy of science, but had to be articulated through the conduct of social practices: ‘The question “what is space?” is therefore replaced by the question “How is it that different human practices create and make use of distinctive conceptualizations of space?”’ (Harvey, 1973, p. 14). This introduced a relational concept in which space is ‘folded into’ social relations through practical activities. This allowed not only for the socialization of spatial analysis but also, crucially, for the spatialization of social analysis: like simultaneous equations, each was incomplete without the other (Gregory and Urry, 1985; Soja, 1989). The international journal Society and Space was founded in 1983 to foster the interdisciplinary conversations that were emerging in this new discursive arena.

Many of the first attempts to re-theorize ‘society and space’ were indebted to Harvey’s re-readings of Marx. Harvey argued that Marx’s critique of political economy implied a latent spatial structure that he never made explicit: capitalism as a system of commodity production also depends on the production of a space-economy, and its spasmodic crises in turn require a precarious ‘spatial fix’ (Harvey, 1999 [1982]). Others preferred to explore the writings of later Marxist scholars, notably Henri Lefebvre and his suggestive yet enigmatic account of the production of space (Lefebvre, 1991b). Harvey had always acknowledged his interest in Lefebvre, and subsequently integrated his own work with some of Lefebvre’s key propositions and, en route, diagrammed the implications of absolute, relative and relational spaces for a revitalized historical materialism (Harvey, 2006a; see also Gregory, 1994, pp. 348–416).

Later contributions pursued the spatial implications of other thinkers with varying degrees of success (Crang and Thrift, 2000). Two diagnostics have repeatedly emerged. The first is an unwavering concern with ontology: with grasping the significance of space not for the constitution and conduct of capitalism alone, but for being-in-the-world. Pickles (1985) was one of the first human
geographers to provide a rigorous account of the implications of existentialism and phenomenology for understanding human spatiality, and these themes have re-emerged in later thematizations of space (e.g. Strohmayer, 1998). The second is a persistent interest in concepts of space that are markedly less orderly than those of spatial science and its successor projects, sometimes through readings of outlaw Marxists such as Walter Benjamin (Latham, 1999; Dubow, 2004) and sometimes through post-structuralism: the most influential figures here have been Gilles Deleuze, Michel Foucault (Crampton and Elden, 2007) and Jacques Lacan.

Taken together, contemporary theorizations of space in human geography (and beyond) share the following features:

1. The integration of time and space. Conventional social science privileged the first term (so that time was seen as change, movement and history) while marginalizing the second (so that space was seen as the site of stasis and stability). Human geography has abandoned the project of an autonomous science of the spatial, rejected conceptions of space as the fixed and frozen ground on which events take place or processes leave their marks, and is now exploring the mobile, processual fields of ‘time–space’ (May and Thrift, 2001; see time-geography; time–space compression; time–space expansion).

2. The co-production of time and space. Time and space are not neutral, canonical grids that exist ‘on the outside’, enframing and containing life on Earth, but are instead folded into the ongoing flows and forms of the world in which we find ourselves. Thus Thrift (1996; see also 2008) introduces the idea of spatial formations to figure a sensuous ontology of practices and encounters between diverse, distributed bodies and things. This is a thoroughly materialist account, but it operates through an analytics of the surface rather than the ‘depth models’ of mainstream Marxism, and it refuses the oppositions between ‘culture’ and ‘nature’ on which historical materialism is predicated. Time–space emerges as a process of continual construction ‘through the agency of things encountering each other in more or less organized circulations’ (Thrift, 2003, p. 96). Similarly but differently, Rose (1999b) draws on feminist theory, and particularly the work of Judith Butler, to insist that space is not a pre-existent void or ‘a terrain to be spanned or constructed’: it is instead ‘a doing’, a performance.

3. The unruliness of time–space. Both spatial science and conventional social theory made too much of pattern and systematization, labouring to solve what they called ‘the problem of order’, without recognizing the multiple ways in which life on Earth evades and exceeds those orders. The sense of partial ordering and incompleteness is focal to many contemporary theorizations. To be sure, space is not infinitely plastic: ‘certain forms of space tend to recur, their repetition a sign of the power that saturates the spatial’ (Rose, 1999). And yet, while modalities of power often work to condense particular spatialities as ‘natural’ outcomes through architectures of surveillance and regulation, Massey (2005) insists that space is not a coherent system of discriminations and interconnections, a grid of ‘proper places’. She argues that space necessarily entails plurality and multiplicity. Hence spatial formations involve (and invite) ‘happenstance juxtapositions’ and ‘accidental separations’, so that time–space becomes a turbulent field of constellations and configurations: a world of structures and solidarities, disruptions and dislocations that provides for the emergence of genuine novelty. ‘Emergence’ is not necessarily progressive or emancipatory, of course, and the argument may also be put in reverse: contemporary spaces of exception (see exception, spaces of) trade on paradoxical orderings of space whose very ambiguity is used to foreclose possibilities for political action. Either way, however, far from space being ‘the dead’, as one of Foucault’s astringent critics once claimed, it is now theorized as being fully involved in the modalizations of tension and transformation.

4. The porosity of time–space. Constellations of power and knowledge are typically elaborated through a spatial system of inclusions and exclusions, most generally through the demarcation of a ‘space of the same’ from which ‘the Other’ is supposedly excluded (cf. imaginative geographies). A common critical response to these measures is to call these b/ordering processes to account — to
denaturalize them by disclosing their constructedness – and to break open (literally to de-limit) the ‘space of the Same’. This involves recognizing the presence of the Other within the space of the Same: the ways in which the geographical knowledges brought ‘home’ by European explorers relied on, appropriated and so smuggle in indigenous knowledges, for example, or the ways in which the racialized, gendered and ‘pure’ spaces of colonialism were routinely disrupted and transgressed (cf. hybridity; transculturation).

Thinking about time–space in these ways invites critical readings of the ways in which landscape, maps and other conceptual devices function as representations – as orderings – of space, redescribing their naturalization as the product of political technologies and cultural practices, and calling into question the discipline’s claims to know the world by rendering it as a transparent space (cf. situated knowledge). But they also require other ways of grasping time–space, and there are signs of experiments with the performing, plastic and media arts to subvert our taken-for-granted methods of representation, and to open new political spaces for observant participation in the making of human geographies.

space syntax An approach to studying the spatial structure of cities using mathematical tools to describe their complexity. For example, the street system may be analysed topologically by calculating the complexity distance for each street – that is, the minimum number of links needed (i.e. streets traversed) to reach all other streets in the city (see topology). The measures extend beyond three-dimensional descriptions of the elements of the built environment themselves to assessments of how they are integrated – as in the use of isovists to identify the area visible from any point, either at street level or, say, from a window on a building’s fourth floor. (In geographic information systems these are termed viewsheds.) Such representations, using maps and graphs as well as numerical indices, allow the city’s ‘navigability’ to be assessed – how easy is it to get around and to get from one point to another? – with techniques that can be applied at any scale (how easy is it to get around an airport terminal, for example?).

Using their syntactical representations of the urban built environment, workers at the Space Syntax Laboratory at the Bartlett School of Architecture, University College London have studied commuting and other movements, linking flows to the urban structure and thereby providing means for predicting future traffic patterns and transport system demands.

space-economy The idea that economic processes extend across geographical space, thereby influencing their operation and outcome. Walter Isard (1956) coined the term, using it as the basis for his new discipline of regional science. In his (much earlier) development of location theory, August Lösch (1954 [1940]) had already shown that economic competition in space does not have the same beneficial outcomes claimed in standard economic theory, because competition is monopolistic in spatially extensive markets (see neo-classical economics). Location theory and regional science developed a series of related claims showing how space makes a difference to economic theory, making the term popular in the 1950s and 1960s. Within this tradition, spatial structures, a consequence of rational economic decision-making, drive equilibrium outcomes and social welfare implications that differ from those of mainstream, a-spatial economic theory. Since 1990, with a revival of this tradition of work in geographical economics, the term has regained its popularity (Fujita, Krugman and Venables, 1999; see also new economic geography).

A parallel usage can be found within geographical interventions in Marxism and political economy, particularly among theorists whose intellectual socialization was influenced by spatial science and location theory, and who subsequently became highly critical of these formulations. Thus Harvey (1999 [1982]) used the term to describe how the geographical organization of capitalism shapes its dynamics and evolution, calling into question some core beliefs of the conventional a-spatial Marxist critique of capitalism, and Sheppard and Barnes (1990) took these arguments still further in their analysis of the capitalist space-economy. In this view, space
Spatial analysis

The application of quantitative methods in locational analysis within human geography and sometimes used as a synonym for that portion of the discipline that concentrates on the geometry of the landscape (cf. spatial science). O’Sullivan and Unwin (2002) present spatial analysis as the study of the arrangements of points, lines, areas and surfaces on a map, and of their interrelationships. Analyses of those separate components have deployed procedures adapted from other sciences – nearest-neighbour analysis and quadrat analysis, for point pattern analysis; graph theory for lines; and trend surface analysis for surfaces, for example. Whereas many geographers have undertaken analyses of the interrelationships using techniques from within the general linear model, others have argued that spatial analysis poses particular statistical problems because of the nature of spatial data (cf. spatial autocorrelation), thus requiring special techniques.

The development of geographic information systems is rapidly facilitating advances in spatial analysis and the greater power of computers, together with software developments, has significantly increased geographers’ ability to work with large and complex spatial data sets (cf. geocomputation).

Spatial autocorrelation

The presence of spatial pattern in a mapped variable due to geographical proximity. The most common form of spatial autocorrelation is where similar values for a variable (such as county income levels) tend to cluster together in adjacent observation-units or regions, so that on average across the map the values for neighbours are more similar than would occur if the allocation of values to observation-units were the result of a purely random mechanism. This is positive spatial autocorrelation. Negative autocorrelation is where neighbouring regions are significantly dissimilar; more general and complicated forms of autocorrelation can also be defined. The presence of spatial autocorrelation is very widespread and indeed may be said to lie at the core of geography, as expressed in Tobler’s (1970) — light-hearted — First Law of Geography: ‘everything is related to everything else, but near things are more related than distant things’.

However, the presence of spatial autocorrelation violates a basic assumption of independence in many standard statistical models. Thus for regression, there is an assumption that the residuals are not autocorrelated. The issue of spatial autocorrelation was recognized early in the history of inferential statistics, but it was not until the work of Moran and Geary in the late 1940s and 1950s.
that tests were devised, and it was the developments by Cliff and Ord that brought the topic to prominence. A mathematical representation of ‘neighbours’ was a stumbling-block to computing the tests, and Cliff and Ord reformulated Moran’s test to employ a $W$-matrix of size $N \times N$, where $N$ was the number of regions or observations, and a cell value $w_{ij}$ of 1 indicated that regions $i$ and $j$ were neighbours, and 0 if they were not (Cliff and Ord, 1973). This idea opened up a whole field of research, and spatial autocorrelation is now a theme in many social sciences. Moreover, as Tobler’s Law suggests, spatial autocorrelation should not just be seen as a problem but also as a reflection of spatial interaction and a central aspect of spatial modelling, and this has been the basis for the development of spatial econometrics. The Moran test is a global one, detecting whether there is autocorrelation on average across the set of regions; a more recent development has been the disaggregation of this measure into local measures, such as Anselin’s LISA (Local Indicators of Spatial Association) to detect local clusters of positive and negative autocorrelation (Anselin, 1995). (See also LOCAL STATISTICS.)

spatial econometrics An interdisciplinary research field being developed by economists, geographers and statisticians. The term was invented by Jean Paelinck (Paelinck and Klaassen, 1979), and the research focuses on the construction and application of statistical models and tests explicitly designed for spatial (geographical) data, building on initial work on spatial autocorrelation by Cliff, Ord and others.

The field of econometrics was developed throughout the twentieth century by economists to deal with the special statistical modelling issue posed by the non-experimental context of economics and the social sciences, often very different from the laboratory and agricultural field-trials context for which much statistical theory was developed. In particular, econometricians constructed methods to deal with time-series autocorrelation, time-lags and dynamics in economic relationships and simultaneity and feedback between different equations in macroeconomic models. However, it is only in recent decades that equivalent techniques for spatial data have been developed. Amongst many contributors, Luc Anselin’s work, and his computer package SpaceStat, have been particularly influential in developing both the methods and their application. The focus of the field has moved from testing for spatial autocorrelation towards the modelling of spatial interaction through spatial diffusion, spatial lags or spillovers, and endogeneity is a major focus in the construction of the estimators and tests.

spatial fetishism Any approach that treats space as sufficiently autonomous to social processes that ‘no change in the social process or spatial relations could alter the fundamental structure of space’ (Smith, 1981b, p. 112). The term was developed in the course of interactions between human geography and Marxism; by analogy with Marx’s critique of commodity fetishism, in which the conditions of production of a commodity are made invisible and the economy is reduced to exchanges between objects rather than seen as a series of unfolding social relations and practices, so it was argued that approaches such as spatial science conceptualized space as somehow exogenous to and separate from social processes (cf. Soja, 1980) (See also SPATIAL SEPARATISM.)

spatial identity The ways in which identities are constituted, articulated and contested in relation to space and place. A wide range of research has explored the territorialized spatialities of identity in relation to, for example, a region, ‘homeland’ or nation. Other research traces the deterritorialized – and reterritorialized – spatialities of identity in terms of migration, diaspora and borderlands. Whilst some research has viewed space merely as a container for identity, or as a stage on which identities are played out, other research – particularly since the 1990s – traces the mutual constitution of both space and identity and their multiple and contested articulations (including Keith and Pile, 1993). Rather than view spatial identities in essentialist terms, this research – often inspired by post-structuralism, psychoanalysis and post-colonialism – traces their politicized differentiation. Although spatial metaphors have been particularly important in conceptualizing identity, geographers have been concerned to ground and locate the material spatialities of identity, which are often closely bound up with ideas about situated
knowledge, the politics of location, and the spatial politics of identity (Yaeger, 1996; see also Positionality). In a wide variety of contexts, geographical analyses of spatial identity thereby explore the metaphorical and material relationships between space, identity and power.

Post-colonial and feminist theorists have been particularly influential in theorizing spatial identity. In his classic work, Orientalism, Edward Said (2003 [1978]) explored the imaginative geographies of ‘self’ and ‘other’ through the intensely politicized spaces of the ‘Orient’. Other post-colonial theorists have explored the spatial identities bound up with migration, diaspora and the contested politics of hybridity, multiculturalism and cosmopolitanism (including Hall, 1996a). In feminist theory, a frequently cited essay by Minnie Bruce Pratt (1984) traces her sense of identity through multiple spaces of home and memory. Other feminist theorists have theorized the interplay of gender and other identities in place, over space, and in shaping the production of space and knowledge. In her analysis of ‘locational feminism’, for example, Susan Stanford Friedman (1998) explores the critical interplay of space and identity through different discourses of positionality. As part of these discourses, ‘situational approaches’ not only ‘assume that identity resists fixity, but they particularly stress how it shifts fluidly from setting to setting’, whereby ‘[e]ach situation presumes a certain setting as site for the interplay of different axes of power and powerlessness’ (p. 23).

Spatial mismatch The notion that constraints on residential choice prevent members of certain groups from adequate access to employment (also referred to as the spatial mismatch hypothesis). Urban economist John Kain first used the term in the 1960s to describe the impacts of residential segregation and housing market discrimination on the employment opportunities and earnings of black residents of Chicago and Detroit (Kain, 1968). In a retrospective published after his death (Kain, 2004), Kain noted that he later extended the concept to include other negative impacts, such as those on home ownership and quality of education, and of discrimination in the housing market.

Following Kain’s early lead, most research on spatial mismatch has sought to understand the extent to which the black–white disparity in earnings can be explained by blacks’ inferior spatial accessibility to employment. As employment, and particularly manufacturing employment, increasingly suburbanized after the Second World War, access to such employment depended on a suburban residential location; but a variety of discriminatory practices in the housing market prevented blacks from moving to the suburbs. As a result, blacks were confined to inner-city neighbourhoods, which were increasingly bereft of manufacturing jobs.

Until recently, research on spatial mismatch concentrated on comparing the residential and employment patterns and commuting times of black and white men; McLafferty and Preston (1997) and others have shown the importance of expanding such studies to other racialized groups such as Latinos/Latinas, and to women.

Evidence supporting the spatial mismatch hypothesis was one factor that led the US Department of Housing and Urban Development (HUD) to initiate an experimental programme, ‘Moving to Opportunity’, to help low-income people from high-poverty neighbourhoods to move to racially integrated, low-poverty suburban locations. Subsequent studies have evaluated the extent to which such residential mobility and the resulting

spatial monopoly Monopolistic control over a market by virtue of location. The usual meaning of MONOPOLY is that one firm or individual sells the entire output of some commodity or service. This is normally the final outcome of a competitive process taking place under capitalist market conditions, in which one supplier is able to produce and sell the commodity at a price favourable enough to consumers to force other suppliers out of business. Spatial monopoly is a special case, in which distance from competitors or ways of bounding space give a producer monopolistic control over a section of the market.

Spatial monopoly can arise when a producer is distributing a commodity from its point of origin, and also when consumers travel to the point of origin. In the first case, the operation of an f.o.b. pricing policy, whereby the cost of transportation is passed on to the consumer (see PRICING POLICIES), will increase delivered price with distance from the production point, so that consumers close to the production point can purchase the commodity relatively cheaply; that is, more cheaply than from alternative suppliers. The greater the elasticity of demand, or the sensitivity of the consumer to price, the greater the likelihood of local monopoly. The area within which monopoly control exists (assuming that consumers buy from the cheapest source) is bounded by a locus of points where delivered price from the supplier in question is equal to the price charged by a competitor. In the second case, consumers will tend to travel to the production point which is closest in time, effort or cost. In this case, too, the area of monopoly control will be bounded by a locus of points of consumer indifference as to whether to purchase from one point to another.

Spatial monopoly can also arise from collusion between otherwise competing firms, who may agree to a ‘carve-up’ of the market among themselves. As in other situations of spatial monopoly, this will enable suppliers to raise prices and exact above-normal profits in the area over which they exert exclusive control. Distance provides no absolute protection of a market, however, for some consumers may choose to purchase from high-cost sources or to travel to more distant outlets, out of preference, ignorance or other behavioural considerations.

There may be other strategies for protecting space over which monopoly control is exerted. These include the imposition of tariffs and restriction on the use of means of transportation: suppliers may use coercion to prevent competitors from entering a particular city to sell their goods, for example, as has happened in the former Soviet Union since the collapse of SOCIALISM.

In some instances, spatial monopoly may be a case of so-called natural monopoly, where the market in question is best served by a single firm because of the nature of the production process. Some public utilities are of this kind; for example, local water supply. Such public spatial monopoly may be turned into private monopoly by PRIVATIZATION.

spatial science The theoretical approach associated with the QUANTITATIVE REVOLUTION in Anglo-American GEOGRAPHY in the 1960s that privileged spatial analysis. During this period many human geographers turned from the integrated, descriptive and IDIOGRAPHIC analysis of specific places (i.e. the traditional forms of REGIONAL GEOGRAPHY) to the specialized, theoretically inflected and NOMOTHETIC analysis of SPATIAL STRUCTURES; that is, spatial science. EPISTEMOLOGICALLY, this stream of work, the so-called 'New Geography' of the 1960s, is usually associated with the PHILOSOPHIES OF LOGICAL EMPIRICISM and LOGICAL POSITIVISM, the prevailing norms in the natural sciences and the emergent best practice in other social sciences after 1945. By aligning itself with 'normal science', and in another sense with ‘extraordinary research’ and ‘scientific revolutions’ (see PARADIGM), geography successfully sought to enhance its academic status (Ad Hoc Committee on Geography, 1965; see also Billinge, Gregory and Martin, 1984b). While rarely describing itself explicitly as positivist, it was presumed that reliable EXPLANATIONS could be achieved by constructing universal deductive causal explanations whose accuracy could be
assessed by reference to independently gathered observations (Harvey, 1969).

In HUMAN GEOGRAPHY, this approach was used to develop theories of the location of human activities, the Spatial Interactions between places and the spatial Diffusion of phenomena from one place to another. Typically, research proceeded by constructing mathematical–statistical Models and then comparing them to observations using spatial analysis (spatial statistics and Monte Carlo Simulation). While some spatial science suffers from Spatial Fetishism and Spatial Separatism, these are by no means inherent shortcomings. Both the Social Construction of space and the Theory-laden nature of observations were recognized within spatial science.

Given this history, it is ironic that the term ‘spatial science’ first appeared in English in Hartshorne’s programmatic statement of The nature of geography (1939). This text was the bête noire of Spatial Science: Hartshorne discussed Location theory en passant but ruled it out of geographical enquiry, and he located geography alongside what he called other ‘spatial sciences’, such as astronomy (cf. Cosmography), only to insist that the intrinsic Exceptionalism of geography necessarily relocated it with the idiographic sensibilities of history rather than the theoretical and statistical modalities of the other, normal sciences. When the term ‘spatial science’ reappeared, it was not part of the rival prospectus of the quantitative revolutionaries at all but, rather, named their research as the object of critique: thus the second chapter of Gregory’s Ideology, science and human geography (1978a) was entitled ‘In place of spatial science’.

Since then, spatial science has become a catch-all characterization of forms of spatial analysis and theorization associated with the Quantitative Revolution and its derivatives. At its most general, it describes a divide within human geography and also between human and Physical Geography that separates those who see themselves as following the prescriptions of natural science from those who do not. Since the 1990s, as GIS has reinvigorated spatial analysis and as cognate social sciences such as economics, with stronger allegiances to the epistemologies of natural science, have rediscovered geography (see NEW ECONOMIC GEOGRAPHY), spatial science has gained new adherents. Yet the divide is based on the supposition that natural science entails different norms than the human sciences – a claim that has been increasingly questioned in contemporary geography, Philosophy and the philosophy of Science and Science Studies (cf. Harrison and Dunham, 1998; Massey, 1999).

**Spatial Separatism** Any geographical theory asserting that physical space is an independent cause of human behaviour. Separatism has two meanings here: separating space from social processes, and separating Human Geography from other social sciences. The term was coined by Sack (1973, 1974b) to criticize claims made specifically by Bunge (1966, 1973) in his prospectus for theoretical geography that geographical theories explain using geometric laws, thereby giving geography an exceptional status relative to the laws of other social sciences. Sack, like critics of Spatial Fetishism, argued that space is relational – an emergent outcome of social processes – and that this made such separatism untenable.

**Suggested reading**

**Spatial Structure** The organization of social and biophysical phenomena in space. The term was coined within Spatial Science to refer to the spatial coherence, geometric order or systematic spatial pattern (particularly spatial equilibria) generated by human activities. It implied an order in geometrical–mathematical–statistical domains characterized by degrees of symmetry, regularity and predictability. The term was subsequently used in a less restrictive, less formalist sense in Human Geography and in Social Theory to refer to the interdependence of human agency and spatial structures, whereby agency responds to but also reproduces and transforms its spatial templates (cf. Gregory and Urry, 1985). The term is now used more eclectically still, to refer to any more or less ordered spatial arrangement, Assemblage or system: the orderings through which space is implicated in the operation and outcome of social and biophysical processes. The emphasis on ‘ordering’ rather than ‘order’ directs attention to the ‘folding’ of Time and Space into the operation of processes in contingent, fluid and sensuous ways. This recognizes that practices and performances evade and exceed the symmetrical and/or logical orders proposed by classical social theory (hence its ‘problem of order’) and by neo-classical spatial science, and requires ‘order’ or ‘structure’ to be treated as a Process rather than a thing.

**Spatiality** The mode(s) in which space is implicated in the constitution and conduct of
life on Earth. There are four main senses in which ‘spatiality’ has been used in human geography and allied fields, but these increasingly interrupt and braid into one another:

(1) Drawing upon existentialism and phenomenology, and in particular the writings of European philosophers Martin Heidegger (1889–1976) and Edmund Husserl (1859–1938), Pickles (1985) proposed human spatiality as the fundamental basis on which ‘geographical inquiry as a human science of the world can be explicitly founded’. Pickles’ primary concern was ontology: with understanding ‘the universal structures characteristic of [human] spatiality as the precondition for any understanding of places and spaces as such.’ Pickles objected to those views that regard the physical spaces of the physical sciences as ‘the sole genuine space’. This sort of thinking was typical of spatial science but, in Pickles’ view, was wholly inappropriate for a genuinely human geography. He urged in its place a recovery of our ‘original experiences prior to their theorization by any scientific activity’; that is, a rigorous exposure of the taken-for-granted world assumed but left unexplained by spatial science. One of its essential characteristics is what Pickles called ‘the structural unity of the “in-order-to”’. Our most immediate experiences are not cognitive abstractions of separate objects, Pickles argued, but rather ‘constellations of relations and meaning’ that we encounter in our everyday activities — what Heidegger called ‘equipment’ — and which are ‘ready-to-hand’. Such a perspective reveals the human significance of contextuality. For human spatiality is related ‘to several concurrent and non-concurrent equipmental contexts’ and ‘cannot be understood independently of the beings that organise it.’ Spatiality thus has the character of a ‘situating’ enterprise in which we ‘make room’ for and ‘give space’ to congeries of equipment. Put in this way, there are distant echoes of time-geography, but Pickles is evoking an intellectual tradition antithetical to the physicalism of Torsten Hågerstrand’s early writings and which fastens not on ‘objective space’ but on a fully human, social space (see also Schatzki, 1991).

(2) Drawing upon structural Marxism of the 1960s and 1970s, a number of Francophone sociologists and economists suggested that concepts of spatiality be constructed to identify the connections and correspondences between social structures (modes of production) and spatial structures. French philosopher Louis Althusser (1918–90) had argued that different concepts of time or temporalities could be assigned to different levels of modes of production — ‘economic time’, ‘political time’, ‘ideological time’ — and that these had to be constructed out of the concepts of the different social practices within these domains. In much the same way, it was argued that different concepts of space or spatialities could be assigned to different levels of modes of production. Castells (1977) presented the most detailed analysis of capitalism in these terms, but insisted that it made more sense to theorize temporality and spatiality together and to speak of distinctive space-times (see Gregory 1994, pp. 94–5).

(3) Drawing upon the broadly humanist Marxism of Henri Lefebvre (1901–91) and his account of the production of space, Soja (1985) used the term spatiality ‘to refer specifically to socially produced space, the created forms and relations of a broadly defined human geography’. ‘All space is not socially produced,’ Soja continued, ‘but all spatiality is’. In the course of his work as a whole, Lefebvre provided critiques of existentialism and phenomenology and of structuralism and structural Marxism, and so Soja insists that his ‘materialist interpretation of spatiality’ cannot be assimilated to either of the two traditions summarized above. For to speak of ‘the production of space’ in the spirit of Lefebvre is to accentuate spatiality as ‘both the medium and the outcome’ of situated human agency and systems of social practices in a way that, so Soja argued, was broadly consonant with structuration theory. Transcending his earlier claims for a ‘socio-spatial dialectic’ (Soja, 1980), Soja (1985) now concluded that ‘spatiality is society, not as its definitional or logical equivalent, but as its concretisation, its formative constitution.’ And it is precisely this realization, so he subsequently argued, that was characteristic of postmodernism.
and its reassertion of space – of spatiality – in critical social thought (Soja, 1989: see also THIRD SPACE; TRIALECTICS). Other human geographers working under the sign of a critical Marxism equally cognizant of Lefebvre have also conceptualized spatiality as socially produced space, and while they rarely endorse Soja’s celebration of postmodernism they do accept that space is not a mere reflection of but is rather constitutive of capitalism as a dialectical totality (see, e.g., Sheppard, 2004; Harvey, 2006a). More than this, many of them now recognize that this implication of a produced space must incorporate non-human agency too: ‘the manifold biophysical processes and technologies that shape the spatiality of the world’ (Leitner, Sheppard and Sziarto, 2008, p. 158).

Drawing upon POST-STRUCTURALISM – in particular, the work of Michel Foucault (1926–84) and of Gilles Deleuze (1925–95) and Félix Guattari (1930–92), together with the post-phenomenology of Alphonso Lingis (1933–) and others – a number of writers use spatiality to indicate the ways in which mobile constellations of power-knowledge and subject positions are constituted through the production and performance of space as an ‘ordering’ rather than a fixed and closed order (cf. Thrift, 2007, p. 55). Accordingly, they attempt to grasp space as an ‘immanent spatiality’, through which the world is registered as a ‘multi-linear complex’ whose contingent intersections and folds constantly open and present – which is to say make present – the emergence of ‘the new’ (Dewsbury and Thrift, 2005). These developing conceptions of spatiality, like those in the preceding paragraphs, have important implications for a GEOGRAPHICAL IMAGINATION that is also a profoundly material imagination (Anderson and Wylie, 2008) (see also NON-REPRESENTATIONAL THEORY).

These four traditions cannot be assimilated to any grand synthesis, but many writers share a subterranean dialogue with figures such as Marx, Heidegger and Foucault, and there is increasing traffic between their conceptions of spatiality: for example, Sheppard’s (2008) exploration of DIALECTICAL totalities and ASSEMBLAGES. For all the differences between them, all four traditions reject the conventional separations between ‘society’ and ‘space’ (which can be traced to a persistent KANTIANISM) and in this sense can be read as four moments in the movement towards an exploration of what Smith (1990) called ‘deep space’: that is to say, ‘quintessentially social space . . . physical extent fused through with social intent’.

spectacle A term that often refers to a large-scale cultural event, festival or celebration, or to an urban scene or stage set presented for visual consumption. It has been prominent in analyses of the significance of IMAGE production and the management of appearance in strategies of urban development in recent decades, with attention focusing in particular on temporary cultural events such as carnivals, International Expositions and sporting events, including the Olympic Games (Gold and Gold, 2005), as well as on more permanent spaces of entertainment, ‘theme park urbanism’ and ‘cities of spectacle’. The use of spectacular events has a long history, from the ‘bread and circuses’ of ancient times to efforts to promote European medieval city-states and metropolises of the nineteenth century. Yet the production of spectacles has become a common part of cultural strategies of economic development more recently, with studies exploring their implications for capital investment, cultural identity and TOURISM, and drawing out their multiple and contested readings by audiences. Many critics argue that such spectacles serve a diversionary function, masking underlying social and economic inequalities.

A key reference in critical discussions is Guy Debord’s book The society of the spectacle, first published in 1967. This is concerned less with spectacles as cultural events than with the spectacle in a critique of an alienated and image-saturated world. Developing earlier Marxist critiques of COMMODITY fetishism and ALIENATION, Debord writes that the spectacle ‘corresponds to the historical moment at which the commodity completes its colonization of social life’ (1994 [1967], thesis 42). This new stage in the ACCUMULATION of capital and the domination of social life by the ECONOMY is not simply the result of mass media manipulation and visual technologies, he stresses, for ‘the spectacle is not a collection of images; rather it is a social relationship
between people that is mediated by images’ (thesis 29). Urbanism takes on particular importance within the spectacle as a technique for reshaping space and ensuring the separation between people, although it is also a terrain within which struggles against the spectacle and for different relationships between people are forged.

As developed by Debord and the Situationists, the concept of the spectacle was part of a revolutionary project and was meant to be a weapon with which to harm spectacular society. This has not prevented it from being widely adopted within cultural, media and urban studies seeking to characterize a new cultural and mediatized era, and becoming ‘a stock phrase in a wide range of critical and not-so-critical discourses’ (Crary, 1989, p. 97). Yet emphasizing its original analytical force, the group Retort (2005) insists that Debord’s account speaks powerfully to a current ‘new age of war’, in which struggles over images and the capitalist state’s concern with the rule of appearances are of vital political significance.

**spontaneous settlement** A residential area developed outside the formal economy by its inhabitants, often after illegally occupying the land, and usually found in developing countries. Both the housing and infrastructure of public facilities are constructed outside the usual market and public service mechanisms. Although the term ‘spontaneous’ suggests no forethought or planning, many such clandestine settlements are the result of ‘planned invasions’ by the initial occupants, who subdivide the land on a pre-arranged cadastre and provide a basic infrastructure (cf. squatting).

**sport(s)** Human geography has paid increased attention to sports partly as a result of the increased economic and cultural importance given to issues of leisure and recreation, but most especially because insights from cultural theory have been brought to bear on the performance of sports. Studies commonly take one of five approaches:

1. The plotting of the economic connections and organizations of sports. This follows the fortunes of ‘mega-events’ such as the Olympics or soccer World Cup, and their linkage to patterns of urban development, or the competition over sport club franchises and stadia location.
2. The diffusion and location of different sports across the globe. This tracks the relative popularity and adoption of different games, often as a cultural form in Berkeley school approaches to cultural geography.
3. The development and often hybridization of these sports in a colonial and post-colonial world (see Colonialism; Hybridity; Post-colonialism). They become examples of contestation of meaning and adoption of cultural practices. Thus the imposition of cricket ovals across South Asia, its enthusiastic adoption and the transport of the game to the West Indies are used by C.L.R. James in his *Beyond a boundary* to suggest that it offers both insights into colonizing cultures and a stylization of resistance to that process. The postwar adoption of baseball in Japan also offers moments of cultural contact, understanding and transformation.
4. A historical geography of the emergence and role of sports in varying social milieu. The rise of organized mass spectator sports alongside industrialization, complementing or even replacing other modes of regulation, is important here, as is the construction of progressively more homogenized fields, arenas and venues as forms of abstract space. The rapid mediatization of team sport and the culture of viewing has been related to the society of the spectacle, where a telespatial temporality and dramatization is now driving sport.
5. The emergence on and off the pitch of techniques of the body that form exemplars of disciplinary power and the mobilization and channelling of collective affect to create an emotional geography of support, loyalty, joy and suffering. The surging crowd at a game, or indeed around a large screen, enact changing performances of emotionality, race and gender. Alternatively, the body cultures in recreations and outdoor sports offer new ways to think about people’s modes of engagement with landscape.

sprawl  Dispersed, low-density development on the edges of urban areas, characterized by fragmented and ribbon development. It is often associated with edge cities and with bland, car-oriented and functionally segregated landscapes. While sprawl is often associated with a lack of planning, others suggest that government policies and public agencies, influencing decisions about road construction, housing financing and zoning, for instance, have shaped the rise of sprawling cities (e.g. Wolch, Pastor and Dreier, 2004). ‘Sprawl’ is also a highly political word, framing debate over the loss of agricultural land and wildlife habitat, the costs of automobile use, and appropriate design and policy solutions (Duany, Plater-Zyberk and Speck, 2000). EM

squatt ing  Dwelling in a home built on land that does not belong to the builder, typically without the consent of the land owner, in the absence of formal planning and regulation. In many countries in the world, a significant proportion of the population lives in squatter housing; for instance, this is the case for roughly half of the residents in Istanbul or Delhi. Squatter housing is typically built quickly to establish a de facto claim, and basic infrastructure for water, drainage, sanitation, electricity and roads is at first missing. Squatter settlements are often built on state-owned land, located on the periphery of an urban area (though relative centrality can change as cities grow up to and around them), or on unproductive land such as swamps, saline flats or steep hillsides. Although squatter housing exists outside private property relations, it can be commodified and traded (see commodity; market): over one-third of squatter housing in Turkey is rented, and in Hong Kong in the 1960s and 1970s the secondary housing market in squatter dwellings bore a striking resemblance to the parallel legal real estate market (Smart, 1986). Although most of the world’s squatting occurs in the cities of the global south, there have been squatters’ movements in European and North American cities, particularly in the 1970s and 1980s; at moments of housing shortage, squatters occupied vacant buildings without the consent of owners, to gain access to affordable housing and often as a critique of private property relations and urban restructuring (Pruijt, 2003: see also homelessness; slum).

In the late 1960s, academics studying the global South began to reassess the earlier view that squatter settlements were a ‘cancer on the carapace of the city’ (quoted in Gonzalez de la Rocha, Perlman, Safa, Jelin, Roberts and Ward, 2004) or evidence of dysfunctional urbanism. Studying settlements that had ‘consolidated’ over time, they stressed the existence of social networks in squatter communities and began to conceive of them as rational and viable responses to rapid urbanism, as a solution to rather than a problem of massive rural to urban migration. This view continues to inform Hernando De Soto’s (1989) influential celebration of the entrepreneurialism and capacity for self-organization within squatter communities (now taken up by the World Bank). De Soto recommends that property ownership be extended to squatters to facilitate their capacity to petition the state for more services and to use their property as collateral to obtain loans, which then can be used to improve their property or invest in small businesses.

A critical literature has arisen to argue, first, that consolidation and stabilization of squatter communities can happen in the absence of private property ownership (Varley, 2002) and, second, that there are serious limits to addressing issues of poverty and social marginalization through land titling and upgrades to housing and urban infrastructure (Roy, 2005). Extending private property ownership can lead to gentrification and displacement, and the consolidation of patriarchal power relations (given that land title is typically granted to the male household head), and there is little evidence that land title opens access to credit or alters employment conditions (Gonzalez de la Rocha, Perlman, Safa, Jelin, Roberts and Ward, 2004; Roy, 2005). Among scholars from Latin America, there is less optimism now about the prospects for those living in squatter settlements. The structural adjustment and austerity policies of the 1980s followed by the neo-liberal restructuring (see neo-liberalism) of the 1990s led to rising unemployment, declining opportunities in informal sectors, the devolution of the delivery of social goods to non-governmental organizations (see NGO), and increasing – often drug-related – violence. Perlman notes of Rio de Janeiro, ‘After many decades of co-existence, Rio’s populous has again begun to fear and shun the favelas due to a sharp increase in violence. Although the favelados [residents of squatter communities] themselves are no longer considered marginal,
the physical territory of their communities has become tightly controlled by the drug dealers, who ... are known locally as “the marginality” or “the movement”’ (Gonzalez de la Rocha, Perlman, Safa, Jelin, Roberts and Ward, 2004, pp. 189–90). In other contexts, there is more optimism about the potential for squatter mobilization (Appadurai, 2001).

**stages of growth** The notion that societies, polities or entire civilizations pass through stages or phases in their development, growth or maturation has a long intellectual lineage, and has been associated with very different forms of theorizing. Within certain forms of Marxism, history as the succession of modes of production or the need to pass through particular stages of economic organization has a long pedigree (Cohen, 1978). From a very different vantage point, the theories of Arnold Toynbee (1889–1975) and Joseph Spengler (1912–91) also contained strong senses of historical progression through epochs or stages. Within twentieth-century sociology it was modernization theory that exemplified the clearest instance of the suturing of evolution, teleology and economic history as a predetermined progression through stages of social, economic and political transformation along a path blazed by capitalist powers in Western Europe. It was from within this body of work that the notion of modernization as the culmination of a succession of stages out of backwardness received its fullest elaboration, and will be forever associated with the ideas of W.W. Rostow (1916–2003) and his foundational text The stages of economic growth: a non-communist manifesto, first published in 1960 (see Rostow, 1971). Like other modernization theorists, Rostow believed that the world was constituted by a fundamental rift between ‘traditional’ societies – supposedly mired in anti- or non-market mentalities, limited markets, pre-Newtonian science and a belief structure antithetical to self-sustaining growth – and modern societies that emerged in their modal form in seventeenth- and eighteenth-century Europe (see modernity). Rostow drafted his book against a backdrop of McCarthyism, a deep ideological and political cold war between East and West, and a massive effort by the USA to export development through USAID and other foreign aid channels to an increasingly insurgent Third World, led by a raft of African and Asian post-colonial (or about to become post-colonial) states (see decolonization).

In Rostow’s iteration – a model explicitly presented, as Rostow’s subtitle indicates, as an alternative to the idea of socialist modernization and the account of development set out by Marx and Engels in The communist manifesto (see historical materialism) – modern history was the transformation of tradition via a five-stage programme, through which all societies were to pass. The first of the five stages - the traditional society - is characterized by ‘primitive’ technology, hierarchical social structures (the precise nature of which is not specified) and behaviour conditioned more by custom and ascription rather than by what Rostow takes to be ‘rational’ criteria. These characteristics combine to place a ceiling on production possibilities. Outside stimuli to change (including, for example, colonialism and the expansion of capitalism) are admitted in the transitional second stage – the preconditions for take-off. Here, a rise in the rate of productive investment, the provision of social and economic infrastructure, the emergence of a new, economically based elite and an effective centralized national state are indispensable to what is to follow. In short, the opportunities for profitable investment presented by the preconditions for take-off are unlikely to be ignored by capital and they pave the way for the third stage: ‘takeoff into sustained growth. Rostow describes this stage as ‘the great watershed in the life of modern societies’. It is a period of around 10–30 years during which growth dominates society, the economy and the political agenda (although the social relations which facilitate this dominance are not described) and investment rises, especially in the leading sectors of manufacturing industry. Self-sustaining growth results in the fourth stage, ‘drive to maturity’, which is characterized by diversification as most sectors grow, imports fall and productive investment ranges between 10 and 20 per cent of national income. The increasing importance of consumer goods and services and the rise of the welfare state indicate that the final stage, the ‘age of high mass consumption’, has been reached (see also post-industrial society).

In some respects, the determinism of Rostow’s model was not too different from some of the worst excesses of structural Marxist political economy. Whether it
It is teleological in the sense that the end result (stage 5) is known at the outset (stage 1) and derived from the historical geography of 'developed' societies, which then form the template for the 'underdeveloped', which are thereby denied an historical geography of their own.

- It is mechanical in that, despite the claim that the stages have an inner logic 'rooted in a dynamic theory of production', the underlying motor of change is not explained, so that as a result the stages become little more than a classificatory system based on data for fifteen countries only, plus outline data for others.

- It is a-historical in that notions of path-dependency are ignored, so that it can be assumed that the historical geographies of the underdeveloped countries are unaffected by that of the dependent, and so the intervention of the latter into the former is simply an irrelevance – this position is also profoundly a-geographical, as it is incapable of recognizing that geographical relationships are continuously formed and re-formed across the world.

- It is ethnocentric in espousing a future for the world based on American history and aspiring to American norms of high mass consumption (see ethnocentrism).

Capitalist society is, following Rostow's logic, a necessary consequence of development. By concealing the social production of the stages, capitalist societies may be reproduced and extended by apparently neutral policies advocating apparently universal processes of growth. History, in other words, is serial repetition (in the argot of the present: 'there is no alternative'). In the context of the 1950s and 1960s, the non-communist manifesto was nothing short of an ideology for American empire.

Rostow saw his academic work as part of a political mission, and under Presidents Kennedy and Johnson he held positions with authority over US policy towards the Third World (see Menzel, 2006). He was a brilliant student – a Rhodes scholar in the 1930s – and he gravitated towards imperial trade policy, serving briefly, after a period on the Office of Strategic Services during the Second World War, as a professor of American History at Oxford. He returned to the USA in 1947, served as an assistant to Gunnar Myrdal at the United Nations and at the tender age of 33 was appointed to the chair of Economic History at MIT. It was here, during the Korean War, that Rostow and a group of other cold warriors developed a strategy for the economic containment of communism. Key to this strategy, which emerged more fully in the 1960s, was the sense that containment was to be achieved within the 'emerging nations' of the Third World, that external foreign assistance was key to shift poor nations from stages 2 to 3 (the alternative was the fostering of preconditions conducive to communism), an alliance with robustly anti-communist modernizing elites, and a strong state enhanced by a large military budget to push forward the long march through the stages to self-sustaining capitalist growth. Of course, it all went horribly wrong. The hubris of power was radically compromised in Vietnam (in which Rostow served a bleak and hawk-like function under President Johnson: Milne (2008) refers to him as 'America's Rasputin'), in the collapse of the Alliance for Progress in Latin America and in the ‘blowback’ from supporting various dictators and psychopaths, from Mubutu to Marcos. While Rostow’s career was blemished by Vietnam, it is perhaps true that his concern with the political preconditions for take-off – now the term of art is ‘governance’ – is more relevant than ever.

staples theory The theory that national and regional economic and social development is based upon the export of unprocessed or semi-processed primary resources (‘staples’). Although the theory has historical antecedents, and different (frequently truncated) versions of it have been presented (e.g. economic base theory), staples theory is most
closely associated with the work of the Canadian economic historian Harold A. Innis (1894–1952). In Innis’ account, and the basis for the school of Canadian political economy, staples production creates economic instability and hinterland dependency for staples-producing regions. At least three causes are at work:

(1) Markets for staple commodities approximate more closely perfect competition than do those for manufactured goods. Staples regions are price-takers in markets where unpredictability is the norm, producing cycles of boom and bust.

(2) For a variety of reasons (technological innovations that reduce resource inputs for production, the growth of synthetic substitutes, and low long-run income elasticities of demand), the terms of trade for primary commodities are increasingly less favourable to staples-producing areas.

(3) Resource extraction or production tends to be undertaken by large, often foreign-owned, transnational corporations. Spry (1981) argues that this is a direct consequence of the large capital expenditures and production indivisibilities associated with staples. The presence of such firms in staples regions creates a number of potential problems for the region including: the appropriation of economic rents because of the undervaluing of resources by the local state in order to induce investment; the failure to process the staple prior to export (and where value-added occurs) because resource extraction is only one stage within a vertically integrated corporation that for reasons of internal control locates manufacture elsewhere; the low levels of technological innovation and development; the lack of local control; and finally, a weakened ability to control trade through explicit policy because of the high degree of intra-corporate transfers.

For Innis, there is thus a direct relationship between the type of trade in which a staples region engages and its level of social and economic development. This contradicts the orthodox neo-classical theory of trade (see neo-classical economics), which would maintain that a staples nation such as Canada benefits from specializing in and exchanging those commodities in which it possesses a comparative advantage, namely primary resources. But in drawing upon this theory, as Innis (1956 [1929], p. 3) wrote in the late 1920s, economists ‘attempt to fit their analysis of new economic facts into . . . the economic theory of old countries . . . The handicaps of this process are obvious, and there is evidence to show that [this is] . . . a new form of exploitation with dangerous consequences.’

To circumscribe such exploitation, Innis developed his theory in such a way that it was peculiarly suited to the economic facts of staples regions. He brought together three types of concerns: geographical/ecological, institutional and technological (Barnes, 1996, ch. 8). Innis argued that when the right technology came together with the right geography and the right institutional structure, the result was accumulation of ‘cyclonic’ frenzy. In this way, virgin resource regions were transformed and enveloped within the produced spaces of the capitalist periphery. Such intense accumulation, however, never lasts, and because of the very instabilities of staples production, sooner rather than later investment shifts to yet other staples regions, leaving in its wake abandoned resource sites and communities. As countries such as China and India rapidly industrialize, drawing in immense flows of staples commodities, transforming regions and creating shudders across the world’s resource sites, Innis’ theory has never been more relevant (Hayter, Barnes and Bradshaw, 2003).

Barnes (1996, ch. 8); Drache (1995).

State A centralized set of institutions facilitating coercive power and governing capabilities over a defined territory. No one definition of the state is adequate given the way that states have varied in their form and function over time and space. However, Michael Mann (1984a) has identified the definitional need to incorporate both institutional and functional concerns, or what the state looks like and what it does. His subsequent definition can be summarized as follows:

(1) a set of institutions and their related personnel;
(2) a degree of centrality, with political decisions emanating from this centre point;
(3) a defined boundary that demarcates the territorial limits of the state; and
(4) a monopoly of coercive power and law-making ability (Jones, Jones and Woods, 2004, p. 20).
These four points must be complemented by understanding that the state is defined in relation to two other spheres of modern life, the market (or economic activity) and civil society. The functions of the state reflect the need to facilitate economic growth that generates the tax base to support a state apparatus (Tilly, 1990a), the provision of infrastructure and other goods to maintain a population that can serve as a workforce, the maintenance of internal order, and the capacity to defend the population from outside aggression (Mann, 1984a). The need and ability to carry out these functions constantly varies; hence the geographical variety of states and the elusiveness of a precise definition.

One approach has been to show how states have changed over time, which often falls into the developmentalist trap of assuming that states that came into existence as a result of twentieth-century decolonization can and should take on the same form and function as the established European states that imposed their colonial subjugation. Alternatively, a structural approach defines a geographical variation in the form of the state, and differential ability to undertake the standard functions, as a product of the state’s position within the hierarchy of the capitalist world-economy (Flint and Taylor, 2007 [1985]). States in the wealthy core of the world-economy have the ability to provide for most of their population and so to maintain their cohesion and strength. States in the impoverished periphery face internal challenges to their legitimacy. In the former, the state can maintain its authority through creating political consensus regarding its legitimacy. In the latter, coercive power and unstable internal politics are more common.

The geographical variation in the form of the state can be conceptualized as differences in the manner by which the state interacts with the market and civil society. Feminist geographers discourage an understanding of the three spheres as separate. Instead, ‘the market and civil society involve actors and processes that help constitute the state; the procedures and actors of the state similarly influence the market and civil society’ (Fincher, 2004, p. 50). The important conclusions are that the state is multi-faceted and contested. The state is manifest in the actions of the police, in the prosaic sense of imposing guidelines and laws over the way people can act (e.g. seat-belt laws and smoking regulations: Painter, 2004), taxation and the military. The relative power and efficacy of these and other manifestations is a product of a politics between social groups who seek to control or influence the institutions of the state for their own interests. In terms of coercive power, the control of the military and police may be contested between class fractions or ethnic groups (see ethnicity). The size and direction of redistributive programmes is the product of conflicts between the owners of capital who seek to limit the state’s taxation of their wealth and disadvantaged groups seeking security from the vagaries of capitalist economies. Of course, this is not a simple equation, as capital requires enough state involvement to allow for social reproduction (via schools, hospitals and housing subsidies) as well as transport infrastructure and some regulation of economic activity. Feminist geographers highlight that such politics entwine the ‘private’ spaces of the household, the traditional site of unpaid women’s work, with the male-dominated ‘public’ sphere in such a way that they cannot be considered a dualism (see private and public spheres).

Ideology is a central component of maintaining states. The state is a normative ideological construction in both a general and particular sense. First, the belief that states are legitimate universal institutions with a ‘right’ to wield power over individuals is, generally, unchallenged. Second, the history of particular states is constructed to give them a ‘naturalness’ and historical permanency that is a political fiction (Krishna, 1994). The Marxist scholar Antonio Gramsci also points out that the politics within states results in a ruling class that is able to dominate through constructing an ideological consensus around its ‘right’ to rule and a perceived value for the whole population of decisions that greatly benefit a small elite, thus minimizing the need for coercive power (see Hegemony).

The state comprises institutions at various scales linking central and local government. The precise form varies across space and time, but the central government can use local states, with their sense of connectivity to a local population, as means to legitimate itself. On the other hand, local states may challenge the authority of the central state if it is believed that the latter fails to serve local needs (see Regionalism: Kirby, 1993). Globalization and neo-liberalism have put greater responsibility on local governments to carry out state functions and generate their own revenue. New forms of local state governance are being identified that attempt to attract global investment by creating entrepreneurial local
states in which many functions traditionally performed by the state are now the purview of private companies or non-state institutions (Ward, 2005b; see PRIVATIZATION). The result is a reduction in central state power, as states are not so much losing power as a result of globalization but redefining their form and function in a new climate of capital accumulation (Sassen, 1996).

state of nature This phrase featured prominently in the writings of early liberal political philosophers, including most famously Thomas Hobbes, John Locke, Baruch (Benedictus) Spinoza and Jean-Jacques Rousseau (see LIBERALISM). All were concerned with establishing themselves in their own fashion the moral basis of GOVERNANCE and a civil order based in part on their assumptions about what life in the state of nature was like. The phrase points to a kind of reference point or natural (universal) order from which to theorize about the social (Barry, 1999), but it also marks a boundary (imagined and real, historical and geographical) between a condition of being in or of nature to one of being outside of or apart from nature. Emergence from this state of nature, so these discourses suggest, establishes the need for a ‘social contract’, while the particular character of the state of nature (benign, violent etc.) also shapes the character of the required social contract. When taken less literally as a specific time or place, the state of nature serves as a kind of imagined historical geography corresponding to an anarchic society, absent the rule of LAW and without a modern STATE (Smith, M., 2002b). However, the phrase is also quite telling. It points on the one hand to an emergent, modern (EUROPEAN) society concerned with distinguishing and elevating itself in relation to prior and/or culturally ‘Othered’-non-European peoples of the time (mid-seventeenth to early eighteenth centuries), with disquieting implications vis-à-vis IMPERIALISM. At the same time, the phrase points to a preoccupation with defining ‘modern’ society by separating people from nature, presumably (and in Locke, for instance, quite explicitly) legitimating the domination of nature. In addition to the telos of temporal progress, there are definite SPATIALITIES of movement invoked here, not least from the modern, colonizing core to the savage, pre-modern periphery, as well as from the country to the city (Whatmore, 2002a, esp. pp. 64–5; Anderson, 2003: see also MODERNITY; PRIMITIVISM). Contemporary attempts to rethink NATURE/CULTURE binaries may be informed by considerations of how and why this very binary was considered by early liberals to be foundational to modern societies, and how the same binary is constitutive of the emergence of a distinct body of ‘social’ theory (minus the [human] body, of course!). structural adjustment A series of economic measures, often imposed on governments
receiving loans from the INTERNATIONAL MONETARY FUND or the World Bank, designed to encourage exports and increase the resources that governments have available for dealing with short-term balance-of-payments crises. Typical structural adjustment programmes include measures such as reducing government spending, cutting or containing wages, liberalizing imports and reducing restrictions on foreign investment, devaluing the currency and privatizing state enterprises (see also NEO-LIBERALISM; PRIVATIZATION).

structural functionalism A tradition of social theory most closely associated with the American sociologist Talcott Parsons (1902–79), whose central proposition was that the structure of any social system cannot be derived ‘from the actor’s point of view’, but must instead be explained by the ways in which the ‘functional imperatives’ necessary for the survival of any social system are met (Parsons, 1951: see also FUNCTIONALISM; SYSTEM). Parsons insisted that the analysis of any social system requires the conjunction of static (‘structure’) and dynamic (‘function’) components, and constantly accentuated the need to grasp the dynamics of social systems. He attributed crucial importance to the interchanges between systems and between subsystems, and in his later formulations developed a more formal CYBERNETIC model of SOCIETY that drew upon biology as much as it did classical social theory.

Parsons’ influence on modern social theory was extraordinary, even though his views were subjected to a sustained and at times devastating critique. For all his interest in dynamics, it proved difficult to incorporate structural transformation into his model. For all his interest in generalization, his model of the social system seemed to be based on the USA as global exemplar. Today, Parsons’ influence is perhaps greatest in Germany, where Luhmann (1981) and Habermas (1987) have made critical yet creative appropriations of some of his ideas. Parsons’ shadow over human geography has been much shorter. Systems analysis and systems theory in geography had quite other sources, usually far removed from social theory. Even so, Parsons loomed large in Duncan’s (1980) critique of the ‘superorganic’ in Sauer’s CULTURAL GEOGRAPHY and WORLD-SYSTEMS ANALYSIS has been criticized as ‘Parsonianism on a world scale’ (Cooper, 1981).

Alexander (1983); Duncan (1980).

structuralism A set of principles and procedures originally derived from linguistics and linguistic philosophy that seek to expose the enduring and underlying structures inscribed in the cultural practices of human subjects. There have been various structuralisms, all of them dominated by ‘French’ (or at least Francophone) theory, and particularly by Roland Barthes (1915–80) in literary theory, Claude Lévi-Strauss (1908–) in anthropology and Jean Piaget (1896–1980) in psychology. The ideas of all three were introduced into Anglophone HUMAN GEOGRAPHY in the late twentieth century: Harvey (1973) briefly toyed with Piaget en route to a more vigorously materialist analysis of the structures of the SPACE-ECONOMY OF CAPITALISM; Gregory (1978a) drew upon Lévi-Strauss in his search for a mode of ‘structural explanation’ to displace the POSITIVISM on which SPATIAL SCIENCE relied; and Duncan and Duncan (1992) used Barthes as a way-station in their journey towards reading LANDSCAPE not as MORPHOLOGY but as TEXT.

As these descriptions suggest, human geography’s engagement with structuralism was short-lived and functioned as a transition to other approaches that were explored in much more depth. In the most general terms, Peet (1998, pp. 112–46) argues that the move towards structuralism, never complete in geographical thought, represented a search for greater theoretical coherence and rigor. But it did not, in itself, provide a satisfying solution to the problems of EMPIRICISM that provoked human geographers to pursue it in the first place. They turned, instead, towards various forms of MARXISM, including a structural Marxism derived from the writings of Louis Althusser (1918–90) and Nicos Poulantzas (1936–79), whose analytics of power and process left its marks primarily in economic, political and urban geography, towards the philosophy of REALISM, whose modes of structural explanation were more sensitive to historical and geographical specificity than any structuralism; and towards various forms of POST-STRUCTURALISM, which promised a more incisive analysis of desire, DISCOURSE and SUBJECTIVITY.

structuration theory A social theory developed by the British sociologist Anthony
Giddens (1938– ) that seeks to elucidate the intersections between human subjects and the social structures in which they are involved. Giddens’ original purpose was to solve the classical problem of social order. In his view, explanations of social life typically privileged either ‘agency’ (the intentions, meanings and actions of subjects) or ‘structure’ (the logics, limitations and systems of society). Instead, Giddens proposed to treat the production and reproduction of social life as an ongoing process of structuration. In this view, ‘structure’ is implicated in every moment of social interaction – ‘structures’ are not only constraints but also the very conditions of social action – and, conversely, structure is an ‘absent’ order of differences, ‘present’ only in the moments of social interaction through which it is itself reproduced or transformed (Giddens, 1979, 1981, 1984).

Three concepts were crucial to this model:

(1) **Reflexivity**: The production of social life is a skilled accomplishment on the part of knowledgeable and capable human subjects (see human agency).

(2) **Recursiveness**: ‘Structure’ is both the medium and the outcome of the social practices that constitute social systems: rules and resources are drawn upon by actors from structures of signification, domination and legitimation, and these structures are in turn reproduced or transformed through those social practices (see figure).

(3) **Regionalization**: The continuity of social life depends on interactions with others who are either co-present in time and/or space (time-space routinization; cf. time–geography) or who are absent in time and/or space (time–space distanciation).

Giddens argued that these propositions make it possible to analyse the interconnection of routinized and repetitive conduct between actors with long-term, large-scale institutional development in a depth that is denied to both classical social theory and historical materialism.

Giddens fashioned structuration theory through a wide-ranging series of philosophical and theoretical critiques of other writers. Some of his critics complained that it was impossible to rework such radically different ideas into a coherent synthesis; others noted that Giddens worked at such a high level of abstraction that it was far from clear how his general ideas could be brought to bear on empirical enquiry (Gregson, 1989). Although the same agency–structure dualism bedevilled human geography, most human geographers sought a more historically and geographically inflected version of structuration (Thrift, 1983; Gregson, 2005). Aware of parallel debates in social history, and usually more sympathetic to Marxism than Giddens, they mapped the variable and differential intersections of ‘agency’ and ‘structure’ in the production and transformation of specific places, regions and landscapes (Gregory, 1982;

subaltern studies  A body of historiography initiated in the late 1970s by Indian and English historians critical of ‘colonialist and bourgeois-nationalist élitism’ in the writing of Indian history, specifically from the Cambridge School (Guha and Spivak, 1988). Under Ranajit Guha’s founding editorship, the editorial collective included Shahid Amin, David Arnold, Partha Chatterjee, David Hardiman and Gyanendra Pandey, later expanding with Gautam Bhadra, Dipesh Chakrabarty and Sumit Sarkar, all of whom had written important monographs. The first edited volume, Subaltern studies: writings on Indian history and society, was published in 1982. The collective drew on British social history and its renovation of Antonio Gramsci, from whom the concept ‘subaltern’ was adapted.

The timing of this critique of Indian nationalism (particularly Marxist nationalism) – after the suppression of the Naxalbari peasant insurgency and its ‘Maoist’ urban allies, and after Indira Gandhi’s 1975–7 dictatorial emergency – is crucial. The first volumes the collective produced explored peasants’ conscious agency and autonomous subaltern politics (which Cambridge historians had ignored in their emphasis on vertical ‘factions’ in Indian nationalism), a comment on the bankruptcy of institutionalized Indian Marxism. From rumour and militancy under the paternalist mantle of Gandhianism to mismatches between elite and subaltern notions of political community to the disruptive effects of mill workers’ religiosity on industrial discipline, the first four volumes of Subaltern Studies energized debate within Indian history on class, subaltern/elite boundaries and popular politics (Ludden, 2002).

By the late 1980s, shifts between insiders and outsiders in the collective moved subaltern studies into a second phase of historiography, concerned less with a sphere of subaltern politics than with the construction of subaltern power/knowledge and critique of ‘the Enlightenment Project’. While one former insider, Sumit Sarkar, bemoaned ‘the decline of the subaltern in Subaltern Studies’, others saw it as serious response to outsider critiques of ‘subaltern autonomy’, as well as an exploration beyond Gramsci to Michel Foucault’s conception of the subject of power, and to Jacques Derrida’s deconstruction (see Chaturvedi, 2000).

These intellectual shifts, combined with the edited collection by Guha and Spivak (1988), brought subaltern studies to a US – and hence global – academic audience; Edward Said’s introduction to the collection ushered its arrival as the most prolific strand of postcolonial thought. Volumes to follow heightened critique from insiders and outsiders on
GENDER, CASTE, untouchability, charges of bias towards the Bengali intelligentsia, LAW, VIOLENCE, literary and oral traditions, DIASPORA and South India. The collective is now more intellectually eclectic than ever: it continues to be read and responded to from across the world, with a breadth of readership rare for a school of thought emerging from the SOUTH. To be sure, this is partly a consequence of the visibility of key diasporic Indian intellectuals. Subaltern studies has breathed new life into debates over colonial GOVERNMENTALITY, post-colonial nationalism, REPRESENTATION and popular histories of the present (see COLONIALISM; POST-COLONIALISM). As one instance of reception, Frederick Cooper (1994) argues against the idea of an abstract, generalized, binarist colonial rationality and for a dynamic conception of subalternity that ‘put[s] the process of making history into the picture’ (p. 1516). The persisting question is whether the collective remains engaged with subalterns in the noun form used by Gramsci, while also developing more sophisticated tools for engaging subaltern as an adjective, as in ‘subaltern power/knowledge’. The interaction between the first two phases of the collective remains a useful and potentially radical device in understanding spatially layered politics today in the shadows of twentieth-century EMPIRES and nationalisms, and their twenty-first-century successors.

subject/subjectivity This grounds our understanding of who we are, as well as our knowledge claims. All GEOGRAPHY presumes some notion of subjectivity: even ‘objective’ SPATIAL SCIENCE rests on a theory of subjectivity as a foundation for ‘objective’ knowledge. But different theories of the subject provoke different geographical narratives (and vice versa). MARXISM assumptions about the centrality of CLASS to subjectivity have prompted studies of geographies of labour organization, as well as homeownership, residential SEGREGATION and suburbanization, many of the latter aimed at understanding the dissolution of class consciousness in Anglo-American countries in the twentieth century. HUMANISTIC GEOGRAPHY, with its emphasis on the ethical responsibility for human agency and the fullness of human experience beyond economic calculation, invites studies of the social construction of meanings in different LANDSCAPES, and the inauthenticity/authenticity of particular landscapes. Until recently, much of SOCIAL GEOGRAPHY involved locating stable, coherently formed identities (such as ETHNICITY or RACE) in particular places. This was the explicit objective of SOCIAL AREA ANALYSIS. The influences of IDENTITY politics and POST-STRUCTURALISM from the mid-1980s led geographers to be attentive to a wider range of identifications (e.g. DISABILITY; GENDER; SEXUALITY) and problems of overgeneralization. Within FEMINIST GEOGRAPHIES, for example, there is now more sensitivity to how the experiences of different groups of women vary, within and across space. From the perspective of post-structural theories of the subject, this focus on multiplicity is not enough; identity politics (which receives credit – or takes the blame – for the proliferation of politicized identifications through the 1980s and 1990s) has been criticized for taking the fact and stability of identities for granted, and for failing to problematize the processes through which identities are created and differentiated (see RECOGNITION). The subject is even more fully de-centred in ACTOR-NETWORK THEORY, with the emphasis on the agency of non-human actants and ‘a distributed and always provisional personhood’ (Thrift, 2000a, p. 214). Criticizing actor-network theory for an account of subjectivity that flattens human powers of imagination and processes that are not readily reducible to an object world, Thrift (2000a) has articulated a NON-REPRESENTATIONAL style of thinking that focuses not on individual agents, but on a poetic of common practices and skills’ (p. 216, original emphasis) in which ‘persons become, in effect, rather ill-defined constellations rattling around in the world’ (p. 220). A very different rendering of the subject through PSYCHOANALYTIC THEORY has also received more attention since the mid-1990s, in what some have labelled the ‘psychoanalytical turn’ in geography (Philo and Parr, 2003). Callard (2003) has argued, however, that geographers have tended to assimilate psychoanalysis as yet another version of SOCIAL CONSTRUCTION to a disciplinary culture that values agency, RESISTANCE and liberatory cultural politics, and have missed what is most valuable and distinctive about psychoanalytic theory; namely, a theory of the ‘intractability of the unconscious and its imperviousness to political goadings, and the anarchic and implacable movement of the drives’ (p. 300).

Debates about the human subject are vast; they lie at the heart of twentieth-century Western PHILOSOPHY. They are, then, difficult to summarize (for one attempt, see Pile and Thrift, 1995). One organizational device is to distinguish between HUMANIST and...
ANTI-HUMANIST conceptions of subjectivity (Soper, 1986). In geography, this distinction is often articulated through debates about agency and structure (see STRUCCTURATION THEORY). Emphasizing HUMAN AGENCY, humanist versions of subject formation take identity as given in experience. ‘Man’ (some feminists argue that the gendering of this term is by no means incidental: see MASCULINISM; PHALLO-CENTRISM) is at the centre of the world and, in order to be fully human, has the ethical responsibility to act autonomously, to claim his agency (e.g. Ley and Samuels, 1978). Anti-humanists de-centre the subject insofar as they interpret subjectivity as an outcome of subjection to societal ideologies or regulatory techniques, and question the capacity and the authority of individuals to direct their actions self-consciously and autonomously. In the most influential anti-humanist structuralist account of subjectivity, Althusser argued that subjectivity, especially notions of individuality and CITIZENSHIP, are ideological constructs (see IDEOLOGY; STRUCTURALISM). We are interpelled or ‘hailed’ as particular subjects through the institutions of the family, EDUCATION, RELIGION and STATE, and through our own daily practices in relation to them. Subjectivities are built up through these practices of subjection, but these are multiple and sometimes conflicting, always constituted in particular contexts. Despite the seeming role for GEOGRAPHY (as context) in Althusser’s account (Probyn, 2003), in the discipline of geography his theory of the subject often has been rejected as narrowly economic. In cultural studies, particularly FILM studies, Althusser is credited with exactly the opposite effect, for opening a realm for ideology separate from the economy. Drawing on psychoanalytic theory, Althusser posited a more psychologically complex subject for Marxist theory.

There is considerable variation among post-structuralist theories of subject formation, but they have two broad characteristics: they view subject formation as an effect of POWER relations; and they posit the boundaries that define identity as intertwined with processes of disidentification, such that the effect of identification is a fragile and contradictory achievement. To give a sense of the former, in Foucault’s post-structuralist anti-humanist history of Western subjectivity, subject positions are seen to be constructed within and through DISCOURSE. He argues that, from the eighteenth century, discourses of SEXUALITY and individual RIGHTS have altered our perceptions of subjectivity and SOCIETY, and have acted as techniques of disciplinary control (see DISCIPLINARY POWER). They introduced new identities (e.g. the homosexual, the pervert, the hysterical woman), territorialized bodily pleasures as sexual, and brought the individual into new relations with the social through BIOPower.

The intertwined processes of identification and disidentification work differently in different theories. Psychoanalytic theories have offered rich resources for thinking about the difficulties of recognizing difference, traced from a young child’s initial difficulties of registering sexual difference from a loved parent. From the perspective of POST-COLONIALISM, theorists such as Homi Bhabha have drawn on Freud’s notion of the fetish (which functions as a mechanism for both recognizing and disavowing sexual difference) as a way of interpreting the ambivalences of colonial discourse and relations between colonized–colonizer. The concept of ABJECTION, which describes a process by which what is reviled in oneself is denied and relocated in another, offers another means for theorizing stigmatizing discourses of ORIENTALISM, RACISM, ableism and HOMOPHOBIA AND HETEROSEXISM. If psychoanalytic theories draw our attention to the processes whereby what is unbearable or disallowed in oneself and our loved ones is cast outside and used to stigmatize others (but imperfectly – our identity is constantly haunted and destabilized by what is disavowed or abject), DECONSTRUCTION offers a reverse perspective, of the way in which identity is always defined in relation to and inhabited by what it is not (the constitutive outside). Recognizing the exclusions that found every identity, and the necessity of keeping this process of BOUNDARY construction and the purifi- cation of space in view (Sibley, 1995), have been important ideas for recent theorizing about CITIZENSHIP and RADICAL DEMOCRACY (see PRIVATE AND PUBLIC SPHERES).

Anti-humanist accounts have been criticized for closing off the possibilities and responsibilities of agency, RIGHTS, ETHICS and politics. Four responses suggest the opposite. First, discourses are polyvalent: they structure identities without determining them. The identity of ‘homosexual’ can become a resource for persons thus identified when they demand rights in the name of this identity. So too, the meaning of the term ‘queer’ has been reworked, from a stigmatizing identity to a critique of HETERNORMATIVITY (see QUEER THEORY). Second, individuals are subject to multiple discourses and subject positions,
and it is at the disjuncture between various subject positions that agency can be located. Third, identities arise through repeated performances, and this opens possibilities for variation and change, ones that are closed off by positions that see identities as stable (see Performance; Performativity). A fourth response is that psychoanalytic theories that explore the effects of the unconscious widen responsibilities insofar as they call into question our responsibilities for actions of which we are not conscious, such as racism and heterosexism (Culler, 1997).

A key area of contemporary theorizing explores the possibilities for new processes of subject formation whereby we come to understand ourselves and others without creating stigmatized others and hierarchies of difference (in which some groups are seen to be superior to others). The concepts of cyborg and hybridity are two ways of disrupting ideas of pure identities and rigid boundaries. Non-representational thinking offers another model in which: ‘intermediaries and mediaries multiply, so that the “human” “subject” migrates on to many more planes and is mixed with other “subjects” in increasingly polymorphous combinations’ (Thrift, 2000a, p. 220; see also Assemblage). Theorists of radical democracy, such as Mouffe, are sceptical about such possibilities and place emphasis instead on a continual questioning of the inevitable process of boundary construction that must, they argue, necessarily exclude. To evade these exclusions is impossible, but we can insist on a public sphere in which the lines that discriminate inclusion from exclusion are actively contested (for a summary of these arguments, see Pratt, 2004). Others emphasize the need to shift theorizing from ‘the’ subject to intersubjectivity (Rose, 1999b; Probyn, 2003). For Probyn, this draws us back to the ‘hard facts’, such as material inequality, that make such relations and connections difficult.

If theories of subjectivity have always informed geography, what is perhaps newer is the extent to which geography is now woven into theories of the subject. Probyn (2003) notes the interrelations between the retheorization of space and subjectivity: ‘[t]hinking of subjectivity in terms of space of necessity reworks any conception that subjectivity is hidden away in private recesses ... Thinking about how space interacts with subjectivity entails rethinking both terms, and their relation to each other’ (p. 290). Where one is located is constitutive of (and not incidental to) perceptions of self. Thus for Foucault (1980d), the designs of European schools and homes were both reflective of and instrumental in creating the sexualized nuclear family. And one may see oneself differently in different places: Blunt (1994) has argued that nineteenth-century British bourgeois women travellers were defined predominantly in terms of (a rather frail) femininity at home, but in their travels – in Africa, for example – their gendered identity receded (and their health improved), and their race and class positions came to the fore. Constructing a stable boundary for one’s self is an achievement: Davidson (2001) describes the fragility of this construction for those suffering agoraphobia. The construction of coherent places and identities are intertwined social processes: Anderson (1991b) describes how the construction of Chinatown as a stigmatized place apart from the rest of Vancouver was instrumental in cohering a white British Columbian identity. Non-Essentialist readings of subjectivity, in which identifications are conceived as the outcome of power-laden social processes (i.e. not as natural), thus have been read back into the production of space. Places are conceived as open-ended sites of social contestation, and spatial politics involve attending to the moments of closure whereby the identitites of places are stabilized and particular social groups claim a natural right to that space or are entrapped within them. This can involve a dense layering of different subject positions: Anderson (1996) reworks her earlier argument about the production of Chinatown by considering how gender discourses underwrote discourses of nation and race in early-twentieth-century British Columbia.

Geographies are also at the centre of recent efforts to think about new subject formations of hybridity, multiplicity and flexible borders. Spatial metaphors of nomad, mobility, travel, Borderland, Third Space, Networks, connectivity and viscosity, space-off and paradoxical space are some of the terms used to conceptualize these subjectivities. In some of these discussions, geography functions only as metaphor, but the prevalence of geographical terminology in discussions of identity also reflects processes of Transnationalism and Globalization, and increasingly complex geographies of subject formation, which may lead to pluri-local identifications (distributed across and located in different places) or, ironically, the intensification of localized identities (Watts, 1991).
Theories of subjectivity have led geographers to rethink epistemology, methodology, theory and representational strategy. Calls for reflexivity reflect the understanding that knowledge is a social construct contingent on social location: theories of the unconscious indicate the limits of self-reflexivity and the limits of knowledge (Rose, 1997b). Theories of mobile, fragmented identities have encouraged different mapping and writing strategies (Massey, 1997; Pred, 1997). Emphasis on affect and non-cognitive aspects of experience within non-representational styles of thinking have led to many suggestions for theoretical and methodological innovation (Thrift, 2000a; see also qualitative methods). Her engagement with psychotherapy has led Bondi (1999) to read differently: she draws the distinction between intertextual and experiential reading practices.

subsidiarity The principle that authority should be exercised at the most local level consistent with effectiveness, and that higher-level institutions should have only 'subsidiary' functions. The idea originated in Catholic social teaching and became a central concept in theories of federalism. In European Union law and politics, it refers to the division of powers between the EU, member states, and regional and local authorities in a system of multi-level governance. Federalists argue that subsidiarity implies increased devolution to regional bodies. In EU law, however, it mainly protects the rights of national governments vis-à-vis the EU's supranational institutions.

subsistence agriculture A form of organizing food production such that a group (household, village, society) secures food sufficient for its own reproduction over time (see social reproduction). Subsistence production, which includes not only crop production but also hunting, fishing and pastoralism, is typically understood to be based on the direct exploitation of the environment, as opposed to manufacture (Neitschmann, 1973). Subsistence also suggests production for use, as opposed to for exchange, although subsistence groups might share food and other resources for ritual, ceremonial or social reciprocity purposes. Subsistence agriculture can thereby be seen as a form of cultural adaptation by which social groups adapt to and regulate ecosystems of which they are apart (see cultural ecology). In Marxist economics, subsistence production without market involvement of any sort is referred to as primitive economy, the earliest stage of economic development: household subsistence producers with some degree of production for sale, or who purchase some goods in markets are generally referred to as peasants. Because production of surpluses and/or partial commoditization is often associated with the over-exploitation of both nature and direct producers (Blakie, 1985) (see political ecology), subsistence societies appear to be more egalitarian in their social relations, despite the fact that their organization might be highly patriarchal. Although subsistence production is rare in the modern world, it allows for the possibility of substantive group autonomy from both state and market. For that reason, it is occasionally conjured up as a utopian ideal among communards, or invoked as something that ought to be protected in traditional societies (e.g. Norbert-Hodge, 1991).

substitutionism The products of agriculture present special obstacles and barriers for industrial production. Food, with its necessary links to health, well-being, sociability and culture, represents impediments to the simple notion of replacement of foodstuffs by industrial products (appropriationism). But the growth and maturity of the food industry has witnessed a discontinuous but permanent process to achieve the industrial production of food. Goodman, Sorj and Wilkinson (1987, p. 2) refer to the rising proportion of value-added attributable to industrial production in the food system and the gradual replacements of agricultural by non-agricultural products (e.g. of sugar derived from sugar cane, by synthetic sugars) as the twin characteristics of what they call substitutionism. (See also agrarian question; agro-food system.)

suburb/anization Suburbanization is a process whereby people, housing, industry, commerce, and retailing spread out beyond traditional urban areas, forming dispersed landscapes that are still connected to cities
by commuting. These are comprised of diverse suburbs with a variety of social, economic and landscape characteristics and have, as a result, been interpreted in a variety of ways. In terms of their culture and design, they have frequently been criticized for their blandness, lack of community and segregation. These critiques are paralleled by concerns about the environmental impact of suburban landscape forms and ways of life (see Edge City; Exopolis; Ribbon Development; Sprawl).

Low-density, automobile-oriented suburbs are increasingly common features of urban regions across the globe and certain elements of the suburban form, such as gated communities, are springing up in numerous countries (Webster, Glasze and Frantz, 2002). The process of suburbanization is differentiated somewhat by the local or national conditions in which it operates. Lemansky (2006), for instance, describes the character of suburbanization and the creation of master-planned gated communities in post-apartheid South Africa and notes the complex patterns of proximity, social exclusion and connection that exist between wealthy and poor residents of suburban Cape Town. Zhou and Ma (2000), for their part, emphasize the importance of suburbanization in a number of Chinese cities. They argue that it is at a much less developed stage (with suburbs still dominated by central cities) than in the ‘classic’ case of the USA. They also suggest that the role of the strong Chinese state in shaping suburbanization has a great deal to do with the distinctiveness of this case.

Yet, the US case is worth considering as a specific and by no means easily generalizable example of the political economy of suburbanization. The US suburbanization process accelerated in the 1920s with the explosion of automobile ownership in the 1920s. ‘Automobile suburbs’ such as the low-density Country Club District in Kansas City, Missouri, which included the first car-oriented shopping mall, emerged in the 1920s as private developers sought to profit from increased automobile ownership. The Depression of the early 1930s dampened the housing market, making it an unattractive investment for private developers. The state’s subsequent intervention sought to stimulate and regulate the development industry while bolstering the ideological pre-eminence of the private property system (Walker, 1981). By the early 1960s, half the country’s urban population lived in suburbs. This trend in residential suburbanization has been paralleled by manufacturing, commerce and retail, which have all suburbanized. Contemporary authors emphasize the increasing autonomy of US suburbs from traditional central cities, and speak of a ‘postsurburban’ situation (cf. Zhou and Ma, 2000).

Suburbanization is, then, a process that both reflects and constitutes the political and economic geographies of contemporary cities. It is also a focus of those interested in social and cultural questions, particularly around race and gender. Ethnic suburbanization is raising important questions about the validity of arguments about the social homogeneity of suburbs and is also emphasizing the global connectedness of these places (Li, 1998). Nonetheless, suburban geographies are still marked by significant discrimination (see Redlining; Urban Managers and Gatekeepers). The shaping of gender roles and relations in and through suburban space is also a major focus of geographical enquiry. In the postwar period, suburban domesticity became a hegemonic idea through which to reinforce traditional gender relations and connections between women and waged work. Analysis of contemporary relationships between gender, suburbia and work has entailed, among other things, a focus on gender differentiation in travel patterns and accessibility to waged work and public facilities (England, 1993).

sunbelt/snowbelt A popular term describing the polarization of the US space-economy from the 1960s on: it contrasts areas of relative economic decline (especially in manufacturing industry) concentrated in the country’s northeast (the ‘snowbelt’, or ‘frostbelt’: cf. Rustbelt) with those, largely in the south and west, experiencing rapid economic and population growth. This change in the inter-regional division of labour reflects the comparative advantage and competitive advantages enjoyed by sunbelt states through relatively cheap and non-unionized labour, their attractive physical environments, and substantial federal government investment there – as in the aerospace and other defence industries. The term is now frequently applied in other countries: the M4 motorway corridor extending west from London through Swindon to...
Bristol is sometimes referred to as the UK’s sunbelt.

sunk costs Incurred costs that are invariant with output (unlike variable costs) and cannot readily be recouped. In economic geography, sunk costs include those made by a firm in a particular location which, because they cannot be recouped, act as a disincentive to either or both of restructuring and relocation – that is, for the firm exiting either the activity or the place (cf. exit, voice and loyalty). Clark and Wrigley (1995) identified three types of sunk cost: set-up sunk costs (initial investments in plant and machinery, for example); accumulated sunk costs (normal, unrecoupable, costs of doing business); and exit sunk costs (such as those involved not only in abandoning premises and plant, but also in making workers redundant and paying for their pensions). They identify three types of exit strategy that involve acceptance of sunk costs that might not be (fully) recovered: strategic reallocation – using the resources for different activities, which will incur costs (re-equipping a plant, for example, and retraining workers); restructuring, which may involve either or both of plant closure and staff redundancy; and corporate reformulation, which may involve bankruptcy or liquidation.

Clark and Wrigley (1995, p. 210) present 15 separate propositions regarding sunk costs and their importance to their ‘belief that the management of sunk costs across a variety of competitive domains is a vital component in any explanation of the spatial patterns of restructuring’. The accumulation of sunk costs can reduce a firm’s flexibility and thus its ability to respond to the changing pressures associated with globalization. Firms are rarely able to respond costlessly to those imperatives, but those that economize on their sunk costs should be better placed to respond to changing patterns and geometries of supply and demand.

surface A surface is the exterior side of something, or the conceptual boundary from the outside to the inside of a three-dimensional object. The Earth is an irregular spheroid; its surface (of elevation) is ground or sea level. The surface is continuous but, within a study region, sampling height everywhere is impossible. Instead, the surface can be approximated by a series of discrete \((x, y, z)\) data tuples (e.g. \(x\) and \(y\) are longitude and latitude; \(z\) is height above mean sea level), or as a mathematical model (e.g. a trend surface). The \(z\) is not limited to elevation, however: statistical surfaces are also used to visualize ‘hot spots’ of crime, disease, etc., for which local statistics and methods of local interpolation (such as population surface modelling: Martin, Tate and Langford, 2000) are important.

Suggested reading

surveillance The observation or monitoring of social behaviour by individuals and institutions. Typically, surveillance straddles or compresses the geographical distance between its subject(s) and the person(s) tasked with undertaking the monitoring (cf. time-space compression). Virtually all social relations involve elements of surveillance. However, initiatives involving mass or institutionalized surveillance are most often legitimized as a purported means to minimize risk or to enforce some notion of normalization or discipline over a population or place portrayed as hazardous, deviant or pathological (see also security).

Human geography has shown a growing recent interest in surveillance and its imbrications with modernity. A key stimulus has been the writings of French philosopher Michel Foucault, and in particular Surveiller et punir (1975), translated into English as Discipline and punish (1977a [1975]). Through an analysis of Bentham’s panopticon and history of French prisons, Foucault argued that distinctively modern societies were dominated by what he called disciplinary power. This operated through spatially partitioning societies into prisons, workhouses, clinics, barracks, schools and so on. At the same time, architectural techniques were applied to these institutions that allowed persistent visual inspection and control by supervisors. Foucault’s crucial point was that by internalizing this possibility of scrutiny, subjects became ‘normalized’ by monitoring, moderating and controlling their own behaviour.
Since the nineteenth century, these ‘fixed’, architectural models of panopticism have been complemented by a widening range of surveillance machines, many of which now routinely include diffused, interconnecting, computerized devices. Human geographers and others have thus addressed the saturation of contemporary societies with sites of continuous, machinic surveillance. Early research emphasized the social implications of geographic information systems (Pickles, 1995a) and the proliferation of Closed Circuit Television (CCTV) cameras to monitor public spaces (Koskela, 2000). The significance of these practices is not confined to the political and commercial: they also have important military applications. Late-modern war places a premium on persistent surveillance from aerial and space-mounted platforms, including Unmanned Aerial Vehicles (UAVs) or ‘drones’ that transmit real-time imagery to command and control centres and ground troops: these images can feed directly into the identification and execution of targets through what Graham (2009b) calls the ‘algorithmic gaze’.

These practices have spiralled far beyond their initial spheres of application, and an important emerging strand of work in surveillance geography analyses how everyday life in highly computerized societies is coming to be constituted through a burgeoning range of interlinked, digital surveillance systems. This ‘calculative background’, as Thrift (2004b) terms it, is increasingly automated, internationalized and organized through the active agency of computer code. This means that the geographies of life chances, mobilities, access rights, border crossings and service privileges are now sorted through largely invisible systems of digitized surveillance, working simultaneously across multiple geographical scales (Graham, 2005). This happens through sites as diverse as call centres, supermarket checkouts, TV viewing, digital CCTV cameras, neighbourhood GIS systems, mobile phones, webcams, web sites, computerized automobiles, and national border or airport security checkpoints. Rather than emerging as some all-seeing electronic ‘Panopticon’ or some dystopian ‘Big Brother’ drawn from Orwell’s classic novel 1984, however, these systems of surveillance remain fragmented and operate instead as multiple ‘Little Brothers’. Oligoptic rather than panoptic, they do not monitor all spaces and behaviours at all times. Instead, their geographies overlap, cross-cut and intersect in complex ways that are currently poorly understood.

**Suggested reading**

**Survey analysis** The various procedures involved in the collection and analysis of data from individuals, almost invariably using some sort of questionnaire. As such they are a type of extensive research design.

A survey involves several stages. The first is the definition of the research problem, including the formulation of hypotheses and identification of the needed information. The second involves determining the population to be studied, which includes deciding what form of sampling is needed. The next stage involves deciding how the hypotheses will be tested (including the analytical techniques to be employed), and is followed by development of a questionnaire (which should include pre-test stages and pilot investigations).

After administration of the questionnaires the data are prepared for analysis: quantitative data are readily dealt with; qualitative information (such as reported occupations and responses to open-ended questions) has to be handled through the development of coding schemes, increasingly through the use of sophisticated computer software for textual analysis. To ensure statistically reliable results, it is unusual for the number of separate categorical codes (such as social class) to exceed ten, and is typically five or under. The data are then usually entered into a computer database and checked for consistency and gross errors (‘cleaning’ the data set) before the analyses are conducted, although increasingly the responses are entered directly to a computer by the interviewer (whether at a face-to-face interview or in an interview by telephone).

The analysis of surveys consists of four quantitative elements that need to be undertaken simultaneously:

- Evaluating the size effects between variables and by doing so taking account of other variables – what Rosenberg (1978) calls the logic of survey methodology;
- Testing as part of confirmatory data analysis whether the observed effects could have occurred by chance, or whether the lack of an effect is due to inadequate statistical power;
Taking account quantitatively of the complex design of the survey; and

Dealing with non-response and missing data.

To appreciate the issues concerning size of effects and the interplay between variables, consider the following $2 \times 2$ table in which there is a single outcome (happiness) and explanatory variable (age), each being measured on a binary scale:

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Explanatory variable</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Young</td>
<td>Old</td>
</tr>
<tr>
<td>Unhappy</td>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>Happy</td>
<td>C</td>
<td>D</td>
</tr>
</tbody>
</table>

The odds ratio calculated as $(A/B)/(C/D)$ gives the degree of association between the variables: if it is 1 there is no relationship; greater than 1 means that younger people are unhappier; less than 1 suggests that younger people are more likely to be happy. However, these results should not be taken at face value and there needs to be model elaboration (Davis, 1986) to see how the relation changes as account is taken of other variables. This can be clearly seen by examining the following set of $2 \times 2$ tables:

(a) Aggregated data

<table>
<thead>
<tr>
<th></th>
<th>Young</th>
<th>Old</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unhappy</td>
<td>140</td>
<td>120</td>
<td>260</td>
</tr>
<tr>
<td>Happy</td>
<td>50</td>
<td>90</td>
<td>140</td>
</tr>
<tr>
<td>Total</td>
<td>190</td>
<td>210</td>
<td>400</td>
</tr>
</tbody>
</table>

(b) Relation for males

<table>
<thead>
<tr>
<th></th>
<th>Young</th>
<th>Old</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unhappy</td>
<td>120</td>
<td>40</td>
<td>160</td>
</tr>
<tr>
<td>Happy</td>
<td>30</td>
<td>10</td>
<td>40</td>
</tr>
<tr>
<td>Total</td>
<td>150</td>
<td>50</td>
<td>200</td>
</tr>
</tbody>
</table>

(c) Relation for females

<table>
<thead>
<tr>
<th></th>
<th>Young</th>
<th>Old</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unhappy</td>
<td>20</td>
<td>80</td>
<td>100</td>
</tr>
<tr>
<td>Happy</td>
<td>20</td>
<td>80</td>
<td>100</td>
</tr>
<tr>
<td>Total</td>
<td>40</td>
<td>160</td>
<td>200</td>
</tr>
</tbody>
</table>

In (a) the aggregate relation shows no effect as there is an odds ratio of 1, but in (b) and (c) when the analysis is done separately by gender, the odds ratios are 1.79 for males and 2.25 for females. In this case, the effect between age and happiness has been masked by not taking account of gender. The analysis can of course be extended to more than three variables and to include continuous variables (see CATEGORICAL DATA ANALYSIS) but the underlying logic of model elaboration remains the same.

Analysis also has to guard against the Type I error of finding a relation when it does not exist, and the Type II error of not finding a genuine relation (cf. SAMPLING). For the former confirmatory data analysis is used to test for the significance of a relation and to examine confidence intervals; the key here is the absolute sample size. Thus the estimated odds of 2.1 for the relation in the first aggregate analysis has 95 per cent confidence intervals that lie between 1.38 and 3.21, so there is little chance that the aggregate relation is really 1, which would indicate no effect. When no significant relationship is found this may be an outcome of too small a study. If this is the case we can perform a retrospective power analysis (Cohen, 1988) to see if the sample size was large enough to detect an effect. It would have been better, however, to do an initial power analysis before sampling.
SURVEY ANALYSIS

Many surveys have a complex sampling design involving clustering, stratification and disproportionate sampling. These attributes should be taken into account during analysis so as to avoid biased estimates of standard errors and increased likelihood of Type I errors. Clustering, or multi-stage selection of sample units, typically generates dependency so that there is less information than appears. Multi-level models estimate and correct for the degree of dependency even when there are more than two sampling stages. Their results can also be substantively interesting, finding for example that members of the same household tend to vote together (Johnston, Jones, Sarker, Burgess, Propper and Bolster, 2005). Stratification involves grouping the sampling frame into believed-to-be homogeneous groups and thereby reducing standard error. Often there is disproportionate sampling of strata so that having grouped primary sampling units into strata based on percentage ethnic minority population, ethnic areas are over-sampled. This requires at the analysis stage that the over-sampled ethnic areas are down-weighted to their correct population proportion. Sturgis (2004), using data from the 2000 UK Time Use Survey, shows how these factors should be incorporated into the estimates and illustrates the threats to inference if ignored. Longitudinal data analysis faces its own particular analytical problems arising from the analysis of repeated measures over time.

Non-response is a growing problem with surveys. The best approach is to ensure detailed follow-up so that the issue is minimized at the design and collection phase; this is a problem where doing nothing is doing something, and where prevention is better than any cure. We can distinguish between full, or unit, non-response and item non-response, the latter being when the respondent has only answered some questions. For the former, differential weighting can be used to reduce bias by boosting the effective size of subgroups (such as young men) that are under-represented in the survey, but their relative size is known from other large-scale surveys or censuses. There is a danger of increasing standard errors, however, when the variance of the weights is large. Most software for quantitative analysis automatically excludes the entire respondent when any values are missing and this is known as complete case analysis. If the data are missing completely at random (MCAR: Rubin, 1976) this will not bias the results if the observations are excluded but it will reduce the effective sample size. If the data are missing at random (MAR) but the ‘missingness’ depends on recorded information, then complete case analysis can be used, but the determinants of the ‘missingness’ must be included in the analysis to avoid non-response bias. This suggests that at collection phase, variables that should be easier to collect are obtained alongside those that are thought to be difficult (e.g. income may be difficult so also collect information about property value). If the ‘missingness’ depends on unobserved predictors, even after accounting for information in the observed data, then the data are said to be not missing at random (NMAR). In this case, complete case analysis is likely to produce biased results.

There are two main approaches to ‘missingness’, either explicit modelling of the underlying mechanism generating the missing data or some form of imputation (or ‘guessing’) to replace the missing values. A number of ad hoc procedures can be used for the latter, such as carrying the last observation forward, creating an extra category for the missing observation, or replacing missing observations by the mean of the variable used. All can give unpredictable results. Consequently, the only practical, generally applicable, approach for substantial datasets is multiple imputation whereby each missing value is replaced by several (typically less than five) imputed values which come from an imputation model which also reflects sampling variability. A sensitivity analysis can then be undertaken to investigate the robustness of the estimates to differential ‘missingness’.

Survey analysts are aware of criticisms that see quantitative approaches as imposing meaning on people’s attitudes and behaviours. Consequently, as Marsh (1982) argued in her defence of the survey method, researchers have been highly attentive to just such issues, and developments continue to be made. One set of issues relates to whether respondents, particularly from different cultures, understand questions in different ways, or if researchers mean one thing and respondents think they mean something else. Analytical approaches to this treat survey questions as a function of the actual quantity being measured along with an element of interpersonal incomparability that is potentially different for each respondent. The new idea is to use anchoring vignettes as a common reference point (King, Murray, Salomon and Tandon, 2004; King and Wand, 2007) to measure directly and then ‘subtract off’ the incomparable portion. Respondents are asked for their own response.
Sustainability, like sustainability

**Surveying**
To survey is to assess or study a place or population, the salient features of which might then be mapped or recorded. From a cadastral (land ownership) perspective, surveying is to apply the principles of mathematics (geometry and trigonometry) to determine points on the Earth’s surface delimiting a land boundary. Alternatively, a physical scientist might apply the principles of physics, chemistry or biology to survey a site, whereas a polling company uses techniques of statistical inference to survey a population by means of a sample (see Survey Analysis). Geographical research includes not only mathematical/scientific conceptions of surveying but also qualitative methods.

**Sustainability**
Sustainability, like sustainable development, is becoming increasingly difficult to invoke with any critical weight. In fact, it would be fair to say that in critical circles, and among those interested in progressive or radical environmental politics in particular, use of the word will almost certainly elicit a cringe. This may point to an abiding cynicism, but it probably also reflects the proliferation of this term as a form of discursive gloss over disparate material and political projects, including no shortage of mobilizations in corporate ‘greenwash’ campaigns. Indeed, while sustainability as a buzzword does much work to enhance environmental awareness, it may just as easily be viewed as evidence of an increasingly promiscuous convergence of capital accumulation and certain kinds of environmentalism (Katz, 1998). To this may be added the concern that this word – and much more so sustainable development – has become hopelessly co-opted by an instrumentalist and administrative connotation that takes from it any edge as a challenge to prevailing ways of thinking about and relating to one another, and to the non-human world. It is in fact difficult to argue that that any serious progress is being made in the name of this term when, by any reasonable definition and notwithstanding rosy portraits of dematerializing industrial economies, the global political economy and ecology – what Luke (2005) provocatively calls a system of ‘sustainable degradation’ – is characterized by more and more aggregate material and energy throughput, and by greater and greater social inequality (Harper, 2004) (cf. political ecology).

There are nevertheless good reasons to take this word and some of what it conveys seriously, and in particular to differentiate the word from the term ‘sustainable development’. For one thing, sustainability is much less easily and intuitively grafted on to development orthodoxy aimed at sustaining little more than economic growth. Sustainability continues to function more as an ambiguous mantra than as a new paradigm of a post-colonial development agenda, the latter a critique levelled at the institutionalization of sustainable development (Escobar, 1995). Instead, sustainability has been more successfully mobilized in ways that challenge conventional development paradigms – including, for example, in the notion of sustainable livelihoods – and in directing attention towards ‘satisficing’, or meeting basic needs (Sneddon, 2000).

Sustainability is also deployed more concretely in scientific and technical parlance. This includes efforts to develop sustainability indicators (O’Riordan, 2004) to be used as benchmarks, fixed goals by which the abstraction and obfuscation so typical of sustainability discourses might be reined in. It also includes the use of the term in policy-oriented or more applied ecological sciences (e.g. conservation biology) seeking to develop and apply notions of specifically ecological sustainability, particularly when both human and non-human systems exhibit uncertain behaviour. As thin as this literature typically is in conceptualizing human behaviour, important principles such as adaptive management and precautionary action have taken hold
SUSTAINABILITY

Attempts to define and implement principles of sustainability in planning and development policy have sometimes been pursued through the so-called ‘three pillars’ of sustainability, namely economic, social, and environmental or ecological. This is, for instance, a feature of local and regional planning for sustainability as pursued in the UK (Haughton and Counsell, 2004). True, the condition of sustainability in this context is still tethered (legislatively) to the maintenance of economic growth. But one advantage of at least recognizing disparate connotations of sustainability, in terms of these three pillars or otherwise, is that it leaves open the possibility that trade-offs must be made, and that not all efforts to achieve sustainability can be achieved via the win–win optimism that has been a predominant gloss on sustainable development since the Brundtland Commission, and certainly since the 1992 Rio Summit (Adams, 1995). Critical work remains to be done on the government-normalizing dimensions of particular sustainability programmes, specifically the ways in which new political subjectivities and modes of GOVERNANCE arise around the institutionalization of sustainability (see GOVERNMENTALITY). This comprises one way to bring politics into discussions and analyses concerning sustainability.

In fact, this speaks to a bigger problem of politics when it comes to sustainability and sustainable development. Seemingly endless rounds of defining the terms leads to an overriding idealism in policy and academic literatures that can actually obscure attention to changing GENEALOGIES, as predominant connotations evolve shaped in part by prevailing POWER relations. Put another way, and in the spirit of Michel Foucault, tracking the changing meaning of the term must always be situated in relation to the capacity of power to produce these changing meanings. And this is what frustrates many of a critical bent in encountering this word; it seems to preclude or leave unexamined in most iterations questions of power and politics. Revisiting the three pillars noted above, for instance, it is not clear where politics enter and how.

Thus, as opposed to more and more attempts to define the term and pin it down, it might be more useful to consider what questions it invokes. One of these, as Drummond and Marsden (1999) argue, is why sustainability literature is so much characterized by ‘line drawing’ exercises rather than more critical analyses of systemic tendencies for lines to be transgressed. This echoes early critics of both sustainable development and sustainability, who argued that both require direct challenges to CAPITALISM itself as an inherently unsustainable form of economic, social and political organization constituted by and productive of profound social inequalities, and predicated on the mobilization of energy and raw materials increasingly commodified for the purposes of an expanding and inherently expansionist ECONOMY (Redclift, 1987; O’Riordan, 1991; Benton, 1994).

A second question concerns the ways in which sustainability needs to be operationalized as disparate challenges in relation to the so-called environmentalism of the poor versus the environmentalism of the rich (Martinez-Alier, 2002). This would allow affluence to be challenged, while recognizing that the poverty and environmental degradation nexus requires distinct approaches (including not just policies aimed at fostering socially equitable and environmentally benign growth policies, but redistribution via genuine THIRD WORLD debt relief and reparations for COLONIAL plunders).

A third question concerns examination of real-world trade-offs and complex political ecological dynamics involved in the institutionalization of specific programmes aimed at enhancing sustainability, moving past mantras to ask the kinds of hard questions that lend themselves to social science. What, for instance, are the scaled social and environmental implications of reforestation programmes, particularly vis-à-vis reinforcing logging pressure in faraway places (Robbins and Fraser, 2003)? What happens to local level social relations, PROPERTY rights and land-use practices under the influence of international fair TRADE and organic standardization regimes (Mutersbaugh, 2004)? (See also FORESTRY.) What are the social and environmental effects – again across SCALES – introduced by regimes such as ‘FOOD miles’ that stigmatize distance travelled, particularly as these effects ripple through complex COMMODITY CHAINS linking First World markets and Third World agricultural systems (Friedberg, 2004)? While such critically minded, theoretically informed and empirically oriented engagements with real-world instantiations of sustainability oriented policies and programmes might seem to take some of the wind out of sustainability’s sails, they also help ensure that sustainability conveys more than a lot of hot air. SP
sustainable development The concept of sustainable development has become ubiquitous in global debate, but like sustainability, different actors use the phrase to express different visions for economy, environment and society (Adams, 2001). The Brundtland Report of 1987 famously defined sustainable development as ‘development that meets the needs of the present without compromising the ability of future generations to meet their own needs’. This cleverly captures the central paradox of the impact of economic growth on the environment, and yet the need for such growth to alleviate both present and future poverty (often spoken of as intra- and inter-generational equity).

Radical critiques of the unsustainable nature of development have included calls for zero economic growth and critiques of industrialization, consumerism and free market economics. However, mainstream thinking about sustainable development has centred on ‘market environmentalism’ and continued economic growth, adapted to ensure that the capacity of the planet to provide raw materials and absorb wastes is not overstretched (Low and Gleeson, 1998). This is to be achieved through the ‘greening’ of industry and society, ‘green’ consumerism and efficient production systems that minimize wastage, pollution and negative social impact. Under market environmentalism, growth and consumption are the engine that drives the creation of sustainable environments and livelihoods.

Such changes demand ‘ecological modernization’, the pursuit of rational, technical solutions to environmental problems and more efficient institutions for environmental management and control (Hajer, 1995). This involves new partnerships between state and private enterprise, including market-based incentives, self-regulation by business, strong government and an efficient state bureaucracy. The feasibility of this approach is limited by the erosion of state power by globalization and free trade. Many developing countries in particular display significant weaknesses in governance, and powerless civil society institutions.

Mainstream thinking about sustainable development became established at the United Nations Conference on Environment and Development (UNCED, or simply the ‘Rio Conference’), held at Rio de Janeiro in Brazil in June 1992 (Chatterjee and Finger, 1994). This meeting produced a vast encyclopedia of ideas in Agenda 21 (over 600 pages long), the Convention on Biological Diversity (http://www.biodiv.org/default.shtml) and the Framework Convention on Climate Change (http://unfccc.int/2860.php).

At Rio, sustainable development was interpreted primarily in terms of global environmental change (biodiversity depletion and climate change), reflecting the agenda of industrialized Northern countries. Complex and controversial issues of global poverty or north–south inequality were discussed less effectively. However, this emphasis changed at the World Summit on Sustainable Development (WSSD), in Johannesburg, South Africa, in 2002. This followed the United Nations Millennium Summit in September 2000 and agreement on a series of Millennium Development Goals (www.developmentgoals.org). Poverty was central to debate at Johannesburg. The Johannesburg Plan of Implementation addressed the eradication of poverty as well as issues such as unsustainable patterns of consumption and production, the protection and management of the natural resource base of economic and social development, globalization and health (www.johannesburgsummit.org).

symbolic interactionism A social theory that focuses upon the social construction of the self and objects through interaction with others. Based on the theoretical formulations of the philosopher G.H. Mead (1934), its sociological implications were developed by Herbert Blumer (1969) and others. The theory posits that the self and social organization more broadly are formed by an ongoing process of the interpretation of meanings. As such, the theory is opposed to notions of structures, which are not reducible to ongoing interaction. More structurally inclined theorists have accused it of being individualistic and voluntarist. Anti-humanism in geography criticizes its primary emphasis on human interaction.

system A set of elements organized so that each is either directly or indirectly interdependent on every other, usually in some form of network (cf. graph theory; social network). Many analysts argue that systems must have a function, goal or purpose – even if this is only the maintenance of the system itself.
(see FUNCTIONALISM; STRUCTURAL FUNCTIONALISM). Some have a clear, separate existence and function – as with a central heating system – but many geographical studies involve the pragmatic isolation (or ABstraction) of linked parts from a larger whole (such as a METROPOLITAN AREA): where such abstractions are somewhat arbitrary, the system studied may yield few valuable conclusions (and be categorized as a chaotic conception).

Systems analysis involves four main decisions regarding the object of study:

- **Whether it is to be conceptualized as open or closed.** A closed system has no links to a surrounding environment – either as a source of energy (as in ECOSYSTEMS) or as a receptacle for by-products of its operation (as in POLLUTION): an open system (which is by far the commonest condition) interacts with its milieu.
- **Whether it can be divided into subsystems,** comprising separate clusters of interdependent elements weakly linked to each other.
- **Whether the links involve flows and causal relationships, or are presented as black boxes.** Systems of flows involve the movement of materials, ideas and people (as in TRADE, MIGRATION and COMMUTING); causal systems involve links that transmit clearly defined consequences (as in A generates B; e.g. assuming constant demand, an increase in the supply of a good leads to a reduction in its price): a black box incorporates links that may be causal, but for which the processes involved are not understood.
- **Whether the system involves FEEDBACK,** either positive or negative.

The concept of a system and the formal protocols of systems analysis (many of them derived from engineering) were introduced to GEOGRAPHY during its QUANTITATIVE REVOLUTION, and were seen by some as providing both substantive and methodological links between HUMAN and PHYSICAL GEOGRAPHY (see also ECOLOGY; GENERAL SYSTEMS THEORY; HUMAN ECOLOGY; POLITICAL ECOLOGY). More generally, the concept of a system is applied descriptively in a wide range of contexts to refer to sets of interdependent phenomena, without adopting any of the more formal concepts associated with systems analysis.

Bennett and Chorley (1978); Huggett (1980); Wilson (2000).
**taken-for-granted world** The realm of **everyday life**, frequently unreflective, where convention and routine prevail, leading to the accumulation of the attitudinal norms and habitual practices that define a subculture. The taken-for-granted world was **inspired by humanistic geography** through **ethnographic** and other interpretative methods inspired by the philosophical traditions of **German constitutive phenomenology** and **American pragmatism** (Ley, 1977). Also relevant is Pierre Bourdieu’s concept of **habitus**, with its emphasis on **class-based subcultures** with varied resources to bring to everyday social projects. The centrality of **power** in everyday life has been also been drawn out more fully by the French philosophers **Michel de Certeau** and **Henri Lefebvre**.

**Suggested reading** Werlen (1993, ch. 3).

**tariff** A tax levied by a government on the importation of a **commodity** made abroad. Governments impose tariffs on foreign-made imports for multiple reasons, including to protect domestic producers from foreign competition, to correct a trade deficit, to give preference to imports from certain countries over others, or, contrarily, to retaliate against another country’s preferential tariff regime.

Preferential tariffs designed to privilege or punish particular exporting countries date to imperial trading practices, which were often organized within networks of ‘imperial preference’. But it was in the context of nineteenth-century **imperialism** that British industrialists began the rhetorical inflation of free trade and the political struggle to reduce tariffs (Sheppard, 2005): they wanted to sell their products to foreign and domestic markets, and also saw the advantages of tariff-free food imports for feeding and maintaining a cheap workforce (Merrett, 1996). Early economists such as David Ricardo helped the industrialists make their case with academic arguments about the gains from **trade**, and until the 1930s, the cause of free trade and tariff reduction spread around the world, albeit within limits created by inter-imperial struggles (including the immense upheaval of the First World War). During the Great Depression, however, in the rush to protect their domestic capitalists from the global crisis of over-accumulation, governments imposed steep tariffs on foreign imports. The resultant ‘tariff walls’ drastically reduced world trade and created much more autarchic or self-contained national economies: this territorialization of economies set the geographical pattern for the **distinctively national regimes of accumulation** based on **Fordism** that characterized the mid-twentieth century (see Lash and Urry, 1987; Harvey, 1989b; Mitchell, 1998, 2002d).

The Fordist pattern of economic nationalization was also influenced by global politics, the rise of **communism** and, most notably, the national mobilizations forced by the Second World War. However, as the war drew to a close, the cause of free trade was launched again with the American-led meetings at Bretton Woods, which led to the General Agreement on Tariffs and Trade or **GATT** in 1947. Some joke that GATT in fact stood for the General Agreement to Talk and Talk, because, despite unending American pressure and resulting rounds of talks, other countries were reluctant to quickly remove their tariff walls, as they faced the prospect of rebuilding their war-torn economies. The USA, by contrast, had emerged from the war with its economy unscathed and eager to expand markets for its products worldwide. American negotiators pushed for a more open global free trade system that could absorb the US trade surplus, and slowly but surely they prevailed: the crowning achievement was the establishment of the **World Trade Organization** in 1994 (Peet, 2003). However, by the 1990s the US trade surplus had turned into a large and fast-growing deficit; thus, in the years since its inception the WTO has had to deal with increasing complaints by developing countries that the USA is abandoning free trade and – ironically albeit unsurprisingly – imposing tariffs on foreign products (Wallach and Woodall, 2004).

**Taylorism** A set of workplace practices developed from the principles of ‘scientific management’ by the American engineer **Frederick W. Taylor** (1911) from his
systematic time-and-motion studies of the labour process in American factories. The core principle involved breaking down production activities into their simplest, standardized components and linking them in precisely coordinated, closely supervised sequences. This imposed a strictly disciplined choreography on the workplace, a sort of mechanized ballet, and workers often resisted its introduction. Taylorism was designed to enhance overall efficiency by reducing the scope of activity of individual workers and optimizing the performance of individual tasks, but the logic of distinguishing between close supervision and standardized activities also accentuated the separation of conception and execution of tasks in the workplace.

For this reason, analysts such as Braverman (1974) have associated the widespread introduction of Taylorist principles with thedeskilling or degradation of work. The result is a distinctive occupational division of labour, in which unskilled workers execute simple, repetitive shop-floor fabrication functions, while skilled technical and managerial staff perform functions related to research, product design, process and quality control, coordination, finance and marketing. The economic outcomes for workers depend on the wider social and political context in which the production systems are embedded. Under the terms of classical Fordism in the USA and western Europe, for example, the array of institutions governing collective bargaining and wage determination increased the likelihood that even unskilled workers might enjoy a decent living and enjoy tolerable working conditions. The application of Taylorist principles elsewhere, in parts of Asia, Africa and Latin America, was not normally accompanied by such institutional frameworks, however, leading to a more ‘primitive Taylorization’, based on the ‘bloody exploitation’ of labour (Peck and Tickell, 1994, pp. 286–7).

As Clark (1981) and others have observed, during the postwar period, in which Taylorist principles gained their widest acceptance, large firms organized along Taylorist lines would often segregate skilled and unskilled functions in separate plants, producing a spatial division of labour defined by the pre-existing geography of labour supply, wage rates and social relations (see also Labour Geography). Subsequent methods of work organization associated with post-Fordism are generally regarded as having reversed the task fragmentation and separation of conception and execution characteristic of Taylorism. But Schoenberger (1997) and others suggest that organizational innovations such as just-in-time production were developed by eliminating wasted time in production through the use of precisely the same tools of time-and-motion study pioneered by Taylor himself.

**Teleology** Teleological enquiry is motivated by the belief that there is an ultimate purpose or design at work within the world, and that all elements and events, whether we are conscious of it or not, are pre-configured to realize that purpose or design. The teleological end reaches back to explain everything that precedes it. The origins of teleology lie in Greek philosophy, especially the writings of Aristotle and the concept of a final cause, which proposes that phenomena take on their peculiar properties because they enable some final end or purpose (telos) to be met. To use Aristotle’s own example, humans do not see because of a series of prior biological processes that produce eyes; rather, eyes are produced in order to meet the purpose of seeing. The teleological end of seeing arranges biological conditions such that eyes eventuate. As Aristotle had it, ‘Nature adapts the organ to the function, and not the function to the organ.’

Teleology as a form of argumentation is found in a diverse range of enquiry. It is perhaps best known within Christian theology – from St Thomas Aquinas’ (1225–74) five proofs of God’s existence, to recent (unsuccessful) arguments in the US court system to justify classroom teaching of ‘intelligent design’. Within the humanities and social sciences, the teleological writings of the German philosopher G.W.F. Hegel (1770–1831) have been pivotal, in large part because of their influence on others, especially Karl Marx (1818–83). Hegel argued that human history was teleologically directed to the unification of spirit (Geist) and proceeded through a dynamic process of negation and contradiction (the dialectic). At some historical juncture (which Hegel said happened to be his own time), the negations and contractions were finally comprehended by individual human minds as a unity, at which point the mandate of history was fulfilled; history’s teleological purpose was reached. Marx invoked a similar teleology in his own historical scheme, also propelled also by negation and contradiction. But in Marx’s view, history was moved not by contradictions of spirit becoming unified, but by a set of contradictory physical–social
relationships within successive MODES OF PRODUCTION, and unification occurred not within individual minds but very much outside in the world of people’s material lives and practices. Marx argued that history’s teleology was marked by distinct stages of completion, with CAPITALISM, the epoch in which Marx lived, merely the penultimate one. History’s ultimate purpose, the negation of all negation, would manifest in what necessarily came next, the final stage, the end of history, COMMUNISM.

Teleological arguments are criticized on many grounds, including: they are not empirically testable and are thus unfalsifiable; they reverse the temporal sequence of cause and effect (effects determine causes); causal mechanisms are either absent or not well specified; and they deny human beings free will, confining them within an iron cage of historical inevitability. Nevertheless, teleological arguments can be found in two distinct bodies of work in modern HUMAN GEOGRAPHY. The first was in studies of MODERNIZATION in the 1960s that were (mis)informed by Rostow’s (1960) STAGES OF GROWTH model to depict – and predict – the inevitable spatial DIFFUSION of modernization across the landscape of a developing economy (Gould, 1969b). The second was in the early writings of some Marxist geographers who saw capitalism’s CRISES as inevitable way-stations towards the end point of its final destruction and overthrow (Smith, 2008 [1984]).

**terms of trade** A name in economics for the ratio between a price index of a country’s exports and a price index of its imports. Amongst advocates of export-led DEVELOPMENT, ‘improving the terms of trade’ traditionally meant increasing the ratio of profits from exports vis-à-vis the costs of imports. As such, it was part of the Washington consensus amongst development economists that export surpluses were better than import substitution for developing countries. But now, in the context of increasing dissensus over such axioms, a second, more literal, meaning of ‘terms of trade’ has come to the fore as criticism of NEO-LIBERALISM have sought to decode the ways in which the terminology of recent global and regional TRADE agreements obscures how they enshrine neo-liberal norms of government across wide swathes of social, political and even ecological as well as economic life (Peet, Borne, Davis et al., 2003; McCarthy, 2004). Terms-of-trade legalese such as TRIPs (which in the WORLD TRADE ORGANIZATION (WTO) stands for agreements on Trade Related Intellectual Property) and TRIMs (Trade Related Investment Measures) have thereby been debunked as elements of a narrow neo-liberal, free-market fundamentalist agenda that sets constraints on democratic governance over everything from food safety to DEVELOPMENT policy by giving private corporations quasi-constitutional rights to sue governments (Sparke, 2005). ‘Because its terms are so broad,’ argue two critics of the WTO’s terms of trade, ‘the WTO has managed to intervene in domestic policies all over the planet’ (Wallach and Woodall, 2004, p. 2). Countering this takeover, Wallach and Woodall point out that the neo-liberal project therefore involves repeatedly expanding what were originally meant to be simple agreements on free trade into neo-liberal legal rules governing practically everything. This terms-of-trade overreach, they note, is ironically marked in the terms themselves such that ‘you can identify which WTO agreements have least connection to trade by which have the “Trade Related” label slapped on them’ (ibid., p. 2). It remains a credit to the critical wisdom of Marx and Engels that they foresaw precisely this terms-of-trade takeover in the Communist manifesto, when they described the wholesale transformation of medieval life through the free trade fetish of the capitalist business CLASS. ‘The bourgeoisie,’ they thereby argued, ‘has drowned the most heavily ecstatics of religious fervour, of chivalrous enthusiasm, of philistine sentimentalism, in the icy water of egotistical calculation. It has resolved personal worth into exchange value, and in place of the numberless indefeasible chartered freedoms, has set up that single, unconscionable freedom – Free Trade’ (Marx and Engels, 2002 [1848]).

**terra nullius** A legal doctrine enshrined in eighteenth-century European LAW that legitimized the annexation of ‘uninhabited lands’ by settlement as an acknowledged means, alongside conquest and secession, for the proper conduct of colonization by ‘civilized’ nations. Such lands were not literally uninhabited; rather, the colonizers cast their existing inhabitants as too ‘primitive’ to merit political recognition (cf. PRIMITIVISM). *Terra nullius* was instrumental in the European dispossession of indigenous peoples in so-called settler colonies, such as Australia, which has been the subject of political COLONIALISM; struggle and legal redress ever since. (See also COLONIALISM; SETTLER SOCIETY.)

**Territorial Integrity**

A term in international law and, increasingly, critical geopolitics, that has two main meanings: *territorial preservation* and *territorial sovereignty*. Its meaning of territorial preservation establishes a right to the preservation of a state’s existing boundaries, and prevents secession or territorial conquest by other states. Territorial sovereignty or inviolability allows a state to exercise its power within those boundaries, without intervention or prohibition from external actors (see Akweenda, 1989). Both senses of the term are enshrined and protected by key clauses of Article 2 of the founding Charter of the United Nations.

While there is an element of necessary fiction in the idea that states are in control of, and therefore exercise sovereignty over, their entire territory, this has provided a framework within which international law has operated. The norm of territorial preservation conditioned decolonization in Africa, and helped to frame the international context of the break-up of the Soviet Union. Territorial sovereignty has been held as a guiding principle of the international system where, for actions that do not have an effect beyond its borders, a state has been held to be sovereign. This is what the European Union calls *internal competence*. Thus international law is built around three core principles: sovereign equality of all states; internal competence for domestic jurisdiction; and territorial preservation of existing boundaries. What this means is that any challenge to the ‘monopoly of legitimate physical violence’ that states are held to have within their territory is necessarily a challenge to territorial integrity by infringing on the spatial extent of their sovereignty.

Territorial integrity in the sense of territorial sovereignty has come under increased pressure in recent years, with humanitarian intervention or the ‘responsibility to protect’ civilian populations legitimating external intervention in internal jurisdiction. The doctrine of ‘contingent sovereignty’ promoted by the Bush administration in the ‘war on terror’ (Elden, 2006; see also Terrorism; War) held that state sovereignty is dependent on adherence to codes of behaviour – notably not harbouring terrorists or pursuing ‘weapons of mass destruction’ – and violation of these norms legitimates pre-emptive action (Elden, 2005, 2007a,c). Yet at the same time territorial preservation has been held as a dominant organizing principle, with a widespread reluctance to support independence secession movements or rethink the boundaries of existing states.

**Territorial Justice**

The territorialization of the principles of social justice. This involves examining the conditions under which wealth and social well-being are produced, distributed and consumed (Perrons, 2004). Hence, social justice can only be giving meaning in the context of a particular set of social relations. Using territorial justice to make judgements over the justness or otherwise of societies is complicated in three ways: first, there are the difficulties posed by the ecological fallacy; second, there are issues over the appropriateness of the spatial definition of the territorial units; and, third, the achievement of territorial justice has to be set against what this might mean for other forms of justice (Smith and Lee, 2004).

Smith and Lee (2004).

**Territorial Sea**

A jurisdictional zone of the ocean, extending a maximum of 12 nautical miles from the baseline (United Nations, 1983, Article 3) and including air space, sea bed and subsoil. The territorial sea is the ocean zone most exposed to human pressure and resource use. The 1982 United Nations Convention on the Law of the Sea (UNCLOS) extends the sovereignty of coastal states to include the territorial sea. Within the zone, other nations have few prerogatives beyond the right of ‘innocent passage’, which recognizes the transit right of foreign flag merchant vessels provided that it is peaceful and not prejudicial to the good order or security of the coastal state concerned.

**Territoriality**

Either the organization and exercise of power, legitimate or otherwise, over blocs of space or the organization of people and things into discrete areas through the use of boundaries. In studies of animal behaviour, spatial division into territories is seen as an evolutionary principle, a way of fostering competition so that those best matched to their territory will have more surviving offspring. With human territoriality, however, spatial division is more typically thought of as a strategy used by organizations and groups to organize social, economic and political activities. From this viewpoint, space is partitioned...
into territorial cells or units that can be relatively autonomous (as with the division of global space into territorial NATION-STATES) or arranged hierarchically from basic units in which work, administration or SURVEILLANCE is carried out through intermediate levels at which managerial or supervisory functions are located to the top-most level, at which central control is concentrated. Alternative SPATIALITIES of political and economic organization, particularly hierarchical NETWORKS (as in the WORLD-CITY network) or reticular networks (as with the INTERNET), can challenge or supplement the use of territoriality.

Theoretically, territoriality can be judged as having a number of different origins including: (1) as a result of explicit territorial strategizing to devolve administrative functions but maintain central control (Sack, 1986); (2) as a secondary result of resolving the dilemmas facing social groups in delivering PUBLIC GOODS (as in Michael Mann’s, 1984b, sociology of territory); (3) as an expedient facilitating coordination between capitalists who are otherwise in competition with one another (as in MARXIST theories of the state); (4) as the focus of one strategy among several of GOVERNMENTALITY (as in Michel Foucault’s writings); and (5) as a result of defining boundaries between social groups to identify and maintain group cohesion, as in the writings of Georg Simmel (Lechner, 1991) and Fredrik Barth (1969), and in more recent sociological theories of political IDENTITY (Agnew 2003b). Whatever its origins, territoriality is put into practice in a number of different if often complementary ways: (1) by popular acceptance of classifications of space (e.g. ‘ours’ versus ‘yours’); (2) through communication of a SENSE OF PLACE (where territorial markers and BOUNDARIES evoke meanings); and (3) by enforcing control over space (by SURVEILLANCE, POLICING and legitimation).

There are important cultural and historical dimensions to territoriality. Churches and polities (states, empires, federations etc.) have been the most important users of territoriality. Some churches (such as the Roman Catholic Church) and some states (such as the United States) have more complex and formally hierarchical territorialities than others. Today, TRANSNATIONAL CORPORATIONS and global businesses erect territorial hierarchies that cut across existing political ones. So, even as some users of territoriality fade away, others emerge. Though varying in precise form and complexity, therefore, territoriality seems always to be with us.

territorialization The dynamic process whereby humans and their affairs are fixed territorially in space, by a range of actors but primarily by STATES. On the contrary, deterritorialization signifies a growing tendency for states, in the context of global CAPITALISM, to encounter and often encourage an uprooting of people and things with massive social, psychological, and political consequences. Reterritorialization is the reverse of this process.

In some usage, particularly that of Deleuze and Guattari (e.g. 1972), employment of deterritorialization seems to simply refer to the breakdown of TERRITORIALITY in thought and practice. EPistemologically juxtaposing ‘State philosophy’ with ‘nomad thought’, Deleuze and Guattari associate territorialization with the former and deterritorialization with the latter. ONTOLOGICALLY, however, there could be quite different territorial systems at play over time as, for example, with pre- and post-colonial contact between colonizers and natives leading to the breakdown of one system, followed by a period of deterritorialization before the imposition of a new territoriality. Crucial to the concept of deterritorialization with Deleuze and Guattari is the claim that ‘Processes are becomings, and aren’t to be judged by some final result but by the way they proceed and their power to continue, as with animal becomings, or nonsubjective individuations’ (Deleuze, 1995, p. 146).

More typically, two other approaches tend to dominate contemporary usage. In the first case, TERRITORY is posed as a physical ‘base’ for human activities and deterritorialization is viewed as either the lessening importance of local constraints or the weakening of the impact of physical distance on EVERYDAY LIFE. The increased speed of financial and other transactions, the so-called conquest of space by time (cf. TIME-SPACE CONVERGENCE) and the advent of CYBERSPACE are frequently invoked to explain what deterritorialization is held to describe. Such ideas are part and parcel of much discussion of economic GLOBALIZATION. In the second case, territory is perceived as a spatial assemblage of POWER relations and IDENTITY strategies. From this perspective, such ideas as the ‘end of territory’ and the rise of network space are linked to the recent onset of a worldwide deterritorialization
(e.g. Badie, 1995; Hardt and Negri, 2000: cf. NETWORK SOCIETY). Others tend to see deterritorialization in terms of the weakening of territorial identities in the face of globalization (e.g. Mitchell, 2000) or the creation of ‘NON-PLACES’ (Augé, 1992).

Though frequently used as a stand-alone term, deterritorialization makes most sense when used in the context of territorialization. For example, the ‘disappearance’ of territory at one scale can see its recomposition at others (Brenner, Jessop, Jones and Macleod, 2003). At the same time, deterritorialization undoubtedly has metaphorical currency (see METAPHOR) when applied, for instance, to the fading of intellectual boundaries, and some descriptive utility when used as a synonym for the instability and unravelling of territorial space. Notwithstanding the ambiguities inherent in the terms, in a world in which evidence for both territorialization (e.g. the Israel–Palestine Separation Barrier) and deterritorialization (e.g. the European Union Schengen passport zone) is not hard to come by, their usage suggests a dynamism to the forms of territories and territorialities that some writers have been all too willing to deny.

territory A unit of contiguous space that is used, organized and managed by a social group, individual person or institution to restrict and control access to people and places. Though sometimes the word is used as synonymous with PLACE or SPACE, territory has never been a term as primordial or as generic as they are in the canons of geographical terminology. The dominant usage has always been either political, in the sense of necessarily involving the POWER to limit access to certain places or regions, or ethological, in the sense of the dominance exercised over a space by a given species or an individual organism. Increasingly, territory is coupled with the concept of NETWORK to help understand the complex processes through which space is managed and controlled by powerful organizations. In this light, territory is only one type of SPATIALITY, or way in which space is used, rather than the one monopolizing its employment. From this perspective, TERRITORIALITY is the strategic use of territory to attain organizational goals.

Territory is particularly associated with the spatiality of the modern STATE with its claim to absolute control over a population within carefully defined external BORDERS (Buchanan and Moore, 2003, p. 6). Indeed, until Sack (1986) extended the understanding of human territoriality as a strategy available to individuals and organizations in general, usage of the term ‘territory’ was largely confined to the spatial organization of states. In the social sciences, such as sociology and political science, this is still mainly the case, such that the challenge posed to territory by NETWORK forms of organization (associated with GLOBALIZATION) is invariably characterized in totalistic terms as ‘the end of geography’. This signifies the extent to which territory has become the dominant geographical term (and imagination) in the social sciences (Badie, 1995). It is then closely allied to state sovereignty. AS SOVEREIGNTY is seen to ‘erode’ or ‘unbundle,’ so goes territory (Agniew, 1994). From this viewpoint, territory takes on an epistemological centrality (see EPistemology) in that it is understood as absolutely fundamental to MODERNITY. As such it can then be given an extended meaning to refer to any socially constructed geographical space, not just that resulting from statehood (Scivololetto, 1983; Bonnemaison, 1996; Storper 1997a). Especially popular with some French-language geographers, this usage often reflects the need to adopt a term to distinguish the particular and the local from the more general global or national ‘space’. It then signifies the ‘bottom-up’ spatial context for IDENTITY and cultural difference (or place) more than the ‘top-down’ connection between state and territory.

The territorial state is a highly specific historical entity. It first arose in EUROPE in the sixteenth and seventeenth centuries. Since that time, political power has been seen as inherently territorial. Politics take place only within the institutions and the spatial envelope of the state as the exclusive governor of a definite territory. We also identify political territory with social space, perceiving countries as ‘state-societies’ (Hirst, 2005, p. 27). The process of state formation has always had two crucial attributes. One is EXCLUSIVITY. All of the political entities (the Roman Catholic Church, city-states etc.) that could not achieve a reasonable semblance of sovereignty over a contiguous territory have been delegitimized as major political actors. The second is MUTUAL recognition. The power of states has rested to a considerable extent on the recognition each state receives from the others by means of non-interference in so-called internal affairs (see SOVEREIGNTY). Together, these attributes
have created a world in which there can be no territory without a state. In this way, territory has come to underpin both nationalism and representative democracy, both of which depend critically on restricting political membership by homeland and address, respectively.

In political theory, control over a relatively modest territory has long been seen as the primary solution to the ‘security dilemma’: to offer protection to populations from the threats of anarchy (disorder: cf. anarchism), on the one hand, and hierarchy (distant rule and subordination), on the other. The problem has been to define what is meant by ‘modest’ size. To Montesquieu (1949 [1748], p. 122), the enlightenment philosopher, different size territories inevitably have different political forms: ‘It is, therefore, the natural property of small states to be governed as a republic, of middling ones to be subject to a monarch, and of large empires to be swayed by a despotic prince.’ Early modern Europe offered propitious circumstances for the emergence of a fragmented political system primarily because of its topographical divisions. Montesquieu (1949 [1748], pp. 151–62) further notes, however, that popular representation allows for the territorial extension of republican government. The founders of the USA added to this by trying to balance between centralizing certain security functions, on one side, and retaining local controls over many other functions, on the other (Deudney, 2004). The recent history of the European Union can be thought of in similar terms (Milward, 2005).

Human activities in the world, however, have never conformed entirely to spaces defined by proximity as provided by territory. Indeed, and increasingly, as physical distance proves less of a barrier to movement, spatial interaction between separated nodes across networks is an important mechanism of geographical sorting and differentiation (Durand, Lévy and Retaillé, 1992). Sometimes posed today in terms of a world of flows versus a world of territories, this is better thought of in terms of territories and/or networks of flows rather than one versus the other. Territories and networks exist relationally rather than mutually exclusively. If territorial regulation is all about tying flows to places, territories have never been zero-sum entities in which the sharing of power or the existence of external linkages totally undermines their capacity to regulate. If at one time territorial states did severely limit the local powers of trans-territorial agencies, that this is no longer the case does not signify that the states have lost all of their powers: ‘Territory still matters. States remain the most effective governors of populations… The powers to exclude, to tax, and to define political rights are those over which states acquired a monopoly in the seventeenth century. They remain the essentials of state power and explain why state sovereignty survives today and why it is indispensable to the international order’ (Hirst, 2005, p. 45).

terrorism Organized violence that deliberately targets civilians and that is intended to sow fear among a population for political purposes. It is a deeply contested term, because many writers restrict the term to non-state actors and exclude the state from the (direct) use of such violence; they argue that since the state lays claim to the legitimate use of physical force, then by definition it is incapable of the deliberate targeting of a civilian population, which is an offence under international humanitarian law (see just war). It then follows that all violent challenges to the authority of the state, including armed resistance to military occupation (see occupation, military), risk being identified as terrorism. Against this, others argue more persuasively that states have often used violence to intimidate populations, either their own or those of other countries, through a systematic assault on ‘enemy’, ‘alien’, ‘dissenting’ or ‘subversive’ bodies and their associated places. Indeed, the term originates in the Reign of Terror carried out by the Committee of Public Safety in 1793–4 to purge the revolutionary French republic of its ‘internal enemies’. Modern state terror includes both: (i) the exemplary violence of colonial wars and counter-insurgency, Stalin’s campaign of terror against dissidents in the 1930s, the German Blitz over London, the holocaust, the saturation bombing of German cities such as Hamburg and Dresden, and the nuclear bombs dropped on Nagasaki and Hiroshima during the Second World War (Hewitt, 1987: see also ethnic cleansing; genocide); and also (ii) more insidious forms of violence that work to extend the envelope of fear within their target populations through arbitrary detention, disappearance and torture (including the campaigns perpetrated by authoritarian regimes in Central and South America in the 1970s and 1980s, often with the support of the USA).
TERRORISM

Hewitt, 2001: see also EXCEPTION, SPACE OF). In addition, and making a distinction between its own actions and those of those states, the USA has identified selected states as ‘sponsors’ of international terrorism – notably Iran, Syria and North Korea.

In both cases, non-state and state, ‘terrorism’ functions as what Münkler (2005) calls a ‘term of exclusion’: its use is intended to exclude specific acts of political violence from the sphere of political legitimacy. It follows that the public attribution of the term depends on the successful mobilization of IMAGINATIVE GEOGRAPHIES that deny legitimacy (even humanity) to those who perpetrate such acts of violence (Coleman, 2004). But terrorism is itself deeply invested in public acknowledgement: it seeks to spread fear among a much wider group than those who are its immediate, physical objects of attack. It is thus a communicative strategy: ‘Terrorism is a form of warfare in which combat with weapons functions as a drive wheel for the real combat with images . . . The most important feature of the recent wave of international terrorism is this combination of violence with media presentation’ (Münkler, 2005, pp. 111–12; see also RETORT, 2005). Hannah (2006b, p. 627) argues that fear has become such a powerful international weapon in our late-modern world because the threat of indiscriminate, indeterminate violence at once ‘acknowledges and feeds off the modern biopolitical responsibility of states’ to protect the welfare of their own populations: in short, terrorism is now a biopolitical strategy (see BIOPOLITICS, BIOPower).

Compared to mid-twentieth-century terrorism, the terrorist organizations that Münkler, Hannah and others have in mind have been able to launch far more destructive attacks, to act across far greater distances and to make far larger political demands. The 2005 Human security report calculated that ‘significant’ international terrorist attacks increased from seventeen in 1987 to more than 170 in 2003, with a similarly clear, if uneven, upward trend in numbers killed and wounded (but see below). Terrorism continued at other scales too, and local and regional terrorist campaigns continued to kill and maim victims around the world: people in AFRICA, ASIA, EUROPE and South America had been living with terrorism long before 11 September 2001, and domestic terrorism in the USA also plainly pre-dates 9/11 (Nunn, 2007). But as in many other fields, the closest analytical engagement of HUMAN GEOGRAPHY with terrorism was prompted by the extraordinary reach of al-Qaeda’s attacks on the World Trade Center and the Pentagon on 9/11, and subsequent attacks by al-Qaeda and its affiliates around the world (see figure). Three geographical responses can be distinguished:

(1) A more or less ‘popular’ GEOGRAPHICAL IMAGINARY cast those responsible for terrorist attacks outside any space of reason, so that to try to explain their actions was to exonerate them. No cause could justify such violence: the only response to barbarians hammering at the gates of CIVILIZATION was to meet their violence with greater violence. The cry was taken up by others who dismissed any opposition to the enlarged powers of the security state as itself a form of terrorism, and who enlisted the RHETORIC of the ‘war on terror’ as a means of legitimizing and intensifying the apparatus of repression. At its worst, this slid into an overt RACISM that fanned the flames of hostility to Arabs and Muslims in North America and Europe. This geographical imaginary conjured up a series of ‘wild spaces’, ‘their’ spaces where deviant others supposedly scurried away in the interstices and beyond the bounds of ‘our’ spaces (cf. Coleman, 2004; Gregory, 2004b).

(2) An ‘expert’ or ‘managerial’ response drew on geographical technologies (that were also political technologies) to profile, predict and manage the threat of terrorism as an enduring mode of late-modern government heavily invested in logics of SECURITY. The emphasis was on geographies of RISK assessment, on geospatial data management and modelling, and on the vulnerability of biophysical and built environments to terrorist attack (Cutter, Richardson and Wilbanks, 2003; see also Sui, 2008). This geographical imaginary worked to transform ‘our’ spaces into ‘safe spaces’: the domain of HOMELAND security (cf. Kaplan, 2003).

(3) A more critical response was to map the connections between ‘their’ spaces and ‘our’ spaces, and to unsettle the partitions between them. This involved explorations of the changing political and theological ideologies of terrorist organizations, which often involved locating potential targets within distinctive geographical imaginaries (Hobbs, 2005); analyses of the relations between material conditions, recruitment zones...
and the locations of terrorist attacks (Enders and Sandler, 2006; Simons and Tucker, 2007; Watts, 2007); reconstructions of the fluid and fractured networks through which regional and transnational terrorist groups are organized (Ettlinger and Bosco, 2004; Hastings, 2008), including investigations of the remittance networks that have been used to scapegoat potential sources of terrorist finance (de Goede, 2003, 2007; Amoore and de Goede, 2008); and examinations of the effects of counter-terrorist strategies on the representation, built form and everyday life of cities (Coaffee, 2004; Graham, 2006; Gray and Wyly, 2007; Katz, 2007). These contributions are closely connected – material conditions shape but do not determine terrorist networks, for example, while transactions monitoring infiltrates multiple spheres of everyday life – and intersect with more general critiques of the ‘war on terror’ and its extensions (e.g. Gregory, 2004b).

The most recent Human security brief (2007) argues that the global incidence of terrorism has dramatically declined since 2003. Other reports and databases suggest the opposite, but the authors of the Brief claim that this is in large measure a result of their inconsistent definition of ‘terrorism’. While those other surveys count as victims of terrorism large numbers of civilians killed by non-state actors in Iraq’s civil war, they exclude large numbers of civilians killed by non-state actors in sub-Saharan Africa’s civil wars (so-called ‘new wars’). They trace this back to the US State Department, which identifies ‘foreign terrorist organisations’ as those that threaten the security of US citizens or the national security of the USA. This dispute focuses attention on the controversy identified in the first paragraph, and on the vexed distinctions between (for example) terrorism and insurgency. These are innately contested terms precisely because they are performative: naming political violence in these and other ways has acutely real consequences for recruitment and support, legitimation and response. Coleman (2004); Flint (2003b); Gregory and Pred (2007).

text The term ‘text’ is used in HUMAN GEOGRAPHY in both its literal sense and also in a metaphorical sense, but the boundaries between the two usages are far from clear-cut.
Like all academic disciplines, human geography involves the interpretation of texts, understood as a corpus of written or printed material: first-order texts such as census records, diaries and transcriptions (conventionally called ‘sources’ – but this is misleading, since they are complex transcriptions and codings, whose origins lie elsewhere, and they are as often as not sedimentations of multiple, sometimes contradictory layers of meanings); and second-order texts (articles, monographs, dictionaries) that offer competing interpretations of those interpretations. This may seem commonplace, but it is not: ‘reading’ and ‘writing’ are not often included in discussions of methodology, yet they are central to the practice of geographical enquiry. They also have their own geographies, and Livingstone (2005a) has argued for an historical geography of textual circulation and interpretation. Influenced by actor-network theory, he describes written texts as ‘immutable mobiles’, which means that ‘knowledge does not move around the world as an immaterial entity’. Livingstone argues that the production and reception of texts are practices that take place in material spaces, and that geographers should attend to the geographical conditions of the engagement between texts and readers that transform interpretations and exclude as well as include audiences. In another sense, of course, this makes texts highly mutable mobiles: they are constantly subject to new interpretations and produce new effects (Ogborn, 2007).

These ideas have been extended still further to treat all productions of material culture as texts, including maps and landscapes. This work has been influenced by post-structuralism and sees cultural productions as unstable practices of meaning-making. Attention is focused on a multiplicity of competing meanings: hence ambiguity, volatility and a politics of interpretation. The core argument is that the principal characteristics of written discourse also describe social life: meaning in written texts is concretized through inscription, so social practices are concretized in the material landscape; as authors’ intentions and the reception of texts often fail to coincide, so social practices become detached from the consciousness of agents whose collective actions constitute such practices; written texts are reinterpreted under changing circumstances just as social events are continually reinterpreted; and as the meaning of written texts is unstable and dependent on interpretations of readers, so social action and institutions are open to a multiplicity of interpretations.

Post-structuralism has had a considerable influence on the reading of maps as texts (Harley, 1989; see cartography, history of), but readings of landscape as text have a more complex genealogy (Duncan and Duncan, 1988). Although cultural geographers have long regarded landscapes as palimpsests of culture–nature interactions to be read by specialists, notably themselves, many of those who have adopted the metaphor of landscape as text have eschewed the role of the ‘expert decoder’ in favour of an ostensibly reciprocal approach to landscape interpretation that moves in a hermeneutic circle. A key influence here has been the recovery of multiple layers of meaning through the thick description of American anthropologist Clifford Geertz (1926–2006) rather than their destabilization through the deconstruction of Derrida. Geertz’s hermeneutic-ethnographic approach to culture as text has guided the recovery of multiple readings proffered not by experts on the history of a generic landscape type but, instead, constructed by people who inhabit a particular landscape and who mobilize different readings as part of a politics that is central to its lively production and transformation (Duncan, 1990). And yet the recovery, reproduction and transmission of those constructions and contestations for a wider public audience is hardly the work of non-experts: not only do ‘first-order’ and ‘second-order’ texts bleed into one another, but the composite textualizations provided by Geertz may be read as the articulations of ‘an invisible voice of authority who declares what the you-transformed-to-a-they experience’ (Crapanzo, 1986, p. 74; see also Gregory, 1994, pp. 147–8).

Many geographers have questioned the usefulness of the text metaphor altogether, arguing that it leads to an over-emphasis on communication, intentionality and the discursive rather than the material or unintended (cf. non-representational theory). Defenders of the metaphor respond by arguing that cultural productions with text-like qualities (such as landscapes) are heterogeneous, material realities that are mutually constitutive with reading practices and interact with other non-human processes. It is also argued that landscapes are normally read inattentively or subconsciously, so that the norms and values that shape the landscape become naturalized and unconsciously absorbed. There are further differences of opinion on the degree of fluidity or stability of cultural practices and productions, and on the extent to which
interpretations are constrained by discourses. However, an expansive definition of text need not assume in advance of empirical investigation any particular degree of stability, instability or constraint. Fluidity versus stability is a matter of emphasis, not an either/or question.

Barnes and Duncan (1991); Duncan (1990); Ogborn (2007).

textuality In many versions of POST-STRUC- TURALISM, ‘textuality’ refers to the expansion of the term ‘TEXT’ to include cultural practices and material productions such as architectural forms and LANDSCAPES that may be read for meaning, connotation and contestation (cf. Barnes and Duncan, 1991; Duncan and Duncan, 1998). Such meanings are regarded as inherently unstable and incessantly recontextualized so that defined in this way textuality is indecidability. To investigate the textuality of the world is to investigate the PERFORMATIVITY of DISCOURSE: the ways in which meanings and objects are produced, contested, negotiated and reiterated. To view the world textually is also to see cultural productions as becoming detached from their authors and reinterpreted and recontextualized by interpreters as their relations to those productions change in often complex and unexpected ways. A textual approach thus brings into play indeterminacy, and involves both the denial of an mediated access to the world and a critical questioning of notions of authenticity and ESSENTIALISM. It focuses attention on the relations between texts and between their multiple contexts of production, reception and reinterpretation: on the play of INTERTEXTUALITY through which texts draw on other texts which in turn draw on other texts...

Textuality is sometimes seen to be compromised by the danger of textualism. This concern has two proximate sources. First, Said’s critique of ORIENTALISM has been immensely influential in HUMAN GEOGRAPHY, not least in expanding and ‘worlding’ texts, and asking what these cultural productions – these ‘doings’ – do in the world. Said uses the term ‘textuality’ in an opposite way to that described above, however, to disparage an over-emphasis on the mechanics of the text at the expense of the mechanics of the material world outside the text (cf. Smith and Katz, 1993). Second, Derrida’s famous remark that ‘there is nothing outside the text’ has often been used to accuse him of precisely this sort of textualism. To the contrary, however, Derrida’s point was that there can be no pre-discursive, non-contextual and non-intertextual understanding of the world: context is vital to his method of reading texts (see DECONSTRUCTION). Worries about textualism are real enough, and serious questions have been raised in human geography about the limits of the text METAPHOR and the privileges that it smuggles in to critical enquiry through its focus on cognition, meaning and interpretation (see NON-REPRESENTATIONAL THEORY).

theory The term ‘theory’ is used in various senses in the HUMANITIES and social sciences. At its broadest, theory can be understood as any set of statements and propositions used in explanation or interpretation. From the perspective of various versions of POSITIVISM, theory is subordinated to the tribunal of empirical validation – theories generate HYPOTHESES that are tested against evidence, with the aim of generating general laws. In this tradition, the value of a theory lies in its predictive ability and explanatory power. In geography, this notion of theory was associated with the QUANTITATIVE REVOLUTION, and was distinguished by the attempt to develop uniquely GEOGRAPHICAL THEORIES as the hallmark of a distinctively SPATIAL SCIENCE. The development of various post-positivist approaches has led to a shift in the meaning of theory in the discipline. These approaches all share the view that there can be no theory-neutral observation, and that the validation of any theoretical proposition is underdetermined by empirical evidence. Rather, theories are viewed as at least partly constitutive of the objects of empirical study (cf. DISCOURSE). This leads towards forms of GROUNDED THEORY, wherein empirical observation, concrete analysis and abstraction are combined in ongoing dialogue with one another (Sayer, 1992 [1984]).

Since the 1980s, there has been a veritable explosion of theory in HUMAN GEOGRAPHY. Graff (1992, p. 53) argues that theory breaks out in disciplines when ‘what was once silently agreed to in a community becomes disputed, forcing its members to formulate and defend assumptions that they previously did not even have to be aware of’. This idea of theory ‘breaking out’ is particularly pertinent to the increasing presence of cultural theory in human geography (see CULTURAL TURN). This is both a mark of heightened division within the discipline around methods and objects of
research, but also of an opening out to other disciplines. The interdisciplinary or even post-disciplinary nature of the theory circulating through human geography has become increasingly evident in the past two decades: if in the 1980s the agenda of Marxist-inflected human geography focused on the spatialization of social theory, since the 1990s the heightened geographical imagination of other disciplines has generated original contributions to the theorization of traditional topics such as landscape, place, space and scale (Gregory, 1994).

This pluralization of the sources of theory has also been associated with increasing attention to the politics of theory. From within geography, the growth of post-positivist approaches was closely associated with Harvey’s (1973) distinction between revolutionary, counter-revolutionary and status-quo theories. Geographers have also used Habermas’ (1987a) analysis of the different forms of human interest sustained by distinct types of theoretical knowledge, with its explicit argument that ‘critical theory’ best serves the causes of human emancipation (see Critical Theory). Human geographers’ treatment of the relationship between theory and politics has, however, developed beyond this idea that some theories harbour inherent political virtues in themselves, towards a more reflexive focus upon the forms of authority embedded in the practices of ‘doing’ theory. Three related issues have attracted attention:

(1) Geographers have been sensitive to the phenomenon of travelling theory. A great deal of theory now circulating in geography has been ‘imported’ from other disciplines, and this in turn allows geographers to talk across sub-disciplinary divisions and out to other scholars. But this raises contentions questions about expertise, competence and the external validation of positions staked internally within the discipline. Theory also has a real geography of its own. For example, most theory in the humanities and social sciences is actually produced and published in the USA, and more broadly in ‘the West’ (Barnett and Low, 1996). Other parts of the world are often not accorded value as sources of theoretical insight, being relegated to the status of sites for empirical investigation. This raises the challenge of ‘learning from other regions’, where this refers to the acknowledgement of versions of theoretical work belonging to traditions beyond the confines of Western Europe and North America (Slater, 1992: see also ethnocentrism; eurocentrism; situated knowledge).

(2) Building on this first issue, there is a set of concerns about the types of interpersonal authority embedded in the prevalent modes of theoretical commentary in human geography. Theory, and not least cultural theory, is associated with forms of mastery that construct patterns of closure, emulation and influence that belie overt claims to political radicalism (cf. masculinism). Feminist writers have been particularly creative in developing new styles of theoretical writing that challenge these prevalent forms of academic reasoning (Katz, 1996: see also minor theory).

(3) In its self-consciously ‘critical’ forms in particular, theory is often assumed as a tool for exposing the contingent, constructed qualities of phenomena, as an instrument for debunking ideologies, mythologies and misrepresentations. In turn, theory is often assumed to be an essential aspect of any practical politics of radical social transformation. This is indicative of a deeply rooted ‘scholastic disposition’, whereby it is assumed that the detached insights accorded to sceptical academics provide a privileged entry-point for changing the motivations of ordinary people and the mechanics of worldly processes (Bourdieu, 2000). In response to this sort of scholastic attitude, Thrift (1999a, p. 304) recommends what he calls modest theory, understood as a ‘practical means of going on rather than something concerned with enabling us to see, contemplatively, the supposedly true nature of what something is’. Non-representational theory is meant to exemplify this notion of modest theoretical practice. However, its characteristic modes of presentation reiterate many of the rhetorical devices of distinction and exclusion associated with conventional forms of grand theory.

GEOGRAPHY remains a discipline deeply suspicious of theory, heavily invested as it is in notions such as ‘the field’, ‘empirical work’, ‘politics’ and ‘practice’. These notions are often invoked to sustain their own forms of authority, closure and exclusion. Debates about relevance in the discipline often take the form of arguments that there is too much theory
in geography, or too much of the wrong sort of theory. When faced with such arguments, it is always best to remember a simple dictum: ‘Hostility to theory usually means opposition to other people’s theories and an oblivion to one’s own’ (Eagleton 1983, p. viii). CB

**thick description** A term coined by the philosopher Gilbert Ryle (1971) and introduced into the humanities and social sciences by the anthropologist Clifford Geertz (1973b), ‘thick description’ refers to rich ethnographic descriptions based on intensive investigations of informants’ actions and their interpretations of their own practices placed within their cultural context. It is an intrinsically hermeneutic method that recovers and represents the researcher’s interpretation of informants’ interpretations.

Thick description is contrasted with ‘thin description’ based on the tenets of behaviourism, where a detailed description of the informants’ contextualized meaning systems is considered unnecessary (cf. BEHAVIOURAL GEOGRAPHY). Thick description is usually produced through grounded, long-term ethnographic research, based on (principally) qualitative methods applied to small-scale settings (see ETHNOGRAPHY), but it has also been used in intimate, archive-based historical research with considerable success (Darnton, 1985). Thick description is not simply about collecting details: it is about uncovering the depth of multiple, intersecting webs of meaning within which individual actors understand their own actions. Geertz conceives of individual behaviour as informed by complex, situated conceptual structures that are culturally and historically produced. As such, behavior is best interrogated contextually to reveal the systematic quality of ‘cultural patterning’ that are ‘extra-personal institutionalized guides for behavior’. These are emphatically not ‘essences’ of broader cultures studied in a microcosm, the ‘Jonesville is America writ small’ model that Geertz dismisses as ‘palpable nonsense’. An important implication of this cultural patterning is that social life has a public, text-like quality to which all who share in a culture interpret, negotiate and contribute. It then follows that ethnographers and other like-minded scholars must ‘read over the shoulder’ of those whose culture they study. Cultures as meaning systems intertextually infuse all forms of social practice, and Geertz also saw cultural texts as literary texts to be looked at critically and not just through. Such a textual orientation (see TEXTUALITY) made him an important early figure in the cultural turn across the social sciences, and in opening up conversations between the social sciences and the humanities. Geertz’s influence spread well beyond anthropology into the work of the New Historians in literary studies and the work of the New Cultural Historians (see HISTORICISM). In CULTURAL GEOGRAPHY, his writings influenced Duncan’s (2004) interpretation of the symbolic/political system of the Kandyan kingdom in Sri Lanka.

Geertz’s ‘cultural patterning’ perspective has been critiqued in anthropology for allowing little space for the inner, private, non-cultural components of the self. Thus while Geertz was instrumental in shifting anthropology from a focus on social structure to the interpretation of meanings, his analysis remains somewhat structural. However, this is not to say his approach is at all reductionist or determinist. He rejects tight arguments and conceptualizations ‘purified of the material complexity in which they are located’. He sees structures of meaning as historically specific, fluid, fragmentary, negotiated and situational. The researcher’s interpretations are interpretations of the interpretations of others and thus are always open to contestation and deeper grounding in ongoing, changing cultural meanings systems. That said, among human geographers the textual conception of culture that underpins Geertz’s project has been critiqued by Gregory (1994, pp. 148–8) for its structural stasis and by Rose (2006) for its emphasis on representation, meanings and consciousness (cf. NON-REPRESENTATIONAL THEORY). JSD

**third space** A space produced by processes that exceed the forms of knowledge that divide the world into binary oppositions. Bhabha (1990b) argues that third space is a consequence of HYBRIDITY, suggesting that certain forms of post-colonial knowledges challenge the division of the world into ‘the west and the rest’ by producing third spaces in which new IDENTITIES can be enacted (see POST-COLONIALISM). For Bhabha, third space is a position from which it may be possible ‘to elude the politics of polarity and emerge as others of ourselves’ (1994, p. 39). Some
Third World  A term first used by French economist Alfred Sauvy in 1952 to locate a group of countries not formally aligned with the USA or the Soviet Union in the Cold War, and not always attached to capitalism or socialism as defining economic models. The first Prime Minister of independent India, Jawaharlal Nehru, was a key figure in both these projects. He played a leading role in the Non-Aligned Movement, whose inaugural meetings were held at Bandung in Indonesia in 1955. He also called for a ‘third way’ of promoting economic development – that of planning under a system of democratic socialism – long before ideas of a Third Way were popularized by US President Bill Clinton and British Prime Minister Tony Blair.

The initial concept of a Third World as a new Third Estate has been consistently reworked since its introduction into public discourse (Mintz, 1976; Pletsch, 1981). Many of its initially positive connotations were diminished in the 1960s. They were replaced by an idea of the Third World that located a group of countries in Asia, Africa and Latin America in terms of certain presumed absences. These countries were lacking in infrastructure, lacking in education and healthcare systems, lacking in fiscal resources or foreign exchange, lacking in skills and so on. As such, they needed to be mended, both by their own governments and by donor agencies and military personnel from the First and Second Worlds.

This conception of the Third World has fallen from favour over the past thirty years. Peter Bauer, an economist associated with the counter-revolution in development theory and policy, argued consistently in the 1970s that the giving and receiving of foreign aid invented the Third World. Worse, in his view, it turned the Third World into a supplicant (Bauer, 1974). It deprived African and Asian countries of the motivation to pull their own peoples out of poverty by means of market-led economic growth. In the 1990s this argument was given fresh legs by Arturo Escobar, one of the leading theorists of post-development. Escobar (1995) argued that the Third World had been invented by American aid programmes and Cold War geopolitics. It had been infantilized and pathologized by a ‘discourse of development’ that ‘discovered mass poverty’ throughout this apparently uniform geographical and social space. Large parts of it had also been turned into battlefields in the struggle between the USA and the Soviet Union (literally so in various proxy wars).

Escobar recognizes that some Third World countries have turned this form of identification to their own advantage, not least through the politics of Third Worldism. This is a common strategy of subaltern social groups and it found expression in the 1970s in Southern demands for a New International Economic Order. Escobar, however, is more inclined to think outside the confines of the ‘Third World/Third Worldism’ categories. In his view, it is important to create new spaces for social and economic action in what he calls ‘the less economically accomplished countries’. Others have suggested that the Third World should be renamed as the Two-Thirds World, and that it should not be restricted to the ex-colonial
world. If poverty is a defining feature of the (Two-)Third(s) – or ‘majority’ - World, it is to be found in countries across the globe and not just in the global SOUTH.

Tiebout model An argument for dividing an area among local government units that compete for land users through the range of ‘service-taxation packages’ offered (see COMPETITIVE ADVANTAGE). Charles Tiebout (1924–68: see Tiebout, 1956) argued that inability to respond to the diversity of demands for PUBLIC GOODS and SERVICES (and differing willingness to pay for them) generated by a heterogeneous population makes large local governments inefficient. Fragmentation of local government within urban areas is more efficient: each unit tailors the services offered and its taxation demands to a particular population sector and people choose which they prefer (cf. FISCAL MIGRATION). The model assumes full information about the range of ‘packages’ on offer and no mobility constraints – which considerably limit its empirical applicability. Fragmented local government systems are frequently manipulated by the affluent and powerful to create ‘tax havens’ from which, however, the less well-off are excluded (cf. ZONING).

time The concept of time has been relegated to an implied and secondary status in discourses about the PHILOSOPHY of GEOGRAPHY ever since the path-breaking work of Immanuel Kant in the second half of the eighteenth century. Arguing that both time and SPACE are distinct and necessary a priori notions, rather than substances, for any understanding of human experience, Kant paved the way for the creation of separate academic disciplines addressing spatial rather than temporal questions in the nineteenth century. Advances in many of the SCIENCES during the twentieth century questioned both the validity and the wisdom of a categorical distinction between space and time, however, notably the work on ‘spacetime’ by Hermann Minkowski (1864–1909) and Albert Einstein (1879-1955), and on ‘lived time’ by Jean Piaget (1896-1980), and paved the way for more relativist and relational accounts. Although in practice the Kantian separation between time and space advocated by Hartshorne (1939) never hindered concrete geographical research (see HISTORICAL GEOGRAPHY), a theoretical attempt to reconcile both was not launched until the 1970s and early 1980s as ‘TIME-GEOGRAPHY’. Emanating chiefly from Sweden but gaining wide acceptance especially in Anglophone HUMAN GEOGRAPHY (Carlstein, Parkes and Thrift, 1978), time-geography originated in the work of Torsten Hägerstrand (1970). At its roots is the realization that the spatio-temporal choreography of individual paths through EVERYDAY LIFE is constrained in a variety of forms; their VISUALIZATION becomes a first heuristic step towards dissecting concrete POWER relations operating within society. The broad appeal of time-geography can be measured by its incorporation into the framework of STRUCTURATION THEORY (Pred, 1984).

The interrelationship between space and time can be seen in many cultural practices. It was clearly demonstrated by the establishment of Greenwich Mean Time (GMT) in 1675, which set a marker for many subsequent geographical designations and culminated in the binding arbitration of global time zones in 1884. The fact that such a system, which was both locally and globally applicable, was centrally involved in colonial conquests, the rise of CAPITALISM or in the gendering of social relations, is now well documented (Adam, 2006). Knowing where one was at any one given time was a prerequisite to ordering, hierarchically structuring and eventually commodifying daily routines, flows of goods and capital and something as mundane as travelling from A to B.

The standardization of time is connected with the rise of railroad technologies in the nineteenth century. At the beginning of that century time was still measured locally, and thus more accurately, but by the beginning of the twentieth century most NATIONS had adopted some national time or time zones (although calendars remain mired in cultural traditions to this day). Structurally akin to similar attempts to de-localize or de-nationalize spatial measurements – to wit, the standardization of the metre in 1889 – such developments ultimately paved the way for the all but universal adoption of ‘clocked time’, which has since held sway over modern experiences, and has perhaps most poignantly been criticized by Charlie Chaplin in his 1936 film Modern times (Glennie and Thrift, 2005, 2009: see also MODERNITY). However, GLOBALIZATION, and the changing geographies brought about by
the spread of the Internet, have both altered the geographical experience of time and arguably led to new geographical realities. To some extent irrespective of geographical location, the experience of simultaneity may be shared by people living in most ‘core’ urban areas of the world – and is used by stock market traders on a 24/7 basis to further their economic gains.

time-geography An approach to HUMAN GEOGRAPHY treating TIME and SPACE as RESOURCES directly involved in the constitution of social life. It was developed by the Swedish geographer Torsten Hägerstrand and his associates at the University of Lund during the 1960s and 1970s (Hägerstrand and Lenntorp, 1974). Time-geography is not supposed to be a theory, but rather an ONTOLOGICAL contribution focusing on how different phenomena are mutually modified because they coexist in time and space. As such, Hägerstrand attributed a certain NATURALISM to the approach, characterizing it as a ‘topoecology’ designated to grasp a society–nature–technology constellation. He acknowledged an affinity with PHENOMENOLOGY but still argued for a physical approach to the social world (Hägerstrand, 1982).

Time-geography was developed in relation to empirical work and an intensive involvement in Swedish planning. Its basic element is connections between continuous trajectories of individual entities in time–space. From these, descriptive concepts were developed, such as paths, stations, projects, prisms, time–space bundles and time–space domains. They constitute a world view on the human condition stating that everybody is subject to confinement in time–space within the limits formed by the bounded capacity of individuals to engage in more than one task at a time, by the speeds at which it is possible to move and assemble individuals, tools and materials, and by regulations of access and modes of conduct within domains of local order. Most well-known is the translation of this view into a non-linguistic notation system representing possible configurations in time–space (see figure). It proved a useful tool in planning and was heavily used also in early FEMINIST GEOGRAPHIES of time–space constraints in women’s everyday life.

While time-geography's representational potential is widely acknowledged, its metaphysical basis has been severely criticised. Two streams of criticism have prevailed. One points to a problematic relationship to SOCIAL THEORY, and especially how the naturalism or 'physicalism' of the approach leads to a defective conception of human thought-and-action and erodes the possibility of developing a social understanding of time–space (Gregory, 1985). The other line of criticism charges time-geography with MASCU琳INISM (Rose, 1993). It regards time-geography as a visual strategy that renders space objective and transparent (see VISION AND VISUALITY). Furthermore, the moving bodies of time-geography are seen as 'imaginary bodies'; 'universal' and deprived of social and cultural markings of 'RACE', 'GENDER' and 'SEXUALITY'.

Some geographers have sought to develop more socialized versions of time-geography. In the 1980s, these attempts often relied upon a convergence with STRUCTURATION THEORY. Perhaps the most prominent of these attempts came from Allan Pred (e.g. 1986), who studied agrarian and urban change in nineteenth-century Sweden as an interaction between social restructuring, everyday routines and the production of meaning. Since the 1980s interest in time-geography has been renewed on two levels. First, its descriptive capacity has been developed through GIS-based technologies and 3-D VISUALIZATIONS of human activity patterns. Second, Hägerstrand's emphasis on encountering, events

time–space compression An increase in the speed of social life and a diminution in the constraining effects of distance on human activities. Processes of this kind have a long and varied history, but when David Harvey (1989b) first proposed the term, his primary purpose was to designate the product of what Marx saw as the compulsion to ‘annihilate space by time’ under capitalism. Marx famously described capitalist modernity as a world in which ‘all that is solid melts into air’, but Harvey showed how this extraordinary volatility – the accelerating rhythm of social change – is connected through the restless expansion of capital accumulation to far-reaching transformations in the structures of an increasingly global space-economy. Harvey explained that he deliberately used the word ‘compression’ because ‘a strong case can be made that the history of capitalism has been characterized by speed-up in the pace of life, while so overcoming barriers that the world sometimes seems to collapse in upon us’. These are ‘processes that so revolutionize the objective qualities of space and time that we are forced to alter, sometimes in quite radical ways, how we represent the world to ourselves’. Harvey thus intended the concept to have an experiential dimension that is missing from related concepts such as time-space convergence and time-space dislocation. He paid particular attention to the ways in which time–space compression dislocates the modern habitus that gives social life its precarious coherence: implicated in a crisis of representation (‘how we represent the world to ourselves’), the consequences of time–space compression are supposed to be disturbing, even threatening; time–space compression is a ‘maelstrom’ and a ‘tiger’ that induces ‘foreboding’, ‘shock’, a ‘sense of collapse’ and even ‘terror’ that, at the limit, translates into a ‘crisis of identity’ (Harvey, 1989b, 1990, 1996).

Harvey was radicalizing an argument proposed by the conservative critic Daniel Bell in The cultural contradictions of capitalism (1978). In Bell’s view, ‘physical distance’ was ‘compressed’ by new systems of transportation and communication at the turn of the nineteenth and twentieth centuries, and what he called ‘aesthetic distance’ was in its turn compressed by a corresponding stress on ‘immediacy, impact, sensation and simultaneity’ that was characteristic of the cultural formations of modernism. Harvey took this account further by:

- wiring cultural crises of representation to basal crises of capital accumulation (see crisis); and
- reading the cultural formations of post-modernism as symptoms of the heightened intensity of a new round of time–space compression produced by a regime of flexible accumulation at the close of the twentieth century (see Gregory, 1994, pp. 406–14).

Harvey’s theses have been subjected to both critique and development:

(1) Some feminist geographers have been sceptical of Harvey’s view of time–space compression as threatening, and seen his ‘cartographic anxiety’ as symptomatic of a challenge to the confident masculinism of mainstream theorizing (Deutsche, 1996a) (cf. cartographic reason). This has fed into a recognition of the multiple registers through which time–space compression is socially differentiated, and Massey (1993) proposed a comprehensive grid of agency and affect, position and power that she called the ‘power-geometry of time-space compression’ (cf. Bridge, 1997).

(2) These objections intersected with alternative theorizations of place. Some critics complained that the containing metaphor of time–space compression represented place as a bounded site whose ‘essential identity’ is hollowed out by the powerful forces of capitalist globalization. To Gibson-Graham (2000a [1996]), this scenario enacts a ‘rape-script’ that ‘normalizes an act of non-reciprocal penetration’: all non-capitalist forms are construed as ‘sites of potential invasion, envelopment, accumulation’, victims awaiting their violation. This evidently militates against the very politics that Harvey is concerned to advance (but cf. Harvey, 1996, pp. 291–326). Others argued that the original metaphor distracted attention from the production of more open, so-called ‘global’ conceptions of place in which the intimate and the impersonal, the virtual and the corporeal, the near and the far are
reassembled in new constellations. In a parallel series of essays that centred on the technical transformations in the circulation of money that lie at the heart of Harvey’s theses, for example, Thrift (1997a) showed that ‘new forms of electronic detachment have produced new forms of social involvement’: that contemporary processes of time–space compression still depend on the intimacy of interpersonal contact.

These contributions emphasize that time–space compression is spatially differentiated. Harvey’s original account of ‘the shrinking world’ focused on the global north and was insensitive to the multiple and compound geographies of time–space compression, but since then he has provided more nuanced discussions that pay closer attention to the global south and to the politico-military carapace of contemporary accumulation by dispossession (Harvey, 2003b, 2005; cf. Agnew, 2001; see primitive accumulation). Harvey continues to emphasize the political economy of time–space compression, and while it is not necessary to accept Massey’s (1993, p. 60) characterization of this as an ‘economism’, time–space compression does have other vital dimensions that are connected but cannot be reduced to the logics of capital. Late-modern war emphasizes the enhanced power of military violence over time and space, for example, and the formation of transnational public spheres reveals the importance of global flows of images and information to the formation of network societies. All of these dimensions have their own hierarchies, margins and exclusions – hence the crucial importance of positionality (Sheppard, 2002) – and these variable topologies imply that time–space compression operates alongside processes of time–space expansion.

Agnew (2001); Harvey (1989b, chs 15–17).

time–space convergence A decrease in the friction of distance between places. As this definition suggests, the concept originated within spatial science, where it was first formulated by Douglas Janelle (1968). He defined the convergence rate between two locations as the average rate at which the time needed to travel between them decreases over time: the measure was supposed to be ‘mathematically analogous to velocity as defined by the physicist’.

Janelle (1969) attributed time–space convergence to technical change: ‘as a result of transport innovation, places approach each other in time–space’. Janelle showed that time–space convergence is usually discontinuous in time – convergence curves are typically jagged, corresponding to pulses of technical innovation – and uneven over space: ‘Any transport improvement will tend to be of greatest advantage to the highest-ordered centre that it connects’ (Janelle, 1968). Forer (1974) noted that the converse is also true – that time–space convergence is partly a function of the hierarchical structure of the settlement system – so that Janelle’s model of ‘spatial reorganization’ entailed a double movement in which ‘places define spaces’ and spaces in turn progressively ‘redefine’ places.

Other geographers distinguished distance-convergence from cost-convergence and identified a pervasive tendency for the friction of distance to decrease under the sign of modernity. Since the friction of distance is a fundamental postulate of classical central place theory, diffusion theory and location theory it is, after all, what makes the identification of spatial patterns possible – time–space convergence was supposed to ‘scramble’ and ‘play havoc’ with these standard geometric models (Falk and Abler, 1980). Time–space convergence was thus linked to a concept of plastic space: ‘a space defined by separation in time or cost terms, a space which the progressions and regressions of technology make one of continuous flux’ (Forer, 1978).

These were simple but suggestive ideas, yet Forer (1978) suggested that most contemporary geographers had paid little attention to them because they addressed ‘the larger canvas of economic history and the long-term development of society’. Ironically, however, it was precisely those links that turned out to be most important. Pred (1973) had already provided an imaginative reconstruction of the changing time-lags within the circulation of public information through major newspapers published on the eastern seaboard of the USA between 1790 and 1840. Although his studies mapped the geography of time–space convergence and its hierarchical structure, and made explicit reference to Janelle’s contributions, Pred was more interested in the
politico-economic and cultural implications of time–space convergence than in the geometric structures that preoccupied the original architects of the concept. For much the same reason, calibrations of time–space convergence are now more likely to be situated within the conceptual field of time–space compression that directly addresses such concerns.

time–space distanciation A term proposed by British sociologist Anthony Giddens to describe the ‘stretching’ of social systems across time and space. The concept played a central role in his critique of modern social theory and the development of his rival structuration theory. Giddens argued that conventional social theory was strongly influenced by forms of functionalism, which assumed that societies are coherent and bounded systems, and by models of social change that presumed that the basic structural dimensions of societies are internal to those systems. Time–space distanciation was intended to confound both claims: ‘The nexus of relations – political, economic or military – in which a society exists with others is usually integral to the very nature of that society and, indeed, to what “societies” are conceived to be’ (Giddens, 1981). Today this is a commonplace in most of human geography, though it has been developed in ways that have moved far from Giddens’ own formulations, but there are nonetheless affinities between time–space distanciation and concepts of time–space compression and time–space convergence. There are also two significant differences.

(1) ‘Time–space distanciation’ draws attention to the capacity for social life to extend over time as well as space in ways that are not limited to the contemplation of a
(2) Giddens offered an outline sketch of the historical trajectory of time–space distanciation that was also intended to be an analytical map of different types of society. In contrast, discussions of time–space compression have largely been limited to its role within contemporary capitalism, while time–space convergence is a purely formal concept concerned with calibrating convergence rather than examining its constitution within different societies.

Giddens claimed that tribal societies are characterized by low levels of time–space distanciation—the capacity for social memory is limited and most interactions are localized—and by little substantive distinction between ‘political’ and ‘economic’ power. With the emergence of class-divided societies such as those of European feudalism, the level of time–space distanciation increases, largely through the political powers extended to and through the state. The transition to the class societies of capitalism is achieved through the greater prominence of economic power, especially through industrialization, and is marked by much higher levels of time–space distanciation. In his early texts, Giddens (1984, 1985) emphasized the mobilization of systems of writing, recording and surveillance (modalities of ‘political power’) and systems of monetization and commodification (modalities of ‘economic power’), but in his later texts he became much more interested in the constitution of contemporary or ‘high’ modernity. There, Giddens (1990, 1991) distinguished between:

- expert systems, which ‘bracket time and space through deploying modes of technical knowledge which have validity independent of the practitioners and clients who make use of them’; and
- symbolic tokens, which are ‘media of exchange which have standard value and thus are interchangeable across a plurality of contexts’.

Together, these constituted abstract systems which, so Giddens argued, penetrate all aspects of everyday life and in so doing undermine local practices and local knowledges; they dissolve the ties that once held the conditions of daily life in place and recombine them across much larger expanses of space (cf. globalization).

Giddens’ argumentation-sketch has been subject to several criticisms. The most common objection is that it lacks sufficient historical and geographical specificity (cf. Harris, 1991). In treating space as a gap to be overcome, it represents space as a barrier to interaction—as a void to be transcended, incorporated and subjugated—and in doing so activates conventional conceptions of place and space (cf. contrapuntal geographies) and repeats the characteristic movement of Western master-narratives more generally to recover what eludes them as lacunae, margins, ‘blank spaces’ on the map. This intersects with sustained objections to the eurocentrism of Giddens’ formulations. The trajectory of time–space distanciation traces a move away from the immediate and the intimate, but this is an implausible view of non-modern societies and, as Giddens subsequently conceded, it also fails to recognize the continued importance of face-to-face interaction and intimacy in late modernity. Finally, time–space distanciation, like structuration theory more generally, privileges modalities of political and economic power and fails to explore the significance of the cultural formations that have been centrally involved in processes of globalization and the constitution of modernity.

time–space expansion A concept proposed as (1) the corollary and (2) the dual of time-space compression.

(1) Dodgshon (1998) proposed time–space expansion as the corollary of time–space compression. The modern world may be one of intensifying change and volatility, as Harvey’s (1989b) original account of time–space compression suggests, but this entails more than an emphasis on the transient, the fleeting, the ‘now’: for the modern science that powers many of those transformations has also produced a heightened awareness of the immensity of time and of human history. For the privileged, the modern world may be
increasingly frictionless, even ‘flat’ as global travel and communication increases, but in consequence ‘what was once thought to be an experience of the geographical world in its totality has been re-proportioned into what is simply local’. In sum, Dodgshon (1998, p. 117) insists, time–space compression means that ‘culturally, we are now more aware of time and space as dimensions that have extension’.

(2) In contrast, other writers treat time–space expansion as the dual of time–space compression. They recognize that power-geometry is highly variable, and in particular that the power to compress distance is also often the power to expand distance. The unidirectional logic of time–space compression requires distance to contract under the spasmodic compulsions of global capitalism to reduce circulation time, but images of ‘the shrinking world’ have become so powerful and pervasive that they can obscure the ways in which, for millions of people, the imperatives of globalization can force their world to expand in ways that threaten to become unbearable. Katz (2001a) draws on her experience in ‘Howa’, a village in Sudan, to argue that:

From the vantage point of capital, the world may be shrinking but, on the marooned grounds of Howa, it appeared to be getting bigger every day. After a gruelling decade and a half of structural adjustments and political upheaval in Sudan, people in Howa survived by maintaining a semblance of the patterns and practices of production that had long sustained them... But this was only viable now if carried out over an extended physical arena. The terrain of social production and reproduction had expanded from perhaps five kilometres in 1980 to two hundred kilometres by 1995, the distance men routinely travelled to participate in the charcoal trade. Time–space expansion also represented a transformation of the old constellation of activities that involved men’s long absences from the village. People still farmed (but also worked as agricultural laborers up to a hundred kilometres away), kept animals (by sending them out with relatives to distant pastures) and cut wood (but now in areas of the South targeted for deforestation as part of the northern government’s war effort). (Katz, 2001, p. 1224)

For Katz, therefore, ‘time–space expansion embraces, reworks and plays into the altered geographies of globalization’. Contemporary capitalism involves dialectical torsions of time–space compression and time–space expansion (see dialectic) that produce spirals of advantage and marginalization: ‘If in one way the known world expanded for people in Howa, in others their place in it receded as their village was increasingly marginalized’ (p. 1225).

Time–space expansion happens not only within a relative space punctuated by the differential geographies of time–space compression, however, but also through the proliferating partitions of an intrinsically colonial modernity. ‘If global capitalism is aggressively de-territorializing, moving ever outwards in a process of ceaseless expansion and furiously tearing down barriers to capital accumulation, then colonial modernity is intrinsically territorializing, forever installing partitions between “us” and “them”’ (Gregory, 2004a, p. 253). Those who live under military occupation (see occupation, military) know this very well, as they are caught in curfews or lockdowns and wait in line at checkpoints: time seems to stop, punctuated by one emergency after another, and the ordinary paths of everyday life are blocked or redirected. In occupied Palestine, for example, ‘as the illegal settlements are wired ever more tightly into Israel, Palestinians are made to undergo an intensified spasm of time-space expansion: families, friends and neighbours cut off from one another; farmers separated from their fields and their wells’ (Gregory, 2004c, p. 604). Those who try to flee the politico-economic deformations described by Katz and the politico-military oppressions described by Gregory are peculiarly vulnerable to the despair of time–space expansion. ‘The globe shrinks for those who own it,’ Bhabha (1992, p. 88) remarks, but ‘for the displaced or the dispossessed, the migrant or refugee, no distance is more awesome than the few feet across borders or frontiers’ (cf. Hyndman, 1997: see also migration; refugee).

topographic map A large- or intermediate-scale map describing the most important physical and cultural features of a place or region. Largely a product of national or provincial governments, topographic maps support national defence, economic development, environmental science and growth management as well as providing data for compiling less detailed, smaller-scale maps. Typically compiled from aerial photography, they use contour lines (see isoline) to describe the land surface and
abstract symbols to represent roads, railways, political boundaries and hydrographic features such as rivers, streams and lakes (Collier, Forrest and Pearson, 2003). Toponyms (place names and feature names) reflect local usage as well as government efforts to standardize spelling and nomenclature (Monmonier, 2006).

**Suggested reading**

**topography** The detailed study and description of a place as much as to the materiality of its features or landforms more generally. In recent years, topography has been mobilized as a research method, ‘to carry out a detailed examination of some part of the material world, defined at any scale from the body to the globe, in order to understand its salient features and their mutual and broader relationships’ (Katz, 2001, p. 1228). In this sense, it has been used in critical human geography to delineate the social production of localities as much as the knowledge about them, understanding both to be the contested outcomes of particular interests and actors. The intent is to discern the sedimented process of place-formation from the locality itself and in so doing, situate ‘places in their broader context and in relation to other areas and geographic scales’, thereby offering a means of understanding structure and process simultaneously (Katz, 2001, p. 1228). Just as topographic maps connect sites of equal elevation through contour lines, so too can particular relationships across localities be revealed and examined using topography. That is, the trace or effects of particular processes on various places can be demonstrated through this methodology to suggest their translocal bearing. This understanding led to the notion of ‘counter-topographies’, which are seen as a way to theorize the connectedness of disparate places by virtue of their relationship to a particular political-economic or social process, such as democratic inclusion, privatization or gentrification. Focusing on the de-skilling of young people, for instance, Katz (2001a) produced a counter-topography linking New York City and rural Sudan. The connections drawn are analytical rather than homogenizations.

Counter-topographies are concrete abstractions that offer a means of recognizing the historical and geographical specificities of particular places while also enabling the inference of their connections in relation to specific material social practices. The intent in linking different places analytically is to produce an alternative geographical and political imagination that might work translocally in the name of common interests (cf. Pratt, 2004; also contrapuntal geographies). The geographical imagination associated with topography as a method and the political possibilities of counter-topographies as concrete abstractions have been best realized by feminist geographers. Looking at political transformation in Mexico, Lise Nelson (2004) drew out a topographical analysis to examine the historical experiences of rural women engaging in regional and even national commerce, and the ways in which their engagements led to reconfigurations of their subjectivities along with the contours of their political practices. Her work demonstrates how ‘the shifting norms and practices of gender and citizenship’ in a single place both propel and are propelled by changing local–global dynamics. Telling far ‘more than a “local” story’, the renegotiations of subjectivity reveal as they alter the social relations of power and difference across scale (Nelson, 2004, pp. 180–2). Pratt and Yeoh (2003) use topography as a means of examining transnationalism with greater specificity and attentiveness to difference. Revealing the ‘multistranded connections transnational subjects make’ as they move across space and scale, they develop the notion of ‘comparative transnationalisms’, and theorize their diverse but interconnected manifestations on the ground (Pratt and Yeoh, 2003, p. 164).

Katz (2001); Nagar and Swarr (2005).

**topology** A field of mathematics studying the spatial properties of an object or network that remain true when that object is stretched. These include connectivity and adjacency. Imagine stretching a rubber band between two fingers. Likening the band to a vector line segment, then the start node (the one end) remains connected to the other despite the stretching. Treating the band as a polygon, the one side remains to the left of the other throughout. Topological encoding is useful in GIS for error trapping and spatial queries. Networks may be represented as graphs and analysed using graph theory.

**topophilia** A term coined by geographer Yi-Fu Tuan (1974, p. 4) to describe the
Tourism has been defined as ‘the affective bond between people and place’ (cf. Affect). Tuan argued that this bond varies in intensity among individuals and in its cultural expression, and suggested that such attachment can be based on aesthetic appreciation, MEMORY, pride of ownership or dependence on a place for one’s livelihood or security. Topophilia is not only a response to place, Tuan insisted, but also actively produces places for people. Its converse, topocide, was proposed by Porteous (1998) to describe the annihilation of those bonds and the places to which they are attached (cf. URBICIDE). Topophilia is closely associated with the HUMANISTIC GEOGRAPHY of the 1970s.

**tourism** Tourism has been defined as ‘the activities of persons traveling to and staying in places outside of their usual environment for not more than one consecutive year for leisure, business and other purposes’ (UN World Tourism Organization, 1994). This relational definition positions tourism as contrasted to other travel and leisure practices. Thus travel for pleasure without staying tends to be defined as LEISURE, whilst organized activities for pleasure at home tend to be called RECREATION. Travel without return is MIGRATION, whilst temporary travel leading to residence for work over a year is to be a sojourner. The utility of this definition is enabling the counting and mapping of tourist FLOWS – arrivals, stays and departures. However, this a very limited approach to tourism. First, as a typology of travel it tidies away a wealth of practices that elide the differences of these categories. Second, there are distinctions among tourists. Third, it fails to capture the dynamic of the relationship of tourists to the people and places that they visit.

The first problem is that the practices and organization of tourism exceed its categories. It may be the largest industry on the planet, but it is a very diffuse industry. Thus tourist attractions may also serve local populations – facilities that serve tourist needs (such as restaurants or hotels) may serve local needs as well. Amidst what tourists do, there are a wealth of different interests and activities. Thus much tourist time may well be pursuing ‘normal’ activities (such as child care, cleaning or cooking). Equally, the edges of what is tourism are very fuzzy, so that local people might approach their local environment for pleasure like a tourist. Meanwhile, tourism has been said to develop from, and as a secular form of, pilgrimage, leaving questions over whether we would count these spiritual practices as ‘tourism’ or whether we would deny any spiritual dimensions to any forms of tourism.

The second problem is that the general definition obscures differing types of tourism. One recurrent response has been to produce typologies of tourists usually defined by their motivation for travel. Popular distinctions among tourists often start by dividing them in terms of a hierarchy of serious mindedness, where the explorer charts the unknown (see EXPLORATION) and the traveller seeks to encounter difference, whilst the tourist follows the beaten track. The distinctions between these cultures of travel are social ones that are about status and cultural values.

John Urry (2002) suggests contrasting romantic and collective cultures of tourism. The latter is that which celebrates togetherness in visiting, which focuses on enjoyment and activities amongst and between visitors rather than between visitors and the environment. The former is that of the traveller, who seeks an individual encounter with the place visited – with direct contact with the locale and perhaps locals. It defines itself in opposition to the collective gaze – and in doing so sows the seeds of its own self-destruction. For once a site is found and becomes popular, is laid out in guidebooks, and develops kiosks or stalls, then it loses its appeal. The result is an expanding structure, always looking over the next hill or to the next island for the ‘untouched’ valley, ‘pristine’ beach or ‘authentic’ locals. This lays out tourism as what MacCannell, in his influential 1976 book *The tourist*, saw as a quest to encounter the authentically different other. However, Urry’s division makes clear that this is only one set of desires or motivations for tourism. He himself favours a definition that frames tourism in terms of a time and place out of the ordinary.

The notion of an ‘extraordinary’ time and place has been used to unpack the third issue of the dynamic of tourists and the places that they visit. Tourism as a secular kind of pilgrimage might be seen as a material semiotic process that ‘sacralizes’ places. In this process, various signifiers mark out sites as noteworthy to the ‘tourist gaze’ (Urry, 1990). These signifiers can be guidebooks, postcards, travel books, brochures, adverts and the like. These help script notions of the destination and can be seen as ‘linguistic agents of touristic social control’ (Dann, 1999, p. 163). Guidebooks do not just describe places, but set normative agendas of what ought to be seen. They
emphasize, construct and delimit a geography of significant sites. Visiting these places may be part of accumulating cultural capital. The scripting may also rework the histories and geographies of places. As Jane Desmond notes, ‘tourism is not just an aggregate of merely commercial activities; it is also an ideological framing of history, nature and tradition; a framing that has the power to reshape culture and nature to its own needs’ (1999, p. xii). With deliberate hyperbole, the architects MVRDV speak of a Norway turned from a forest to a supervillage, the Alps becoming a park with hotel cities, France changing into a ‘‘Guid du Routard’’ landscape, in which the agricultural products became the instrument for a gastronomically oriented zone penetrated by hotels and restaurants according to special nostalgic rules and Tuscany as an ‘international villa park’, where ‘gigantic private gardens are maintained by the former farmers’ (MVRDV, 2000, p. 57). Meanwhile, other areas become associated with ‘ludic’ activities – spaces where play is not only allowed, but in many cases, demanded. Tourism there forms a ‘territorialized hedonism’ (Löfgren, 1999, p. 269). We might think of these as liminal zones with social rituals where normal rules of conduct are suspended, in times and spaces apart from the everyday (Shields, 1991).

Critical accounts point out that touristic meanings for places can clash with or replace local ones – thus eroding an original sense of place and reducing it to simulacrum or placelessness. This ‘erosion thesis’ that sees change as diminishing original cultures and reducing global differences (Hannerz, 1996) risks presupposing a ‘coercive conceptual schema’ of tourism ‘impacting’ on local cultures seen as pitted against a global industry and cultural changes arising from tourism resulting from ‘the intrusion of a superior sociocultural system in a supposedly weaker receiving milieu’ (Picard, 1996, pp. 104, 110). It also echoes a tendency in academic work to denigrate tourists almost as another species – which Löfgren parodies as ‘turistas vulgaris’ (1999, p. 264) – who travel in ‘herds’, ‘stampede’ on to beaches, ‘flock’ to see places and ‘swarm’ around ‘honey-pots’.

town A general name for an urban place but, like both a city and a village, with no generally accepted criteria on which to distinguish such a settlement. Such definitional problems constrain both historical analyses (e.g. urban origins) and planning for urban futures.

townscape The observable units of urban form that can be mapped and classified. Early work in urban geography focused on morphology – the patterns of land use and built form (such as street layouts and building heights), and the processes underpinning their evolution – with little reference to their visual appearance in the landscape. A rigorous approach was developed by M.R.G. Conzen (1907–2000: see Conzen, 1969), who identified three main townscape elements: the town plan (within which the other two were largely constrained), the land-use units and the built form. His pioneer work has been developed into studies of not only the patterns of urban morphology but also of the agents who shape and re-shape it, including pioneer studies by Whitehand, Larkham and others in the University of Birmingham’s Urban Morphology Research Group: the International Seminar on Urban Form launched the journal Urban Morphology in 1997.

trade Under normal capitalist conditions, the transportation and exchange of commodities for money. As such, trade provides a vital link between production and consumption in capitalist commodity chains. It is through trade that commodities reach their markets, and it is only when commodities are sold into markets that the value produced by the exploitation of workers is abstracted out and represented in the exchange values or prices generated by market trading (Harvey, 1999 [1982]). For these reasons, trade derives both its immense significance and considerable contemporary contentiousness from the ways in which it is interwoven with the wider political–economic organization of capitalism.

When it occurs across national borders, trade serves to create international economic ties. As a result, international trade statistics provide some of the best data available about the actual economic interdependencies underpinning globalization. Trade data showing...
global increases in international trade outstripping growth in overall global GDP provide a useful indication of the degree to which contemporary forms of capitalist development are characterized by increasingly cross-border flows (Dicken, 2003). Roughly 40 per cent of international trade is actually *intra-corporate trade* – that is, border-crossing trade that nevertheless remains within the internal commodity chains of a particular TNC (Gabel and Bruner, 2003) – revealing the corporate control of these flows within the networks of global corporations (see *transnational corporations* (TNCS)). Meanwhile, maps of import–export data (see figure) exhibit the uneven economic integration and triadic geographical structure of these economic flows, in which over 80 per cent of trade takes place between Europe, North America and Asia. Yet while trade data can help us better map global capitalism’s *uneven development*, the contentious debates over today’s *terms of trade* also need to be understood in relation to the profoundly politicized discourses surrounding the asymmetries and inequities of trade-mediated interdependencies.

Many free market fundamentalists insist that trade is always good without ever pausing to consider such basic questions as: The trade of what? For whom? And under what contextual conditions? The transatlantic slave trade
that turned Africans into commodities, for example, can hardly be held up as an unmitigated good (see Wolf, 1982). And the recent for-profit trade in blood plasma from Haiti to the USA and Europe reveals how despite historic victories over SLAVERY, its legacies still provide a vampiric verso of economists’ unending odes to free trade in the present (Farmer, 2006). But even putting such odious examples aside, studies of the political and economic geographies in which trade takes place make universal claims about the goodness of trade seem absurd (Sheppard and Barnes, 1990; Merrett, 1996; Porter and Sheppard, 1998; Gilbert, 2005). One of the major weaknesses of mainstream macroeconomics is that it continually abstracts from these geographies, mirroring but ignoring the ways in which capitalist trading relations affix prices to commodities that crystallize out their abstract value (but see Fireside and Miller, 2005). All the focus is on the economic benefits – never on the social, political and environmental ills that commodity production and trade so often entails.

Going back to David Ricardo’s nineteenth-century account of COMPARATIVE ADVANTAGE – which abstracted from the political–economic imperatives that were driving British manufacturers to seek new foreign markets for their products – abstractions such as ‘opportunity costs’ have continually led economists to obscure the uneven international and personal POWER relations in which trade takes place. Yet notwithstanding endless economic MODELLING demonstrating the supposed efficiencies of trade, and notwithstanding the repeated emphasis on the gains from trade in economics textbooks, the geographical context of trade still matters – and often reveals the losses from trade. This has become especially clear in contemporary debates over free trade and fair trade.

When the novelist Margaret Atwood joined other Canadians in contesting the Canada–USA Free Trade Agreement, she pointed to the discursive power of free trade by underlining how it hinges on the positive association of the word ‘free’, ‘as in free gift, free lunch, free world and free speech’ (Atwood, 1993, p. 93). Against this, Atwood argued that free trade in fact represented the systematic straitjacketing of Canada’s democratic autonomy and policy-setting freedom. Many other critics in Canada repeated the argument that free trade threatened everything from public health services to national development initiatives to food safety to cultural creativity. Subsequent protests from Seattle to Singapore have made similar arguments against the WORLD TRADE ORGANISATION, underlining the many areas of social, political and environmental policy-making that are straitjacketed by trade laws (Peet, 2003; Wallach and Woodall, 2004). At the heart of these criticisms is a concern with the ways in which free trade agreements create systems of rule or state effects that, while granting TNCs quasi-constitutional rights, simultaneously undermine any sort of democratic rights for the subject populations who want to question and reform the new rules (Gill, 2003; El Fisgón, 2004; Sparke, Brown, Corva et al., 2005). Based on these concerns and critiques, diverse transnational groupings from the WORLD SOCIAL FORUM to the Intercontinental Caravan are converging to deliberate and delineate diverse alternatives, including diverse forms of fair trade (Featherstone, 2003; Routledge, 2003; Sparke, Brown, Corva et al., 2005; Routledge, Nativel and Cumbers, 2006). Meanwhile, new work by feminist economic geographers points hopefully (and despite its capitalist government funding) towards non-capitalist, extra-capitalist and, most idealistically, post-capitalist forms of trade that is ‘free’ – from POVERTY, PATRIARCHY and corporate control (Gibson-Graham, 2003c: see also FEMINIST GEOGRAPHIES).
decades and is frequently invoked as a guide to renewable resource management (see Wade, 1987). Although he was not the first to draw attention to ‘the dilemma of collective resources’ (Gordon, 1954), Hardin ‘codified into a social economic theory’ the ‘conventional wisdom…that private gains might hold social and ecological costs’ (Robbins, 2004). Thus has the tragedy of the commons acquired the status of resource management parable, and has provided intellectual support to both calls for resource privatization and to demands for increased state control.

Since the first publication of Hardin’s argument, however, a substantial body of work by both natural and social scientists has documented the remarkable diversity of contemporary property management arrangements around the world (Berkes, 1989). This work demonstrates that successful collective management regimes cannot accurately be characterized as ‘exceptions’ or pre-modern relics: collective resource management regimes are widespread, are not restricted to developing countries, and can be resilient in the face of economic and environmental change. This work has shown that Hardin’s error was to move too quickly from an initial observation – about the significant tensions between private and collective interests – to his conclusion that collective management must fail. In practice, ‘the commons’ are not the open-access, free-for-all regimes that he made them out to be; rather, what distinguishes common property from open-access regimes are the customs, rule systems and enforcement mechanisms that condition individual access to and use of the resource. Furthermore, Hardin’s conclusion can only be sustained if one assumes that resource users cannot communicate with each other, share information on the condition of the resource, or coordinate their behaviour.

The past few years have seen renewed theoretical interest in the adaptive capacities, negotiated rule systems and indigenous environmental knowledges that often characterize common property management regimes. Given the failure of many ‘top-down’ development and conservation initiatives, these attributes are increasingly seen as valuable components of sustainable development and adaptive management in the face of environmental change.

**Transaction costs** The costs associated with effecting an economic transaction, either through market exchange between two or more legally distinct economic actors, or internally within a single organization (firm or, more generally, ‘hierarchy’).

Costs for market-mediated transactions might include:

- The cost of gathering information concerning the availability, price and quality of particular commodities (goods or services).
- The costs associated with identifying potential customers.
- The cost of determining the reliability of a supplier or the creditworthiness of a purchaser.
- The costs associated with negotiating the terms of an exchange, including price, delivery date and terms of payment (and of setting these out in the form of an agreed contract).
- The cost of completing a transaction (making or collecting payment).

Costs will also accompany non-market transactions within a single firm; in other words, the costs of organizing and coordinating complex, multi-step production processes in-house.

Transport costs associated with moving goods between transacting parties have traditionally received special attention from economic geography in general and have provided the basis for classical spatial models in location theory but, as the following discussion shows, other forms of transaction cost have recently attracted considerable attention within industrial geography in particular.

Williamson (1975, 1985) is generally credited with developing a comprehensive analysis of transaction costs. He sought ‘to achieve a better understanding of the origins and functions of various market structures – stretching from elementary work groups to complex modern corporations’ (1975, pp. 1–2). Instead of relying on technological arguments based on concepts such as indivisibilities or non-separabilities to explain why two or more functions might be performed within the same firm (‘organizational hierarchy’), Williamson focused on ‘transactions and the costs that attend completing transactions by one institutional mode rather than another’. He insisted that it was transactional not technological considerations that are ‘typically decisive in determining which mode of organization will obtain in what circumstances and why’. Most goods require a number of semi-finished or

**Suggested reading**

Feeny, Berkes, McCay and Acheson (1990); Ostrom (1999).
intermediate inputs for their production. They also require a number of discrete, separate functions to be performed as part of the overall production process. Williamson argued that the extent to which all of these operations are performed within a single vertically integrated firm versus the extent to which some or all of the required inputs are produced by other firms and then acquired through a market transaction depends on which mode of organization most successfully minimizes transaction costs: 'whether a set of transactions ought to be executed across markets or within a firm depends on the relatively efficiency of each mode' (p. 8). Generally, the more difficult or expensive the task of coordination or 'governance' of the production process, Williamson proposed, the greater the likelihood that production will be vertically integrated within a single internal hierarchy.

The geographical significance of transaction costs (other than transportation costs) was first made clear by Scott (1988c), who demonstrated both theoretically and empirically that the spatial clustering of firms often serves to reduce the cost of transactions between them (see cluster; industrial district). Under such conditions, firms will find it cheaper and easier to acquire the requisite information concerning potential suppliers and buyers nearby. Moreover, because such firms may be managed by individuals who have come into contact with one another repeatedly over extended periods of time, they may have built up a high degree of familiarity and trust between them that serves to facilitate the sharing of information and the successful achievement of non-routine transactions (Harrison, 1992; Nootebloom, 2006) – what Storper (1997b) called 'untraded interdependencies'. When such circumstances prevail, Scott argued, one should expect to find a much more fully articulated social division of labour, in which individual firms specialize in the production of a relatively small number of goods and/or services and trade actively with one another. Such arrangements are likely to be especially useful in industries for which market tastes are changing rapidly, and in which product life cycles are short. Since input requirements for such goods will also change rapidly, spatial concentration will reduce the transaction costs associated with producers finding and assessing the performance characteristics of potential new suppliers. Similarly, when the product is complex or highly customized, it is advantageous for producers and users to interact frequently and easily. Possibilities for achieving this are enhanced when the producer and user are close to one another, thereby reducing the cost of such a complex transaction (Lundvall, 1988).

Hence, as Storper (1997, pp. 34–5) observed, this kind of analysis demonstrates that geography figures in transaction costs in general, and hence influences the boundaries of the firm and production system. He also concluded that 'the geography of transaction costs helps explain agglomeration and spatial divisions of labour'. However, the transaction cost approach has been criticized for its rather reductionist analysis of industrial organization – for its 'exclusive focus on the transaction rather than the relationship' (Powell, 1990, p. 323) – and for its tendency to ignore the influence of the public sector in shaping the institutions (such as markets) that mediate exchange (Harrison, 1997). MG

**transactional analysis** In economic geography, a method of determining the number of firms in an industry and the nature of exchanges between them. It is based on the proposition that 'the economic institutions of capitalism have the main purpose and effect of economizing on transaction costs' (Williamson, 1985, p. 17). Thus it may be cheaper for a firm to produce a commodity 'in-house' through an internal transaction, in order to exploit internal economies of scope or to reap internal economies of scale, or it may be cheaper for a firm to acquire the same commodity through an external transaction (e.g. subcontracting), the cost of which may be reduced by the clustering of suppliers near to the firm (see cluster). This type of analysis illuminates one of the forces said to propel the agglomeration of productive activities. Transactional analysis is also an approach used in psychology and psychotherapy; advertised as explicitly post-Freudian, transactional analysis in this second sense places its focus on interpersonal interactions (cf. psychoanalytic theory). Approaches of this kind, so Bondi (1999) argued, suggest various affinities with some versions of humanistic geography.

**transculturation** The entwining and entangling of different cultural forms and practices to produce new ones (cf. hybridity). The term was originally proposed by Cuban ethnographer Fernando Ortiz (1881–1969), who contrasted transculturation to acculturation. Acculturation involves the adjustment of a subordinate culture to the impositions and exactions of a dominant culture, a process of
transfer pricing  The setting of transfer prices for products (goods and services) moving between semi-autonomous divisions (cost- or profit-centres) within large organizations. The practice is most often associated with TRANSNATIONAL CORPORATIONS (TNCs), which respond to variable corporate tax regimes, to TARIFF and other barriers to TRADE, and to differential exchange rates by setting prices for internal transactions between establishments located in different national jurisdictions in ways that minimize costs or maximize gains. For example, firms may charge high prices for semi-finished products shipped for further processing to plants located in jurisdictions with high rates of tax, so that they reduce the tax take on profits generated by finishing processes.

As the GLOBALIZATION of INVESTMENT, production and trade proceeds, both the possibilities for and the extent of transfer pricing are likely to increase. Dicken (2007, p. 239) points out that in general, the greater the differences in levels of corporate taxes, tariffs, duties, exchange rates, the greater will be the incentive for the TNC to manipulate its transfer prices’. TNCs have a strong incentive to engage in transfer pricing and the very large, highly centralized, global TNC has the greatest potential for doing so. The problem, as Dicken recognizes, is that it is exceptionally difficult for governments (or researchers) to obtain evidence about its extent.

Transfer prices are set by and within firms and, at one level, are purely managerial, involving the monitoring and control of individual cost- and profit-centres. But at another level, the judicious use of internal transfer pricing facilitates the avoidance of tax and minimizes the cost-of-trade barriers. Firms can optimize their financial relations with the jurisdictions in which they are located and so minimize payment of TARIFFS, for example, or shift accounted profits from locations within high-tax regimes to locations with low rates of corporate taxation. TNCs can also get around difficulties associated with fluctuating exchange rates which, on the open MARKET, might tend to over- or under-pricing of products in transactions taking place between units of the same TNC located in different currency spaces. By disembedding themselves in such

learning and even ‘acquiring’ the idioms of the dominant culture, whereas transculturation involves a dialectical relation of combination and contradiction (see DIALECTIC), a process of cultural loss as well as gain, that produces new, original forms (see also CULTURE).

Ortiz developed the concept in his masterwork, Cuban counterpoint (1940). As the title suggests, transculturation has something in common with studies of CONTRAPUNTAL GEOGRAPHIES: it is about the interplay between different cultures situated within a global force-field. The book was a study of the colonization of his native Cuba, where Ortiz identified a series of remarkably rapid cultural readjustments forcefully made by different peoples in a stream of migrants (Spanish, African and others), ‘each of them torn from [their] native moorings, faced with the problem of displacement and readjustment, of deculturation and acculturation – in a word, of transculturation’ (1995 [1940], p. 98). This may not have been a one-sided process of adjustment and compliance, but it was none the less a violent one: ‘All, those above and below, living together in the same atmosphere of terror and oppression, the oppressed in terror of reprisals, all beside justice, beside adjustment, beside themselves. And all in the painful process of transculturation’ (p. 102). The subtitle of Ortiz’s text is also critical: Ortiz’s analysis was a profoundly MATERIALIST one that focused on the significance of non-human actors (what ACTOR-NETWORK THEORY would call ‘actants’). He described tobacco and sugar as ‘the two most important figures in this history of Cuba’, and showed how different groups of people exercised power through their alliances with them. The cultural forms and practices of colonizers and colonized were thus reworked through their material, practical involvements with these two commodities. As anthropologist Fernando Coronil puts it in his introduction to Ortiz’s text, on this reading commodities are ‘not merely products of human activity, but active forces which constrain and empower it’ (see COMMODITY).

If Ortiz’s work is not understood in relation to Cuba and LATIN AMERICA more generally, it becomes a TRAVELLING THEORY that runs the risk of losing its political force (Lund, 2001). That said, transculturation has acquired considerable significance in POST-COLONIALISM and studies of TRAVEL-Writing, where it has allowed more subtle analyses of the considerable cultural traffic that constituted the ‘contact zone’ between colonizer and colonized (Pratt, 1992). But little of this work has seized upon the materialist dimensions of Ortiz’s work (cf. Coronil, 2000).
ways, TNCs are able to reduce their costs and increase their profitability at the expense of the jurisdictions in which they operate. RL.

Dicken (2007, ch. 8).

**transferability** One of Ullman’s (1956) bases for spatial interaction covering both transport costs, which reflect the characteristics of the transport system and the commodity being moved, and commodity’s ability to bear those costs. Precious metals have high transferability, for example, because they are easy to handle and transport costs are small (per unit weight) relative to their total value; plate glass has low transferability because it is difficult to handle and has relatively low value. RJ

**transgression** The act of crossing accepted limits, of breaking rules or exceeding boundaries. Transgression challenges but also reveals and underlines the values considered to be ‘normal’ and ‘appropriate’ in particular geographical and social settings. It works within and plays upon given spaces and conditions, rather than operating from outside them or seeking to constitute a new space or system. Through the process and the reactions to it, norms and codes about what is prohibited and considered proper are highlighted. For Bataille, whose writings have been particularly influential on understandings of the concept, the ‘experience of transgression is indissociable from the consciousness of the constraint or prohibition it violates; indeed, it is precisely by and through its transgression that the force of a prohibition becomes fully realized’ (see Suleiman, 1990, p. 75). Transgression and the taboo therefore coexist in a complex relationship, with the former not denying the latter but transcending and completing it (see also Foucault, 1977b [1963]; Jenks, 2003).

**Geography** is important in the constitution of limits and in demarcations of high and low, normal and deviant, clean and polluted and the like. While space is used as a means of social control by the powerful, the resulting socio-spatial orderings and codings may also be potentially transgressed. Despite many celebratory accounts of transgression, Stallybrass and White (1986) insist that there is nothing inherently politically progressive – or conservative – about the process. In their investigation of the construction of European bourgeois identity that ranges across social formations, space and the body, they examine the ways in which that identity was defined through the exclusion of what it deemed ‘low’, and how that expelled ‘other’ became a focus of desire as well as disgust. In their view, transgression is often ‘a powerful ritual or symbolic practice whereby the dominant squanders its symbolic capital so as to get in touch with the fields of desire which it denied itself as the price paid for its political power’ (1986, p. 210). The continual ‘rediscovery’ of the carnivalesque within modern culture and its importance as a semiotic realm is related to its rejection in the constitution of bourgeois culture’s self-identity.

Analysing transgression is therefore a significant means of understanding not only marginal acts, but also the processes by which the normal, the central and the dominant become defined. Transgression’s power comes in particular from its ability to expose the constructedness of socio-spatial orderings, and hence their openness to criticism and to reconstruction. Transgression is distinct from resistance, according to Cresswell (1996), in that it does not rest on intentionality, but on its effects and on the reactions it precipitates. These cannot be defined in advance, but have to be examined in particular geographical and historical contexts. ’Transgression’s efficacy lies in the power of the established boundaries and spaces that is so heretically subverts,’ he states. ’It is also limited by this established geography; it is always in reaction to topographies of power’ (Cresswell, 1996, p. 175). Yet, as he remarks, transgression can contain ‘the seeds of new spatial orderings’. It may, through becoming part of strategic struggles, go beyond temporary tactical incursions to contribute to social and spatial transformation.

Cresswell (1996); Stallybrass and White (1986).

**Transhumance** Socially organized seasonal movements of livestock along altitudinal and bioclimatic gradients, usually in response to changing availability of forage or water. These movements differ from those associated with nomadic pastoralism (see Nomadism) in that only a portion of the family (or other social unit) associated with the herd makes the journey, while the remainder of the family remains at a more permanent dwelling. The term was originally used in Europe (the French verb transhumers means to move livestock) to describe the movement of shepherds...
and their flocks between lowland pastures in the winter and highland pastures in the summer months, to take advantage of snow melt. Such movements are historically tied to pastoralism in mountainous areas and dryland regions with seasonal rainfall.

**transnational corporations (TNCs)**

Capital moves around the globe in three forms: embodied in materials, goods and services, it enters into trade flows. Invested in stocks, bonds, foreign currency holdings and the like, it moves as financial capital (see finance; hot money). Transnational corporations (TNCs) invest their own capital resources in other countries in order to engage in their ordinary business of extracting, producing and/or selling materials, goods and services. This is also known as foreign direct investment (FDI). FDI may involve the creation of an operation from the ground up—a ‘greenfield investment’. More commonly, it involves buying an already existing foreign company. In either case, effective control over the offshore operation remains with the parent company, even if it does not own 100 per cent of the foreign asset. Return on investment may be in the form of royalties, interest or profits and these may be reinvested in the offshore site, repatriated to the parent corporation or invested elsewhere altogether.

FDI grows out of the combined exigencies of international competition and the push of capital accumulation as a company amasses more capital than it can conveniently or profitably reinvest in its original market. This implies a longer term commitment of resources to a particular foreign site than either of the other forms of international capital mobility, and corporations undertake it for a number of reasons. Control over natural resources is a classic motivation and the one most likely to draw a company into remote parts of the world. Tapping into low-cost and non-unionized labour markets is another. FDI may be a way of internalizing transaction costs across borders and taking advantage of economies of scope, greater capital resources or technologies in order to gain a competitive advantage in foreign markets. A TNC may buy out a foreign company in order to gain access to proprietary technology or to reduce the intensity of competition in its business. Or it may be intent on gaining access to or improving its position in important foreign markets and sees operating in the market as a better means to this end than exporting from home. This may be: because it can provide better service or respond more quickly to shifts in the market; because it will benefit politically from being perceived as a local company; because it avoids tariff barriers and transport costs, or because it can keep a closer eye on the competition (Schoenberger, 1997; Dunning, 2002a; Dicken, 2003; Ietto-Gillies, 2005).

The geography of TNC investment may be counter-intuitive. Conventional economic theory supposes that capital will flow from places where it is abundant and the price correspondingly low to places where it is scarce and therefore expensive. This implies a flow from advanced industrial countries to less developed countries across the board. Other theories anticipate that capital will flow from high-cost areas to low-cost areas, again implying an outflow from advanced countries, with high labour and regulatory costs, to the Third World (see new international division of labour) (Dunning, 2002b; Dicken, 2003).

Most non-resource FDI, however, flows among advanced industrial countries. US TNCs in manufacturing and services, for example, invest mostly in western Europe and Canada. European TNCs invest heavily elsewhere in Europe and in North America. A smaller share flows to just a handful of newly industrializing countries (NICs). Even TNCs from some NICs are investing now in North America and Europe: in 2005, a Chinese corporation, Lenovo, bought the personal computer business of IBM. Market access seems to matter more than costs. Further, since FDI is so often made via acquisition rather than as greenfield investment, it is likely to go where the largest number of potential acquisitions is located—advanced industrial countries (Schoenberger, 1997; Dicken, 2003).

Despite this skewed distribution in favour of advanced industrial countries, TNCs operating in developing regions still have a tremendous impact—in part because they may be quite large relative to the local economy. This is especially true of resource extraction operations, although even these are concentrated geographically in a relatively small number of host countries (Bridge, 2004).

Why FDI does not flow more generally across the surface of the Earth is an interesting problem. Its orientation to rich (North America and the EU) and/or fast-growing (e.g. Asia) markets is an important factor. Economies of scale in many of the most important FDI industries (e.g. mining or
TRANSACTIONALISM

Chemicals) favour geographical concentration. Progress in automation has reduced the importance of labour costs in many sectors, making it feasible to remain in high labour cost countries. Meanwhile, poorer countries, besides having very restricted markets, also have poor physical and institutional infrastructures, which makes operations both more costly and riskier. Although usually seen to be in the vanguard of GLOBALIZATION, there are reasons to suppose that TNCs are hedging their bets. Their operations are certainly international, but they are not quite global as yet.

TNCs are the permanent object of heated political debate. Some believe that they will foster ECONOMIC GROWTH and MODERNIZATION in the developing world by importing capital, technology and managerial techniques that will then filter out into the host economy. STAGES OF GROWTH theorists see TNCs as the perfect vehicle for overcoming barriers to DEVELOPMENT and promoting REGIONAL CONVERGENCE. Others believe they are responsible for ‘underdeveloping’ the Third World by dominating local markets and draining capital in the form of profits from SOUTH to North – in short, that they are the modern form of IMPERIALISM and a major factor promoting DEPENDENCY and UNEVEN DEVELOPMENT. Many see them as responsible for the DEINDUSTRIALIZATION of formerly prosperous regions (Tabb, 2002; Cuyvers and DeBeule, 2005). TNCs have been charged with collaborating with oppressive governments in order to ensure access to resources and therefore being implicated in the violation of human rights and of violence against local populations (Peluso and Watts, 2001; Frynas and Pegg, 2003). Their presence raises questions of sovereignty and the integrity of the NATION-STATE even in the most developed countries (Dicken, 2003).

Suggested reading

transnationalism A concept that describes a movement or set of linkages that occur across national BOUNDARIES. Transnationalism is a relatively new term, and its growing popularity indicates the heightened interconnectivity of people and things that now flow across borders and BOUNDARIES in greater volume and with greater speed than ever before. While closely linked to the processes of economic GLOBALIZATION, which are often conceptualized in abstract global terms and decentred spaces, transnationalism is generally invoked to express transcendence of the specific workings of the NATION-STATE (Kearney, 1995). It is thus used most widely in the social sciences to describe phenomena in which the cultural or territorial boundaries of the NATION and/or the regulatory apparatuses of the STATE are crossed or contested in new kinds of ways.

While this notion of crossing boundaries is pertinent to many cross-border articulations, including the circulation of Commodities and the flows of culture and ideas (e.g. Jackson, Crang and Dwyer, 2004), the contemporary movement of migrants is most frequently associated with the term. Unlike earlier theories of MIGRATION, which generally characterized movement across borders as either permanent rupture followed by assimilation in a new society, or as temporary sojourning followed by a return home, transnationalism describes a migration pattern of simultaneous connection to two or more nations (Basch, Glick Schiller and Blanc, 1995). In numerous case studies, migrants have been shown to construct an intricate, multi-webbed NETWORK of ongoing social relations that span their country of origin and their country (or countries) of settlement. While a pattern of transnational life has been present in past migrations to varying degrees, the new transportation, communication and computing technologies of the past few decades have greatly facilitated such arrangements in the contemporary era.

In addition to technological advances, many scholars have associated the growth of this type of migration pattern with changes in the nature of global CAPITALISM (Ong, 1999). The organization of production on a worldwide scale has affected the volume and flow of migrants across national borders, and led to a transformed culture and experience of migration and of the nation. These dynamics are implicated in the wider boundary-crossing conceptualization of transnationalism, in which the significance of national cultural narratives and the meanings and practices of state regulations are reconsidered and often reworked. One of the key signifiers of both cultural belonging and state control that is reworked under conditions of contemporary transnationality is CITIZENSHIP. The implications of transnationalism for citizenship formation are enormous, ranging from questions of state jurisdiction over borders to sociocultural considerations of IDENTITY and belonging.

K M
transport costs  The total costs involved in moving between two places, which in the case of goods movements involves not only the freight rate but also the costs of documentation, packaging, insurance and inventory. Transport costs are a central element in most classical location theories, being presented as a primary determinant of both agricultural land use (see von Thünen model) and industrial location theories, as well as most theories of spatial interaction (cf. distance decay): they were at the heart of arguments for geography as spatial science, or as a 'discipline in distance' (Watson, 1955; cf. locational analysis). RJ

transport geography  This field of study focuses on the movement of people and goods, the transportation systems designed to facilitate such movement, and the relationship of transportation to other facets of human geography such as economic development, energy, land use, sprawl, environmental degradation, values and culture. Long-standing, strong ties with the fields of civil engineering and economics have imbued transport geography with a tradition of quantitative methods, particularly the use of mathematical models. These ties have at once enabled transport analysts to respond to pressing planning problems and tended to limit the questions that transport geographers ask, often directing attention towards technique and away from theory (Hanson, 2000).

Studies of the movement of people and goods have sought to build predictive models of the volume of flows between places; these models predict flows as a function of the demand for movement between nodes (usually associated with various measures of node size) and the cost of movement between nodes, which in turn is related to distance, the mode of travel (e.g. airplane, ship, automobile), and the ease of movement, inter alia. Such models of spatial interaction are important to a range of actors including urban transportation planners, who are responsible for providing transport facilities that will handle predicted flow volumes, and commercial airlines, which must also provide sufficient capacity to meet predicted demand. In transportation geography, the linkages among modelling, prediction and planning have been exceedingly strong.

Studies of transportation systems have focused on patterns of networks and nodes and have often considered how these patterns affect ease of movement and therefore shape land-use and settlement patterns. In the USA, the advent of the inter-state highway system, beginning in the 1950s, led to the demise of some places by-passed by the system and to the growth of other places, whose accessibility was enhanced by connection to the inter-state system (Garrison, Berry, Marble, Nystuen and Morrill, 1959). More recently, the deregulation of the airlines led to the development of the hub-and-spoke system that describes the current network of air travel in the USA (O’Kelly, 1998); again, the network configuration favours certain nodes (the hubs, many of which have grown into thriving commercial centres) to the detriment of others (nodes at the extremities of the spokes, which have seen their accessibility via air decline). Transport systems studies have also examined competition between and among modes (e.g. trucking versus the railroads and waterways) and between and among routes on the same mode (e.g. among the multiple routes between Chicago and the US east coast in the early twentieth century). Of current interest is the impact of Internet commerce on transport: whereas such commerce might reduce the number of person-trips, it has led to an enormous increase in the demand for goods movement (Aoyama, Ratick and Schwarz, 2006).

Transport is intimately related to a host of issues that lie at the heart of human geography. Energy consumption and environmental degradation are just two that link closely to the nature-society tradition in geography. Because transportation systems are designed to increase accessibility and accessibility is central to land-use patterns and to economic development, transport studies have much to offer the field of development. Values and culture, which are hugely important to understandings of transport patterns and systems, have been mostly neglected by transport geographers. SfHa

travel writing A genre of prose about the experience of being away from home. While travel writing in EUROPE can be traced back to Homer’s Odyssey, it has rarely been considered either serious LITERATURE or credible ETHNOGRAPHY, and was typically excluded from the conventional history of geography (see GEOGRAPHY, HISTORY OF). In the past several decades, however, the genre has been reassessed within the HUMANITIES and the social sciences, and there has been a resurgence of critical interest in travel writing. This can be traced to a number of broader changes in academic fashion. One was the rise of POSTMODERNISM, which validated the study of popular forms of CULTURE, including writing, rather than simply ‘the Greats’. Within many of the social sciences, postmodernism was closely associated with a CULTURAL TURN that focused greater attention on practices of REPRESENTATION. A second, related source of interest in travel writing was the development of POST-COLONIALISM and the key role played by literary scholar Edward Said (1935–2003) in its articulation. The success of Said’s (2003 [1978]) critique of ORIENTALISM created a multidisciplinary growth industry in the study of colonial representations of other places and peoples. Travel writings were seen as primary sources for the recovery of IMAGINATIVE GEOGRAPHIES. A third influence was FEMINISM, which showed that nineteenth- and early-twentieth-century travel accounts written by women were important but marginalized sites of the production of geographical knowledge (indeed, they had been marginalized by Said too) (cf. McEwan, 2000).

Within HUMAN GEOGRAPHY, interest in travel writing has had a number of different foci. Among these has been a renewed interest in records and writings produced under the signs of EXPLORATION and SCIENCE, but now read critically as TEXTS, using the resources of the literary as well as the historical disciplines to disclose the multiple ways in which the DISCOURSE of exploration and enumeration worked to produce its objects of inquiry. As the discourse of Orientalism produced ‘the Orient’, for example, so the discourse of TROPICALITY produced ‘the Tropics’ (Driver and Martins, 2005). Such studies feed into an interest in the spaces through which scientific knowledges are produced, the channels through which they circulate and the centres at which they accumulate. The same spatial thematics animate studies of travel writing outside the nominally scientific domain (Gregory, 2001a). In Europe, the distinction between ‘travel’ and ‘TOURISM’ is an historical one, freighted with assumptions about edification and independence that register a series of CLASS distinctions. But travellers and tourists throughout the nineteenth and on into the twentieth centuries had a compulsion to WRITE their journeys, and the critical scrutiny of their texts has much to tell us about not only the production, and on occasion the disruption, of cultural stereotypes and processes of TRANSCULTURATION (Pratt, 1992) – few travellers arrived at their destination with their cultural baggage intact and simply unpacked it to make pre-configured sense of what they saw – but also about the formation of national IDENTITIES and the consolidation of bourgeois CULTURE (Buzard, 1993; Duncan and Gregory, 1999). Travellers did not only write diaries, journals and letters; they also sketched, painted, and took photographs, and the interrogation of this visual archive has been of considerable importance in the recovery and analysis of cultural constructions of LANDSCAPE in particular (Stafford, 1984; Osborne, 2000; Schwartz and Ryan, 2003). Travel was also historically coded through notations of GENDER and SEXUALITY, and there has been a notable interest in the ways in which travel could permit the realization of DESIRE and TRANSGRESSION that was simply impossible at home (Aldrich, 1993; Boone, 1995; Gregory, 1995a).

This brief summary suggests a series of lacunae in work on travel writing that are only now starting to be addressed. First, research has been dominated by studies of European and North American travellers beyond their own shores – but what of the ‘return gaze’ (e.g. Burton, 1998)? Second, the texts under closest scrutiny were typically produced by those who CHOSE to travel under the signs of science, culture or pleasure – but what of the experiences of those who were obliged to travel under other signs: commerce, capture or duty (e.g. Colley, 2002), or as fugitives from disaster or WAR (see REFUGEES)? Third, much of this work has fastened on historical rather than contemporary writings, a focus...
that forecloses questions about the complex reactivation of older, often colonial images in our own present (cf. Tavares and Brosseau, 2006) and the ways in which what Lisle (2006) calls ‘the global politics of contemporary travel writing’ now participates in and responds to the anxieties created by globalization.

travelling theory Intellectual ideas that move from one location to another and, in the process, change in response to new circumstances. The original formulation was by Edward Said, who identified three critical moments:

- The first was origination, the circumstances within which a body of ideas emerges. Ideas are not free-floating constructions, on this reading, and their analysis requires what historians of science and of geography call a ‘contextual history’. Said (1984, pp. 241–2) called for a ‘critical consciousness’, a ‘spatial sense, a sort of measuring faculty for locating or situating theory’ by understanding it ‘in the place and time out of which it emerges as part of that time, working in and for it, responding to it’ (cf. situated knowledge).

- The second was institutionalization. Said knew very well that ideas move – the circulation of ideas is an enabling condition of intellectual activity – but he was also concerned that as radical, unsettling ideas become fashionable so they are domesticated: ‘Once an idea gains currency because it is clearly effective and powerful, there is every likelihood that during its peregrinations it will be reduced, codified and institutionalized’ (Said, 1984, p. 239).

- The third was revivification. Said subsequently accepted that a theory could be reinterpreted and reinvigorated by travelling and responding to a new situation. These transgressive theorizations – his examples were Adorno and Fanon – give one a sense of ‘the geographical dispersion of which the theoretical motor is capable’ by pulling ideas from one region to another and realizing the productive possibility of ‘actively different locales, sites, situations for theory’ – a sense of active, operative, concrete differences – that allow no ‘facile

universalism or over-general totalizing’ (Said, 2000 [1994], p. 452).

Said’s own account of ORIENTALISM has been interpreted as a classic instance of travelling theory (Brennan, 2000).

In HUMAN GEOGRAPHY travelling theory has its place in a wider landscape that includes geographies of intellectual production, dissemination and circulation, and reception. Journeying across this landscape raises important and interrelated questions about the fixation of high theory on fashionable thinkers; about the COMMODITY CHAINS that make up the international publishing industry; about the trafficking in metropolitan ‘high theory’ and the use of other regions as resource banks; about the dominance of English-language publication and the problems of translation (see ANGLOCENTRISM); and about the place of the modern corporate university and its relation to other sites at which geographical knowledge is produced (cf. PUBLIC GEOGRAPHIES).

It is not only ideas that travel, and Livingstone (2003b) sees travelling theory as part of a larger apparatus of circulation that is indispensable to the scientific enterprise: ‘Ideas and instruments, texts and theories, individuals and inventions – to name but a very few – all diffuse across the surface of the earth (see SCIENCE).’ Their circulation raises similar questions about the hierarchies and the NETWORKS through which they move, both inwards and outwards, and their reception and reworking also raises questions about IDEOLOGIES of respect and techniques of TRUST: ‘Scientific knowledge has been expanded by circulation . . . [but] distance and doubt have always been close companions’ (p. 178). DG

trend surface analysis A technique developed by Chorley and Haggett (1965) for generalizing the pattern in a set of geographical data. It usually employs a form of multiple REGRESSION in which the independent variables are the grid coordinates for the observations and the dependent variable is some item of interest measured there – such as land elevation. The aim is to identify the salient features of a complex three-dimensional SURFACE.

trialectics A term proposed by the American geographer Edward Soja (1996b) as ‘a mode of dialectical reasoning that is
more inherently spatial than the conventionally temporally-defined dialectics of Marx or Hegel’ (p. 10). In contrast to dialectics, Soja identified three moments (not two), each of which is supposed to contain the others. Soja’s purpose was to insist on the importance of the ‘third term’ in order ‘to defend against any binary reductionism or totalization’. This is more than an exercise in logic, although Soja develops his argument at a high level of abstraction. He proposes two basic trialetics (see figure).

The first trialectic is primarily concerned with ontology: Soja (1996b, pp. 71–3) describes this as the trialetics of being, and uses it to diagram the production of time, being-in-the-world and space: his argument turns on the claim that runs throughout his later writings that the ‘third term’, space, is characteristically erased in conventional social theory (cf. Soja, 1989).

The second trialectic is primarily concerned with epistemology: Soja (1996b, pp. 73–82) describes this as the trialetics of spatiality, and uses it to diagram three approaches to spatiality. These are derived from his reading of Henri Lefebvre’s account of the production of space. Following Lefebvre, then, Soja argues that most discourses of spatiality have been confined to the realms of either:

1. spatial practices, a space of objectivity and object-ness, of ‘perceived space’, that Soja calls Firstspace;
2. representations of space, a space of signification and subject-ness, of ‘conceived space’, that Soja calls Secondspace.

Here too it is the force of the ‘third term’ that Soja seeks to release:

3. spaces of representation, where representation carries both political and cultural connotations, and whose animation as ‘lived space’ corresponds to the subversive, radical and even revolutionary potential of what Soja identifies as Thirdspace (see third space).

Soja (1996b, pp. 53–82); Merrifield (1996).

tricontinentalism An alternative term to post-colonialism that emphasizes the transnational locations and the political implications of critiques of colonialism and imperialism. The substitution was proposed by British literary/critical theorist Robert Young, who invoked the Tricontinental Conference, the meeting of the Organization of Solidarity of the Peoples of Africa, Asia and Latin America’, in Havana, Cuba in 1966 as, in effect, ‘the founding moment of postcolonial theory’ (Young, 2001, p. 5). Most accounts of post-colonial theory focus on three canonical figures – Edward Said, Homi Bhabha and Gayatri Chakravorty Spivak – rather than three continents. Young acknowledges the importance of these academic writings, but the purpose of Young’s redirection was twofold. First, he wanted to transcend the eurocentrism of much of what passes for ‘theory’ by drawing attention to the vital importance of those ‘insurgent knowledges that come from the subaltern, the dispossessed, and [which]
seek to change the terms and values under which we all live’: critical formulations that were rooted in the particular circumstances of exploitation and dispossession in AFRICA, ASIA and LATIN AMERICA (Young, 2003b, p. 20; cf. SUBALTERN STUDIES). Second, Young wanted to emphasize the political affinities between these knowledges and projects of popular liberation and DECOLONIZATION. In doing so, he acknowledged that Marx’s writings were often a crucial inspiration, but he insisted that this was an HISTORICAL MATERIALISM that did not survive the journey from EUROPE intact: it was reworked in creative ways that were directly tied to practical, political conjunctures elsewhere in the world (see TRAVELLING THEORY).

Bongie (2002).

tropicality Cartographically, the Tropics are defined by the latitudinal lines of Cancer and Capricorn around the GLOBE, 23 degrees and 27 minutes north and south of the Equator, within which the sun may shine directly overhead. However, in cultural and political terms, tropicality – like ORIENTALISM – is not a fixed or a given fact of geography: it is a way of thinking in which spaces are described METAPHORICALLY, associating ‘the Tropics’ with a certain kind of experience, vision, LANDSCAPE or SOCIETY (Arnold, 1996a; Driver and Martins, 2005). The conceptual mapping of the ‘tropical’ – as defined against the ‘temperate’ – is one of the most enduring themes in the IMAGINATIVE GEOGRAPHIES of the globe, from classical mythology to modern LITERATURE (Cosgrove, 2001). Whether represented positively as a zone of luxuriant superabundance (as in Alexander von Humboldt’s writings on tropical landscape), or negatively as a pathological space of degeneration (as in Joseph Conrad’s novel, Heart of darkness), tropical NATURE has frequently been employed as a counterpoint to all that is modest, civilized or cultivated – or, in a word, ‘normal’ (cf. Gregory, 2001b). Images of tropicality have thus had a sustained impact within DISCOURSES of EXPLORATION, travel and TOURISM, and are also to be found in a wide variety of other cultural forms, from landscape painting and epic poetry to architecture and popular MUSIC. In the history of SCIENCE, they are reflected in the emergence of distinct sub-disciplinary specialisms – for example, tropical medicine, tropical climatology (see CLIMATE) or tropical geomorphology – although the distinctiveness of the ‘tropical’ in these fields has always been contested. In the modern world, images of tropical difference have played a significant part in military imaginaries during WARS in ASIA and South East Asia in particular, and they continue to shape the ICONOGRAPHY of luxury tourism, global ENVIRONMENTALISM and commodity advertising more generally.

Although critical reflection on notions of tropicality is of relatively recent date (Arnold, 1996a; Driver and Yeoh, 2000), writings on the geographical characteristics of the tropical world have a long history. As the discipline of GEOGRAPHY developed in its modern form, the field of ‘tropical geography’ flourished for a brief period, notably in France during the mid-twentieth century, where the work of the geomorphologist Pierre Gourou (1900–99) – author of Les pays tropicaux (1947) – was particularly influential. Subsequent critiques of this work drew attention to its ideological blind-spots in relation to COLONIALISM and DEVELOPMENT, and its tendency to treat the impact of environment on society in a-historical terms. The history of tropical geography needs to be seen in the context of the colonial histories of the Francophone world, notably in Indochina. Recent work, however, casts new light on the ambivalent sense of tropicality within this tradition and the extent to which it supported the programmes of colonialism (Bowd and Clayton, 2005a,b). More generally, the extent to which the idea of tropicality can be understood, like Orientalism, as a form of discursive projection imposed by the West remains a matter for debate. Notions of tropicality, whether geographical, scientific or aesthetic, are not simply the product of imperial fantasy: they also contain other experiences, and other possibilities (see also Arnold, 2006).

trust A quality that gives statements, individuals or organizations credibility and authority. Trust has become an important theme in areas of HUMAN GEOGRAPHY concerned to understand processes of knowledge credibility and transfer. ECONOMIC GEOGRAPHERS have addressed the ways in which economic relationships may depend upon trust between those engaged in transactions, with consequences for the value placed upon face-to-face contact, and the ways in which places may construct their economic reputation around trustworthiness. Thus Hudson’s (1998) study of the
offshore financial centres of Bermuda and the Cayman Islands emphasizes how the stabilization of such centres relies upon their capacity to be trusted as regulatory landscapes. Trust is here defined as ‘relatively stable expectations about the actions of others, a particular level of the subjective probability with which an actor assesses whether one or more actors, with whom cooperation is envisaged, will also cooperate’ (Hudson, 1998, p. 918).

Parallel concerns have shaped studies of the geographies of scientific knowledge, where the capacity for knowledge to be credible is connected to the capacity of scientists, including geographers, to be trusted. Livingstone discusses the ‘techniques of trust’ that developed in connection with geographical travel (2003c, pp. 147–71). Historical geographies of science in general, and of geographical science in particular, have connected trust to issue of class and gender, following Shapin’s studies of science in seventeenth-century England (Shapin, 1994), where a particular sense of gentlemanly civility was shown to be central to the emergence of scientific culture. Subsequently, Shapin (1998) directly addressed the spatiality of the trust relationship in the production and validation of science, including the finding of ‘means to bring distant things near’, and the ways in which ‘those who have not seen these things know them by trusting those who have, or by trusting those who have trusted those who have’ (Shapin, 1998, p. 8). Driver’s studies of cultures of exploration and empire have shown how the trustworthiness and credibility of geographical knowledge claims concerning distant regions were shaped through institutions such as the Royal Geographical Society, whether in their production of published ‘Hints for Travellers’, or their reception of the knowledge ‘brought back’ from Africa by figures such as Henry Morton Stanley. In the latter case, lack of trust in exploratory findings was bound up with judgements concerning the character of the explorer, with issues of ‘social standing, scientific merit and moral legitimacy’ becoming intertwined (Driver, 2001a, p. 129). The geographies of trust also encompass the questions of why geographers should be trusted, why the discipline should have credibility and who counts as a trustworthy geographer.

turf politics Political activity undertaken by residents of a neighbourhood to resist proposed changes that are viewed as potentially significant negative impacts upon the local community and also to promote changes that are perceived to carry potential positive impacts. The activity is usually locally based but is often oriented to the broader scales of local or state government (Ackerman, 1999). Catalysing changes usually take the form of development proposals (such as a new road), demographic change (such as the influx of a new ethnic group or social class) or investment decisions (such as continued funding for health facilities).

uncertainty The possibility of more than one outcome resulting from a particular course of action, the form of each possible outcome being known but the chance or probability of one particular outcome being unknown. Uncertainty differs from risk, in that under conditions of risk it is possible to know the probability of a particular outcome. For example, in tossing a coin the probability of heads coming up is 0.5, so betting on the toss of a coin is a risk. Playing Russian roulette is a risk (also ‘risky’) if the pistol is known to be loaded; with a bullet in one of the six chambers, there is a one-in-six probability of death with any shot. However, if it was not known whether the gun was loaded, this would be a situation of uncertainty.

Uncertainty is part of the environment within which locational decision-making is made. This greatly limits the practical value of theories and models that assume perfect knowledge. For example, the firm setting up a new factory or service outlet in a new territory cannot know what the reaction of competitors is likely to be. They may follow suit with new facilities of their own, they may find an alternative competitive strategy, or they may choose not to compete: there is no way of calculating the probability of each option. Residential choice is similarly made under conditions of uncertainty – for example, with respect to the stability of the neighbourhood or the sociability of the neighbours.

underclass This term was introduced in the USA to refer to multiply deprived individuals who experience a form of poverty from which there is virtually no escape (cf. cycle of poverty). In the USA, those classified as part of the underclass are mainly African-Americans or Latinas/os. Most lack higher education, skills that are in demand, and any apparent means of achieving upward social mobility. Many are from single-parent families and are living on social assistance. There is also a geographical dimension to the underclass: it is usually identified with stigmatized neighbourhoods that are areas of concentrated poverty and few job opportunities (Bauder, 2002). Members of the underclass experience a spatial mismatch in that they cannot find work where they live, but also cannot afford the cost of transportation (and childcare expenses) to obtain work in more distant areas of the city (Mingione, 1996). These problems are compounded by discrimination against women and minorities in labour markets (see gender). In recent years, the term has been used to apply to extremely poor populations outside the USA, in Europe and increasingly in the developing world (see, e.g., Breman and Agarwal, 2002; Keyder, 2005; Solinger, 2006: see also development).

While liberal and radical analysts emphasize the structural causes of poverty (the nature of capitalism, patriarchy and racism – Wilson, 1987; Gans, 1995), conservative authors concentrate on the personal characteristics and lifestyles of the disadvantaged (Auletta, 1982). This latter view usually draws upon the culture of poverty thesis outlined by Oscar Lewis (1959) in his anthropological studies of Latin American slums during the 1950s and 1960s. Lewis argued that the very poor share behavioural patterns that on the one hand allow them to cope with poverty, but on the other hand reproduce their disadvantage (e.g. a sceptical attitude towards education, that is passed on to children). While this was unintended by Lewis, his idea of adaptation to poverty has been taken up by conservative commentators who believe that people are poor because of choices they make. This ‘blame the victim’ mentality permeates through much of the underclass debate, at least in the USA. Because of the frequent association of the term ‘underclass’ with this conservative view, many critical scholars refuse to use it.

The size of the underclass appears to be growing in North America and Europe, as governments reduce the scope and universality of social programmes, and as mental health patients are deinstitutionalized. The impact of immigration on the underclass is also a topic of concern, and some authors believe that a new ‘rainbow underclass’ is forming in the USA (e.g. Portes, 2003; for an opposing view, see Waldinger and Feliciano, 2004). Public policy in Western countries tends to oscillate between liberal/radical and conservative views on poverty and the underclass,
sometimes targeting structural problems (e.g. the ‘war on poverty’ of the 1970s in the USA; the creation of the Social Exclusion Unit in 1997 in the UK; see SOCIAL EXCLUSION), while at other times attempting to change the behaviour of the poor by reducing welfare payments (‘welfare reform’ of the 1990s in the USA) and/or providing additional funds to those who are entrepreneurially inclined (Midgley, 2001; Peck, 2001b).

**underdevelopment** A term used to signify a comparative absence of development, but which is now less commonly used by scholars (though it retains its popular, even populist force). It emerged as part of a postwar discourse on economic growth in the third world, where it functioned mainly as an adjectival noun. Underdevelopment here functioned mainly as a noun. Modernization theorists grouped together a number of countries that they described as traditional or pre-modern. These countries had not yet ‘taken-off’ towards an era of high mass consumption (see stages of growth). By the standards of the USA and other ‘developed’ countries, they suffered from underdevelopment (Hoselitz, 1952). Underdevelopment here defined a linked set of states that included: being mainly agricultural or rural; being religious or even fatalistic in outlook, but definitely not scientific; being poorly served by roads, railways, schools and clinics; and being beset by high rates of population growth and poor environmental conditions. The Promethean ideology of development was meant to change all this, including in underdeveloped socialist countries. Aid and planning would be the handmaidens of the transition from a state of underdevelopment to a state of development.

We now see that many of the concerns expressed by modernization theorists in the 1950s and 1960s reflected the anxieties felt by US liberals (e.g. W.W. Rostow) and conservatives (e.g. Samuel Huntington) about economic and political development in post-war America. There was particular concern about the strength of authority relations at a time of rapid social change. These concerns were allied to an extraordinary faith in the view that all countries would one day learn to be modern in the American way. Both Rostow (directly) and Huntington (indirectly) were active in promoting the USA’s war in Vietnam in line with this secular faith. Communism was a deviant ideology that had to be defeated. Peasants had to be pushed (or bombed) out of the countryside, where they were coming under the influence of the Vietcong (Gilman, 2003). Significantly, however, a sparky group of Latin American scholars in the 1960s strongly challenged the idea that underdevelopment should be defined as an adjectival noun. Andre Gunder Frank (1966) famously declared that while all countries had at some stage been undeveloped, only in the ‘Third World’ had some countries been made underdeveloped. Frank, in other words, moved to redefine underdevelopment as an active verb. In his view it described not an original state of virgin forests and wilderness (see nature), but a grim landscape of impoverishment that had been created as part of the development of the capitalist world system. Capitalism, Frank suggested, created development and underdevelopment as two sides of the coin (see dependency theory). Arranging countries on a straight line from underdeveloped to developed made no sense. It ignored the active creation of their very different geographies by common processes of unequal exchange and uneven development.

Gilman (2003).

**uneven development** The spatially and temporally uneven processes and outcomes (socio-economic and physical) that are characteristic of, and functional to, capitalism. One of the most striking features of human geographies, particularly those activities and indicators conventionally labelled as ‘economic’, is their unevenness at every scale. This is evident in the organization of the global economy (e.g. the categories of First and Third Worlds, or core, peripheral and semi-peripheral countries); at regional scales within most countries (e.g. heavily industrialized or finance-centred regions versus ‘laggard’ or persistently poor rural areas); within metropolitan areas (e.g. ‘inner cities’ versus suburbs); and within many cities at neighbourhood and block-by-block scales.

**neo-classical economics** typically regards such unevenness as temporary, and assumes or predicts that capitalist development (‘economic growth’) will produce movement towards equilibrium over space and time, leading to eventual convergence (cf. modernization).
By contrast, marxist geography views such unevenness as actually produced by capitalism. Neil Smith, the leading geographical theorist of uneven development, emphasizes that it is not merely a reflection of a highly heterogeneous world in which perfect uniformity is always unlikely; nor is it even solely the result of the fact that it is useful to capitalists. Rather, it is an unavoidable consequence of capitalist as a mode of production, ‘... the systematic geographical expression of the contradictions inherent in the very constitution and structure of capital’ (Smith, 1990, p. xiii). If true, this would mean that that ongoing capitalist development will not eliminate unevenness; rather, it will continually recreate it. Empirically, the historical geography of capitalist modernity would seem to support the latter position.

Uneven development is central to the geographies of capitalism for several reasons. Capitalist firms and states arguably depend upon geographical unevenness to perform functions essential to the ongoing accumulation of capital, such as displacing and ameliorating crisis tendencies (e.g. via the constant provision of new sites for investment) and disciplining workers or states (e.g. via threats to move jobs to lower-wage locations, or punitive disinvestment). More fundamentally, though, capitalist production necessarily results in uneven development, whether or not particular capitalists intend, desire or benefit from it. This is because of the unavoidable tension between the need to invest capital in the built environment in relatively fixed and enduring ways in order to engage in production, and the need for capital to remain mobile in order to circulate as value and remain available for investment in new locations and industries with higher rates of profit. As Smith puts it, ‘The spatial immobilization of capital in its material form is no more or less a necessity than the perpetual circulation of capital as value. Thus it is possible to see the uneven development of capitalism as the geographical expression of the more fundamental contradiction between use value and exchange value’ (1990, p. xv). The concrete implications of this rather abstract formulation are that the process of development in a particular place is very likely to foster conditions that will make it a less attractive location for further investment in the not-too-distant future: wages and ground rents will rise, the workers concentrated there will have increased incentives and means to organize politically, and so on – all meaning that the anticipated rate of profit on future investments there will compare unfavourably to that in less developed locations. Conversely, the consequences of underdevelopment often include conditions attractive to capital and conducive to high rates of profit: high unemployment, low wages and rents, states eager to co-operate and more. Uneven development can thus be seen as the unity of the seemingly opposed, but intimately connected, processes of development and underdevelopment.

Perhaps the critical point regarding uneven development is that there is no reason to expect it to end: capital can move back and forth among places indefinitely in multiple rounds of investment, sequentially building up, abandoning and reinvesting in the same locations. Debates over such dynamics have been central to marxism (see Smith, 1990): Marx himself, as well as Rosa Luxemburg and others, suggested at points that capitalist development depended on the continual incorporation of previously uncolonized areas, and that once that the global expansion of capitalism was complete, it would lead towards a homogenous landscape of capitalist development and the preconditions for international socialism. The end of colonial expansion failed to curtail the development of capitalism, though, calling such a vision into question and leading Lenin and Trotsky to recognize and theorize the evident fact that capitalism could develop via uneven development within areas already internal to capitalism. Underdevelopment came to be understood less as a condition of neglect or exclusion from the international capitalist economy, and more as something actively produced though inclusion in that economy, often on unfavourable terms.

Marxist geography tackled the question of uneven development anew in the 1980s and 1990s, with Harvey (1999 [1982], 2001) and Smith (1990, 1996b) in particular seeking to develop a systemic theory of the geographical dynamics of capitalist development, and they and others endeavouring to delineate more precisely how uneven development works in specific types of settings. Neil Smith has introduced at least two arguments that have influenced much subsequent research in geography. The first, developed with respect to older urban areas and gentrification, suggested that a large rent gap could be identified as an underlying mechanism triggering switches between periods of disinvestment and reinvestment in urban areas (Smith, 1979c, 1996a). The second was that the ongoing production of nature under
capitalism ensures that more and more of the non-human world is transformed by the dynamics of capitalist uneven development (Smith, 1990). These concepts have informed much subsequent research attempting to trace how capital circulates through built and natural environments, constantly recreating and undermining distinctions such as urban versus rural or suburban (e.g. Henderson, 1999; Murdoch and Lowe, 2003; Darling, 2005). Related work on industrial location theory has explored industrial geographies in light of theories of uneven development – theorizing, for instance, the ‘windows of opportunity’ for firms and sectors to dramatically change their geographies (Storper and Walker, 1989). universalism The idea that defining characteristics of phenomena, conceptual definitions or moral, aesthetic or epistemological truths hold for all times and places, transcending their immediate local circumstances (see EPISTEMOLOGY; MORAL GEOGRAPHIES). Such characteristics, definitions and truths are made on the basis of wider practices and theoretical schemes, the justification for which is given by their universal starting point. Plato first made the distinction between universals and particulars. Universals are the general referents to which words such as ‘redness’ or ‘goodness’ or ‘beauty’ refer, whereas particulars are their concrete instances; for example, the red serge jackets of Canadian Mounties, Mother Theresa or a Van Gogh painting. The postwar history of GEOGRAPHY can be read as the history of the invocation of different universals. So, for example, those committed to HUMAN GEOGRAPHY as SPATIAL SCIENCE appealed to the universals of QUANTITATIVE METHODS and RATIONAL CHOICE THEORY; MARXIST GEOGRAPHY looked to the universal of value as defined by the LABOUR THEORY OF VALUE; and HUMANISTIC GEOGRAPHY to a universal HUMANISM. Recent work in the HUMANITIES and social sciences, including human geography, and going under the signs of POSTMODERNISM, POST-STRUCTURALISM and POST-COLONIALISM, criticizes the use of universals, connecting their deployment to systemic power differentials around (for example) GENDER, CLASS and RACE. So, for example, the ‘universal’ SUBJECT of classical humanism turns out to have been bourgeois, male and European, but these markings were unremarked in the vocabulary of universalism to which the IDEOLOGY appealed. Universals are thus another means by which oppression and domination are realized. TB

urban and regional planning The design and institution of specific policies and LAWS to guide land use in METROPOLITAN AREAS (or sub-areas), usually by or at the direction of governments. Urban and regional planning is inherently a spatial activity: the broad goal is to ‘provide for a spatial structure of activities (or of land uses) which in some way is better than the pattern existing without planning’ (Hall, 2002c [1975], p. 3). Planning involves predictive statistical analyses about future growth of population and economies, combined with architectural and landscape blueprints (often in the form of land-use and ZONING maps) for the physical manifestation of such growth in space. Computer technology (especially GEOGRAPHIC INFORMATION SYSTEMS) has transformed planning from blueprints for the future to a notion of ‘a continuous series of controls over the development of [an] . . . area’ (ibid., p. 12).

UTOPIAN ideals for the physical layout and social structure of CITIES and SOCIETIES have existed for centuries (see UTOPIA), but the creation of formal planning as a profession and activity in GOVERNANCE culminated from a series of separate yet interrelated political and social concerns in the nineteenth and twentieth centuries about public health and sanitation, CRIME, POVERTY and, in the USA, immigrant ASSIMILATION (Hall, 2002b [1988]). It is rooted in the utopian ideals of MODERNISM, and a faith in the capacity for scientific and technical reason to achieve the goals of order, coherence and regulation. In the twentieth century planning was institutionalized at different SCALES of government (e.g. federal, state and municipal) to manage the growth and expansion of cities, especially in terms of land use and provision of INFRASTRUCTURE (particularly transportation and utilities). Patrick Geddes and Lewis Mumford were instrumental in reconceptualizing American and British urban or town planning into regional planning in the 1910s and 1920s. In the same period, ZONING was established in the USA, enabling the land-use controls that are essential to planning.

Ebenezer Howard’s design for and realization of his ‘GARDEN CITY’ in Letchworth, England (between 1898 and 1903), was one
of the first explicit attempts at urban and regional planning. One of his primary goals was to seek a balance between industry and nature, a goal shared with the parks movement in the USA, particularly as advocated by Calvert Vaux and Frederick Law Olmsted (Jackson, 1985; Hall, 2002a [1988]). The ‘City Beautiful’ movement was another response against industrialization, but one that focused primarily on physical architecture rather than land use overall (Hall, 2002a [1988]). The architect Le Corbusier’s grandiose visions were influential in the creation of entirely new cities in Brasilia, Brazil and Chandigarh, India (Hall, 2002a [1988]).

With the rise of neo-liberalism, urban and regional planning is increasingly a public-private partnership, with an emphasis in some countries on self-help initiatives (Drakakis-Smith, 1997). The impact of globalization and competition among global cities also curtail the authority of planners working at the urban and regional scale. The ‘pillars’ of modernist planning have been crumbling for at least three decades for other reasons as well (Sandercock, 2003, p. 2). Jane Jacobs (1961) leveled an early and highly influential critique and alternative. More recently, Leonie Sandercock (2003) has charted the life and death of modern planning, outlining alternative progressive, democratic planning practices influenced by feminist, post-colonial and post-modern theory (See Feminism, Postmodernism, Post-colonialism).

Urban ecology Two different perspectives relating to the study of urban environments: the first, drawn from the Chicago school, examines the spatiality of urban land use and social groups; while the second refers to urban nature and an ecosystems approach.

Urban ecology from the Chicago school is part of the broader human ecology tradition. It treats urban land-use patterns as the result of social processes such as competition, segregation, invasion and succession among social groups, resulting in a ‘natural’ spatial order despite constant mobility and expansion of the system (Berry and Kasarda, 1977). Hawley (1950, cited in Berry and Kasarda, 1977) modified this ecological approach to emphasize interdependence among individuals and their activities, and constant adaptation to the physical and social environment (Berry and Kasarda, 1977). Scholars continue to pose research questions relating to human organization and community, urban form and environmental adaptation, but the urban ecology approach as derived from underneath the human ecology umbrella is not dominant. Critiques of the Chicago School’s biological metaphors and lack of specificity in defining key terms, such as ‘environment’ (Berry and Kasarda, 1977, pp. 14–15), contributed to the decline, as has the rise of new approaches to concepts of nature and ecology itself.

The ecosystem perspective – often called urban political ecology – is the contemporary, and dominant, approach to urban ecology (Keil, 2003). It shares with the early ecological approaches recognition of the importance of interdependence, social relations and human-environment relations (Vasishth and Sloane, 2002). But as Wolch, Pincetl and Pulido (2002) point out, the Chicago School ecologies transposed biological metaphors and ecosystem thinking on to human activity and relationships, leaving all conceptualizations of nature as separate from and outside of the urban. Contemporary urban ecology seeks to redress this omission, incorporating nature and non-human species into an approach that recognizes the interdependency and coexistence of social, political and environmental processes and events in the urban sphere. Urban political ecology examines urban and nature as inter-related, mutually constituting dynamics, rather than separate arenas (Keil, 2003). Further, urban political ecology explicitly links urban environments and problems of sustainability to global processes such as capitalism. Urban ecology is one of a growing area of ecological scholarship, analytically linking humans and nature in local-global relations.

urban exploration Involving journeys through CITIES as a means of discovery and the construction of geographical knowledge, the term is often associated with the activities of nineteenth-century social explorers and reformers, who ventured into urban spaces in the ‘heart of empire’ to report on their conditions and bring them to wider public attention. As with cultures and practices of EXPLORATION more generally, such explorations have been subjected to considerable critical attention, which has focused on the colonial DISCOURSES and unequal power relations that framed them, the encounters they involved, and the ways in which their accounts were not simply neutral but had material effects – for example, scripting urban areas as ‘dark’, ‘undiscovered’ and populated by a ‘race apart’ (Driver, 2001a, ch. 8; cf. COLONIALISM; IMPERIALISM). The term has been appropriated for other ends, however. Among those seeking to turn around the colonialist language of exploration has been the radical geographer Bill Bunge, through his urban ‘expeditions’ in the late 1960s and early 1970s as part of the Society for Human Exploration. Based in Detroit and later Toronto, these aimed to be contributive to engaging photographic documentation, and imbued with a sense of play and curiosity, their profile and popularity has expanded rapidly through media attention and proliferating INTERNET sites. Modes of urban exploration have also been important in recent ARTS, cultural and writing practice through projects that seek to engage with city spaces and their potentialities beyond galleries and other formal arts institutions (Pinder, 2005b). Some of these are indebted to the earlier politicized spatial practices of the SITUATIONISTS as well as to longer visionary and literary traditions of urban wandering as they intervene in how spaces are imagined, represented and lived. (See also PSYCHOGEOGRAPHY.)

urban fringe Those areas around urban cores that are functionally or morphologically linked (but not necessarily contiguous) to the urban REGION and have an emerging (sub) urban settlement structure. They tend no longer to be dependent on agriculture alone and do not simply take overflow from urban industrial, transportation or commercial activities in the core. The term is a statistical category. Statistics Canada, for example, defines the urban fringe as including ‘all small urban areas (with less than 10,000 population)’ within census metropolitan areas that are ‘not contiguous to the urban core’ (http://geodepot.statcan.ca/Diss/Reference/Tutorial/UF_tut2_e.cfm).

In the 1980s and 1990s the urban fringe was the focus of much attention, as traditional urban cores lost significance to industrial and commercial competitors in SUBURBS and networked small towns close to METROPOLITAN areas. Terms such as ‘EXOPOLIS’ (Soja, 1992), ‘Zwischenstadt’ (Sieverts, 2003) or ‘EDGE CITY’ (Garreau, 1991) signalled the growing significance of emerging denser nodes in the urban fringe.

urban geography The geographical study of urban spaces and urban ways of being. It was the CHICAGO SCHOOL of sociology, and not geographers, who initiated the study of urban space (Fyfe and Kenny, 2005). Early urban geography was characterized by historical studies that saw physical MORPHOLOGY to be a determinant of urban development, or regional studies that looked at the different relations between towns. By way of contrast, Chicago sociologists studied HUMAN ECOLOGY, gathering data through social surveys and PARTICIPANT OBSERVATION, and producing rich urban ETHNOGRAPHIES. It was not until the mid-1950s that geographers, drawing heavily on sociology and NEO-CLASSICAL ECONOMICS, and on the LOCATIONAL THEORIES of geographers Chauncey Harris and Edward Ullman,
systematized the sub-discipline of urban geography. Over the next 50 years, urban geography advanced to a central position in the discipline. By the 1960s and 1970s, urban geographers had become key players in the QUANTITATIVE REVOLUTION. Urban geographers adopted LOCATIONAL ANALYSIS, the philosophy of POSITIVISM and the methods of SPATIAL SCIENCE as the tools of their trade. The economy of cities was central to their work and a number of urban geographers sought to translate their theories into urban policy prescriptions for the revitalization of deindustrializing cities. The theoretical models associated with this SPATIAL SCIENCE, such as CENTRAL PLACE THEORY, industrial location theory, urban FACTORIAL ECOLOGY and the RANK SIZE RULE, was the backbone of a broadly (neo-)classical school of analytical urban geography. At the same time, there was other work on the city in geography that resitred the orthodoxy of spatial science. Kevin Lynch’s (1960) The image of the city, provided a sort of BEHAVIOURAL GEOGRAPHY that looked at people’s perceptions of the urban environment by analysing their MENTAL MAPS, and prefigured, in radically different form, recent work on the city as text, and the BODY and the city.

By the early 1970s, however, spatial science was being criticized for not explaining the social processes behind the spatial patterns being mapped and modelled, and two alternative theoretical frameworks emerged – one from MARXISM, espousing a radical POLITICAL ECONOMY approach, and the other from HUMANISM, drawing on the PRAGMATISM and the more interpretative methods (as opposed to the MODELS) of the Chicago School. These approaches are evident in two very different books that focused on the city – David Harvey’s (1973) Social justice and the city and David Ley’s (1974) The black inner city as frontier outpost: images and behavior of a Philadelphia neighbourhood. The former rejected liberal assumptions about the city and began to expose the structural logic of CAPITALISM and its role in social inequality; the latter was interested in how individuals experienced the city and the values and meanings they attached to it. Although focused on the city, these books are often seen to be studies in SOCIAL GEOGRAPHY – this mirrors the fact that studies of the urban at this time began to dominate other sub-disciplines, including also CULTURAL GEOGRAPHY, ECONOMIC GEOGRAPHY and POLITICAL GEOGRAPHY and sub-disciplinary boundaries became more blurred. Indeed, patterns of urban social and ethnic SEGREGATION were being analysed by social geographers such as Ceri Peach and Fred Boal.

From the late 1970s, global economic (and, indeed, the associated social) RESTRUCTURING significantly expanded the scope of urban geography. New research agendas emerged looking at financial capital, silicon landscapes, telecommunications networks, the new URBANISM, the new (urban) middle class and GLOBAL CITIES. Research interests moved away from the INNER CITY to the SUBURBS and EDGE CITIES and, indeed, outwards from the metropolitan to the global SCALE. Those that did choose to study the inner city looked at urban revitalization initiatives and festival marketplaces, and began to theorize processes of GENTRIFICATION. The geographical literature on gentrification that was to become so central to urban geography in the 1990s saw its genesis in the mid-1980s with the publication of Smith and William’s (1986) Gentrification of the city. In this edited collection, theoretical debates raged between structure and HUMAN AGENCY. From this point on, urban geographers began to seek a more sophisticated conceptualization of agency in an urban geography that was dominated by political economy. In the late 1980s, Marston, Towers, Cadwallader and Kirby (1989) argued, in a chapter titled 'The urban problematic', that urban geography was suffering from a decline in its vitality due to the crippling historical legacy of outdated approaches, but that it was beginning to move into new areas of research and expertise. In the 1980s, two distinct but overlapping developments – FEMINISM and POSTMODERNISM – began to permeate urban geography. Feminism charged urban geographers to look at the lives of women in the city and to reconsider urban theory in the light of feminist theory (McDowell, 1983), whilst postmodernism forced urban geographers to consider the privileging of one urban theory over another, the social construction of the urban, and the fact that there were differences in the city other than CLASS and RACE/ETHNICITY, such as GENDER, age, SEXUALITY and DISABILITY.

In the 1990s, the import of feminism and postmodernism forged the CULTURAL TURN in social geography and the subsequent emergence of the new CULTURAL GEOGRAPHY in the discipline as a whole. As a result of urban geography’s relatively greater attachment to quantitative and applied work, the strong influence of political economy, and its long tradition of empirical and practical research, it embraced the cultural turn relatively late. This state of affairs was nowhere more
apparent than in the debates over gentrification that dominated urban geography at this time. In the early to mid-1990s, debates over the causes of gentrification became stalemated between Neil Smith’s political economy production explanation and David Ley’s humanist consumption explanation – demonstrating to many geographers the necessity of challenging and (re)negotiating such metanarratives. In some respects, however, the slower import of the cultural turn into urban geography was fortuitous, as it meant that urban geography was able to avoid many of the allegedly immaterial excesses in which social and cultural geography became embroiled (Lees, 2002). Over time, interest in the identity politics of difference in the city grew, culminating in the notion of ‘cities of difference’ (Fincher and Jacobs, 1998). The hegemony of human-centred urban theories was questioned so that non-human actors, such as animals, began to be included in urban theory, leading Wolch, West and Gaines (1995) to construct a trans-species urban theory. And urban geographers began to integrate the study of language and culture into urban geographical analysis much more fully.

In many ways symptomatic of the fact that more or less everything and everywhere had by now become urban and that urban geographers identified themselves less as urban geographers and more as feminist, post-modernist, Marxist or population geographers, in 1993 Nigel Thrift proclaimed an ‘urban impasse’ – the loss of the urban as both a subject and object of study. Nevertheless, refocusing on the urban as a subject and object of study, there was a proliferation of work in the 1990s on global cities and on global economic restructuring. Certain cities emerged as the command and control centres of global capitalism – cities such as New York, London and Tokyo. Sassen (1991) argued that such global cities are characterized by an hourglass socio-economic profile, with growth at the top and bottom ends and decline in the middle ranks. Hamnett (1994) refuted this claim, arguing that the outcomes of globalization in cities are mediated by national and city specifics. Rather than focusing on individual cities, Beaverstock, Smith and Taylor (2000) examined the networks that connect such world or global cities. Drawing on sociologist Manuel Castells’ (1996b) The rise of the network society, they argued that global cities should be studied less as places and more as a process located in a networked space of flows.

The notion of global or world cities, though, is very much from the point of view of the West. And urban geographers are increasingly critical of the hegemony of the West in urban theory, evidence of the impact of post-colonialism on urban geography. Countering this hegemony, urban geographers are now complicating the dichotomy between the urban north and south in terms of both urbanizations and urbanism, and between First World and Third World cities. Unlike McGee’s (1971) pioneering work on Third World cities, which called for urban models to be sympathetic to the cultural and historical backgrounds of such cities, contemporary work on Third World cities argues that in an era of globalization a process of convergence has emerged such that there should now be a single urban discourse that is inclusive of all cities. Chakravorty (2000), for example, uses Calcutta to demonstrate concerns about Third World cities being viewed separately from the development of First World cities, and argues that urban development in one part of the globe cannot be understood without reference to urban development elsewhere in the world. This idea that urban processes are now converging around the globe can also be seen in the gentrification literature. For gentrification is now seen to be a process of ‘new urban colonialism’ occurring all over the globe from Brazil to Poland to Japan. Also linked to global economic restructuring, post-socialist cities have come under the lens of urban geographers. There has been some research on post-socialist eastern and central European cities, but more recently there has been a proliferation of research on the ‘market socialism’ of contemporary Chinese cities. Perhaps not surprisingly, it seems to be the economically successful cities that attract the most research. Jenny Robinson (2004) asks how it is possible to write across diverse urban contexts, which are distinctive and unique, but also interconnected and part of widely circulating practices of urbanism. She argues that suggestions that growing convergences between cities of the ‘North’ and the ‘South’ make them more comparable are a little misleading, and that the ambitions of post-colonialism suggest that simply universalizing Western accounts of cities is inappropriate. Instead, she suggests that if we are to engage in a properly comparative or transnational urbanism we need to excavate and disturb some long-standing and frequently taken-for-granted assumptions about how urban geography deals with differences among cities. She argues that two key concepts have
led urban studies to this impasse – the concepts of MODERNITY and DEVELOPMENT. These have to be unpacked and urban geography allowed to learn from the diverse tactics of urban living around the world.

As urban geography entered the twenty-first century, Michael Dear (2000) proclaimed that ‘the dominance of the Chicago model is being challenged by what may be an emergent “LOS ANGELES SCHOOL”’. Like the Chicago School, the LA School is not a geography school; rather, the LA School is made up of scholars largely, but not solely, based in the Graduate School of Architecture and Urban Planning at UCLA, even if many of those scholars are in fact geographers. Where Chicago was seen to be the exemplar of the old, modern, industrial city, Los Angeles is touted as the exemplar of the new, postmodern, post-industrial city.

With its decentralised urban sprawl, gated communities and edge cities, LA is (re)presented as the prototypical postmodern urban landscape – multinucleated, disarticulated and polarized. The city has become so unpredictable that the School represents it as a centreless urban form, a keno gameboard in place of the Chicago School’s concentric rings of industry and settlement. Yet this new representation is still subject to the forces of capitalism. Dear even invents a new language for the new urban processes to be found in LA to signify the distinctiveness of postmodern urbanism – words such as ‘cybergoisie’ (elite executives and entrepreneurs), ‘proto-surfs’ (marginalized surplus labour), ‘commodities’ (commodified communities) and so on. Most geographers have been critical of claims about the PARADIGMATIC status of Los Angeles. Nijman (2000) has argued that Miami, which also experiences the same issues, but at a smaller and as a result more intense scale, is more deserving of the status of quintessential postmodern city; whilst other authors have criticized the ‘thin’ methodologies behind the LA School’s research. In time to come, ‘postmodern urbanism’ may become one of the definitive statements of the LA School, ‘notable more for its intellectual bravado than theoretical displacement’ (Beauregard, 1999): on the other hand, all that is not solid also melts into air.

At the same time as urban geography has taken on board the interpretative turn, it has begun to move in another direction too, towards what Batty (2000) calls ‘the new urban geography of the third dimension’.

The approach is quantitative rather than qualitative, and studies use data sets to detect fine-scale, intensive and extensive, patterns in metropolitan areas. In this work, GIS and modelling are the central techniques not textual, semiotic or DISCOURSE analysis. This reminds us that urban geography covers a large community of researchers, using different approaches to study the urban. In contrast to the LA School’s representational turn, Amin and Thrift’s (2002) Cities: reimagining the urban demonstrates a non-representational turn (see NON-REPRESENTATIONAL THEORY). Amin and Thrift argue that cities are too intricate and as such are difficult to generalize, thus voicing the limits to REPRESENTATION encountered in the HERMENEUTIC tradition. They argue that the city is a spatially open entity, cross-cut by various mobilities – people, information, commodities – and as such to properly engage with the ‘multiplexity’ of the city we have to recognize that cities are the ‘irreducible product of mixture’. This way of looking at the city has implications for how we define urban life and for a new politics of the city.

In recent years, urban geographers have become more confident of their position again. Aitken, Mitchell and Staeheli (2002) maintain ‘that [urban] geographers are [now] at the forefront not only of understanding contemporary urban space, but also of imagining and mapping its futures’. No doubt connected to this new confidence, urban geographers have begun to reflect on the postwar development of urban geography, to which the numerous special issues devoted to this in the journal Urban Geography over the past few years attest.

Urban geographers have also begun to re-engage more clearly with questions of urban policy, and to promote an urban geography that critically evaluates urban theory and methods and has a social change and/or justice agenda. This ‘new’ urban geography has practical relevance and resonance, and the material engages with, and works through, substantive political engagement.

urban nature A combination of seemingly contradictory terms: conventionally, where there is the city, there cannot be NATURE. In the past, urban life was decidedly built in contradistinction to rural and agricultural forms of life. Nature, like ‘uncivilized’ forms of life, was banned within the walls of cities. Urbanization, in fact, has often been understood as a process of human distancing from first nature (Lefebvre, 2003 [1970]). In cities, nature became a residual or artificial category limited to parks, zoos and urban – mostly ornamental – gardens. Still, twentieth-century urban theory was strongly influenced by the ways in which nature was understood by modern science. The Chicago School of urban sociology organized thinking on social structures and processes around notions taken from evolutionary biology and ecology (see Human Ecology). These metaphors were so strongly criticized by human geographers and urban sociologists (Harvey, 1973; Castells, 1977; Gottdiener, 1985) that it became extraordinarily difficult to conceptualize ‘urban’ and ‘nature’ together. The impasse was broken in the 1990s, when scholars in political ecology began to question the non-urban focus of their field and its search for ‘nature’ outside of cities. Some urban political ecologists began to question the non-urban focus of their field and its search for ‘nature’ together. The impasse was broken in the 1990s, when scholars in political ecology began to question the non-urban focus of their field and its search for ‘nature’ outside of cities. The new field of urban ecology studies the specific bio-physical natures found in urban settings (Breuste, Feldman and Uhlmann, 1998). Planners and designers have taken nature into consideration when altering urban form (Hough, 2004). Urban social geographers at the same time began to take a fresh look at urban nature. Signature studies of individual cities such as Chicago (Cronon, 1991), Los Angeles (Davis, 1998) and New York City (Gandy, 2002) placed nature in a continuum of societal relationships rather than separate from it. Social justice concerns were widened to include issues of urban environmental justice (Harvey, 1996; Bullard, 2000). By the mid-1990s, the notion of ‘zóopolis’ was added to acknowledge the presence of animals inside cities (Emel and Wolch, 1998; see animals). Going even further, urban geographers have now begun to speak about ‘trans-human urbanism’ to express the collapsing of boundaries between human and non-human nature(s) in cities (Braun, 2005). Originally used in the context of studies on urban sustainability (Newcombe, Kalma and Aston, 1978), the concept of ‘urban metabolism’ has now become central to critical explorations of urban nature (Heynen, Kaika and Swyngedouw, 2006). Urban political ecology in both the global south and the (post-)industrial north has begun to acknowledge the importance of thinking urban nature as part of, rather than different from, social and cultural processes in cities.

urban origins Most archaeologists, geographers and historians recognize five distinctive cultural hearths in which cities first emerged:

- Mesopotamia (modern Iraq) (3500 BCE);
- the Nile Valley (Egypt) (3000 BCE);
- the Indus Valley (modern India/Pakistan) (2300 BCE);
- the Huan He (Yellow River) Valley (China) (1500 BCE); and
- Meso-America (600 BCE).

The sites and locations differ, but so too did the process. In Mesopotamia urban trajectories were long drawn-out, for example, whereas in much of the Indus valley the transition to a DISTINCTIVELY ‘urban phase’ was much more rapid (Possehl, 1990). Gordon Childe (1946, 1950) claimed that the formation of cities was so dramatic that it constituted a veritable urban revolution, whereas Lewis Mumford (1963) insisted that early cities emerged through the concentration and condensation of cultural forms that pre-existed their crystallization and so preferred to speak of an urban implosion.

There has also been a lively debate over the importance of religion: Mumford insisted that it was ‘only for their gods’ that people
would have been mobilized on such a scale and for such extensive periods of time, and Paul Wheatley (1971, 1972) saw the city as not only a sacred space but also a cosmogram, 'the pivot of the four quarters' (see also Carl, Kemp, Laurence, Coningham, Higham and Cowgill, 2000). Others, reactivating Childe's materialism, insisted on the importance of the production and concentration of a surplus within a supra-local economy dominated by redistribution (Harvey, 1973). It may be, however, that the distinction between 'religion' and 'economy' owes more to our own language-systems and analytical distinctions than to the world-views of the people who made these extraordinary transitions. Focusing on the king as 'the dominant locus of spatial production in southern Mesopotamia by the Ur II period', Smith (2003b) argues that the king was both the guarantor of the fertility of the land, and as such responsible for constructing many of the large irrigation canals required for agricultural production on the arid plains of Sumer (see Adams, 1966), and also guarantor of the security of the city, and as such responsible for propitiating the gods through a monumental architecture of ziggurats and temples (see Gates, 2003). In short, the choice between 'gods' or 'granaries' may be a false one (see table).

Most urban geographers and historical geographers have seen the study of urban origins as little more than a platform from which to explore other, to them more pressing, issues about the nature of urbanism (Carter, 1977). But research into the origins of urbanism – in the canonical sites and in others – has been revitalized in recent years by new excavations, new techniques of remote sensing and reconstruction, and new ideas (in particular a move beyond the 'new archaeology' of the 1970s, which was closely modelled on spatial science, to a closer co-operation with anthropology and a correspondingly greater interest in economic, cultural and political processes). Three debates have been particularly important in opening up the trajectories through which cities first emerged in different cultures around the world:

- `Decoupling` urbanization from agriculture. Trading on two major excavations at Çatal Hoyuk in Anatolia by James Mellaart and Ian Hodder (see Hodder, 2006), and on a thought-experiment by Jane Jacobs (1992 [1961]) – in which Çatal Hoyuk becomes 'New Obsidian' – Edward Soja (2000b) proposed that 'Rather than an agricultural surplus being necessary for the creation of cities, it was cities that were necessary for the creation of an agricultural surplus.' It is important to recognize that the relations between subsistence, surplus and city formation were many-stranded, but the rise and fall of cities was often intimately connected to changing ecological regimes and it seems unlikely that such a global reversal can be sustained.

- `Decoupling` urbanization from state formation. The first cities were closely associated with the invention of writing systems, but these were usually inventories of stocks and flows of goods pivoting on the temple (rather than chronicles of kings) and so do not necessarily tie the formation of the city to the emergence of a centralized state (see Yoffee, 2005). In South Asia, for example, Smith (2006a, p. 109) shows that cities were tied in to larger economic systems and were 'long-lived regardless of the political configuration in which they were located'.

- `Decoupling` urbanization from elites. Cities, then as now, were more than monumental performances of power. Many scholars do still accept that the first cities 'stressed the insignificance of the ordinary person, the power and legitimacy of the ruler, and the concentration of supernatural power' (Trigger, 2003, p. 121). But Smith (2006a) insists on 'the willing presence of a population' – as Mumford (1963) had it, the first cities were 'magnets' as well as 'containers' –

urban renewal  A term referring to a range of strategies aimed at reshaping urban landscapes and remedying social and economic problems associated with run-down inner-city neighbourhoods. These strategies, generally promoted by state actors and business interests, are frequently questioned and/or directly opposed by residents of central-city neighbourhoods. Nevertheless, they generally result in massive landscape change and the displacement of large numbers of existing residents. Debate around urban renewal tends to focus on the interests that drive it, the specific strategies employed to achieve it, and the impacts of renewal strategies on targeted neighbourhoods and their residents.

Urban renewal has a long history, with antecedents in the Haussmannization of Paris in the 1850s and 1860s, for instance. Yet, it generally refers to massive state-led building projects in the wake of the Second World War in Europe and in North America. The first phase of postwar urban renewal, in the 1950s and 1960s, was characterized by massive public works projects that razed established neighbourhoods in favour of new commercial districts, housing projects and highways in the name of modernization (Berman, 1983). These projects were conceived and driven by powerful state bureaucracies and, in some cases, by powerful individuals such as New York’s Robert Moses. Bureaucrats wielded their power not merely to address self-evident urban problems but to actually constitute specific neighbourhoods, and by extension, certain people and ways of life, as problems to be remedied. Narrow definitions of ‘blight’ were central to the identification of areas in need of renewal; a fact that highlights the often problematic combination of power, discourse and space in urban renewal (Weber, 2002).

Growing criticism of these strategies – the negative impacts of which largely fell on the poor and racial minorities who were forcibly displaced – led, by the 1970s, to a wider set of renewal policies. These new approaches responded to critiques, levelled by people such as Jane Jacobs (1992 [1961]), of the high-handedness of planners and the deadened nature of the new spaces they produced.

In the next three decades, individual urban renewal projects have been marked by combinations of strategies, the relative weight of each being governed by the specific context in which each project is operationalized. Massive state-led redevelopment projects continue in some contexts while, in others, the refurbishment and preservation of older neighbourhoods, often with the involvement of neighbours in localized, participatory planning processes, has emerged as an important approach. These strategies have been accompanied by the emergence of public-private partnerships as a business-oriented, often property-led strategy, which still dominates a great deal of urban renewal and is exemplified by large-scale urban developments across Europe (Moulaert, Rodriguez and Swyngedouw, 2003).

Contemporary studies emphasize the role that the arts, tourism, mega-events (such as the Olympic Games) and gentrification play in urban renewal and the uneven benefits that stem from these strategies. Others highlight alternatives to dominant public-private approaches, involving various forms of community development – from co-operative ownership models for housing to alternative methods of investing in inner-city communities – all of which indicate the ongoing tension and struggle that accompanies attempts to define problem areas in cities or to formulate and implement equitable solutions to those problems.

urban social movement  Collective action based on grievances that originate or are physically manifest in urban areas, such as a lack of public services, in which the state is the primary target for activism. A debate in the 1980s focused on whether there were distinctively urban social movements, and whether these were necessarily progressive in their goals (Fincher, 1987). Castells (1983) argued that urban social movements were, more so than other social movements, oriented to grievances around collective consumption, rather than around class. Yet other scholars pointed out that some urban social movements address conflicts in the sphere of production (Fincher, 1987).
A central theme of urban social movements is activism against or seeking a response from the state, which is held responsible for uneven provision of public services (Fincher, 1987). Castells (1983) identified urban social movements with very different grievances, directed at or limited by their focus on the state. Claims relating to collective consumption were exemplified by activism in France over provision of housing (Castells, 1983). Other urban social movements incorporated claims such as those around identity politics. Activists in San Francisco, for example, sought legitimation and social rights requiring state action. Castells (1983, p. 171) found these latter movements to be limited in their membership and scope, because of their adoption of social categories (identities) that defined and divided groups according to state administrative frameworks. Nonetheless, urban social movements in general could achieve some success, which may have contributed to their institutionalization, and a decline of the movements themselves (Castells, 1983; Fincher, 1987).

More recent scholarship has tended to examine social movements as a whole, with urban social movements viewed simply as territorial manifestations of broader identity, class and social justice conflicts (McAdam, Tarrow and Tilly, 2001). Activists in third world cities continue to seek redress for inequalities in urban service delivery, illustrating the salience of concerns oriented to collective consumption (Mitlin and Satterthwaite, 2004). Many challenges to state service provision, however, are occurring on a multinational, multi-scale level, as part of broader anti-globalization efforts.

**urban system** A set of interlinked cities and towns set within a specific territory (e.g. the nation or the globe). The concept owes its origins to central place theory and systems analysis approaches to economic functions, and functional divisions of labour, within national territories (Berry, 1964). While the evolution and contemporary characteristics of national urban systems remains a focus of research, a great deal of urban systems-oriented scholarship now focuses on the global scale. Contemporary global cities or world cities research seeks to understand how a network of cities, stretched unevenly across the world, organizes the spaces of the global economy (Taylor, 2004).

**urban village** A concept developed by Gans (1962) in his *Ethnography* of an Italian immigrant neighbourhood in central Boston. He identified elements of a coherent local, or ‘village-like’, social world – including ethnicity, kinship, friendship and values – that reflected and bolstered residents’ identity and helped maintain it over time. Spatially, this social world is located in a clearly defined urban neighbourhood where much of the population has long-standing ties – an urban village. This argument was set against the understanding, within urban ecology, of urbanism as leading to individuals’ withdrawal from intimate social interactions.

Gans (1962).

**urbanism** Three common definitions for this highly contested term can be distinguished:

1. The typical way of life of people who live in a city or town. In this first sense, the concept is usually traced back to Louis Wirth (1938), a Chicago school sociologist who witnessed and described urbanization in Chicago in the early twentieth century as a process of change to the moral order and the decline of community. The division of labour and sociocultural and socio-economic diversification lead to both fragmentation of individuals’ lives in cities and to the normal expectation of living in the proximity of ‘unknown others’. Using the criteria of size, density and heterogeneity, Wirth claimed the specificity of ‘urbanism as a way of life’. Often, this quality of urbanism is confused with the notion of urbanity, which ascribes characteristics such as sophistication, refinement and courtesy to individuals or communities.

2. The study of life in cities and towns. In this second sense, urbanism combines a scientific method of urban enquiry and an often linked practice of socio-spatial engineering (planning) typical of complex modern societies.

3. Urbanism now often refers to the way people live more generally. Magnusson (2005) is
only one of a succession of commentators who, since Lefebvre (1970 [2003]) foresaw a modern ‘urban revolution’, has claimed that it is ‘only recently that preponderantly modern urban societies have emerged’. The traditional split of town and countryside has been eliminated. As society becomes more urbanized, the city disappears as the distinct object of enquiry and practice, and urban society overall becomes the object of scientific enquiry and policy action. Critics have argued that this is both an ethnocentric and a teleological use of the term, since it equates urbanism with (and by implication normalizes) a model specific to the global north. Thus Robinson (2004, p. 710) insists: ‘This phantasmagoria of urban experiences in the west, this western “modern,” often fails to capture the inventiveness and creativity of people in poor cities, more often tied to the heroic (tragic?) resilience of urban dwellers in the face of extraordinary difficulties, rather than to the creative potential of city life.’

French philosopher Henri Lefebvre (2003 [1970]), arguably the most influential urban theorist of the past fifty years, was critical of the ideological and state-centric qualities of urbanism as a state-led project of modernization: ‘Urbanism . . . masks a situation. It conceals operations. It blocks a view of the horizon, a path to urban knowledge and practice. It accompanies the decline of the spontaneous city and the historical urban core. It implies the intervention of power more than that of understanding. Its only coherence, its only logic, is that of the state – the void. The state can only separate, disperse, hollow out vast voids, the squares and avenues built in its own image – an image of force and restraint’ (ibid., pp. 160–1). This state-centred urbanism militates against the possibilities of the urban and against the promise of the right to the city in urban society. In Lefebvre’s own notion of an urban society, which now encompasses the globe, urbanism in this sense will ultimately need to be critiqued and overcome to make way for liberated urban everyday life.

If urbanism is our way of life more generally, it can also be used as a prism through which human societies and their futures can be understood. The postmodern urbanism of Los Angeles was discussed in this manner during the 1980s and 1990s (see Los Angeles School). In the same sense, commentators have looked at other cities more recently as windows into a common future: ‘Dubai is an extreme example of urbanism. One of the fastest growing cities in the world today, it represents the epitome of sprawling, post-industrial and car-oriented urban culture. Within it, large numbers of transient populations are constantly in flux’ (Katodrytis, 2005). The term ‘urbanism’ has of late also been used in compound phrases to describe either real developments in the constitution of cities or normative prescriptions on how to build (better, more sustainable, more liveable) cities. Among the former is the term ‘transnational urbanism’, popularized by Michael Peter Smith (2001a), who believes in the establishment of cities as places through multifarious social relationships in spaces across national borders (see transnationalism). Among the latter, the term ‘urbanism’ has now been resuscitated by the followers of the architectural style and practice of New Urbanism which, with its higher than usual densities and architectural features such as front porches and back alleys, is ostensibly meant to be a realistic answer to urban sprawl in North America. Observers have called this a ‘new suburbanism’, which invokes notions of density and residential community believed absent from common suburban forms of urbanism. (Lehrer and Milgrom, 1996). Similarly, Timothy Luke has appealed for ‘contemporary urbanism as public ecology’, which puts ecological issues into the centre of the urbanist project today (Luke, 2003).

Urbanization John Friedmann (2002) differentiates three meanings of urbanization. The most common use of the term is demographic (see demography) and it refers to ‘the increasing concentration of people (relative to a base population) in urban style settlements at densities that are higher than in the areas surrounding them’ (p. 3). The experience and expectation of human demographic change is ultimately the complete statistical urbanization of the world. Demographic urbanization is tied to an increase in the complexity of social life (Lefebvre, 2003 [1970]; see also urbanism). Distinct patterns and configurations of human settlement structure growth of cities: suburbanization, exurbanization, new urbanism, metropolitanization and the emergence of city-regions. Density is not always part of urbanization, as urban regions sprawl across wide expanses in emerging forms of settlements as diverse as suburbs, excluded gated
COMMUNITIES in natural settings and squatter settlements (see SQUATTING).

A second notion of urbanization is economic. Friedmann makes reference here to ‘economic activities that we normally associate with cities’ (2002, p. 4). While this traditionally would exclude ‘rural’ activities such as agriculture, forestry, fishing or mining, Friedmann reminds us that many of these activities are directly related to urban forms of capitalization and organization. This observation is shared by Lefebvre, who notes: ‘The urban fabric grows, extends its borders, corrodes the residue of agrarian life. This expression, “urban fabric,” does not narrowly define the built world of cities but all manifestations of the dominance of the city over the country. In this sense, a vacation home, a highway, a supermarket in the countryside are all part of the urban fabric’ (Lefebvre, 2003, pp. 3–4). Economic urbanization leads tendentially to the disappearance of ‘residual’ rural activities and ultimately to ‘the erasure of the traditional category of rural’ (Friedmann, 2002, p. 4: cf. RURAL GEOGRAPHY).

The third meaning of urbanization is sociocultural and ‘refers to participation in urban ways of life’. This implies the embrace by populations of URBANISM as a way of life. While it is possible to identify certain developments, such as literacy, universally with sociocultural urbanization, Friedmann cautions against equating CIVILIZATION with urbanization in the tradition of the CHICAGO SCHOOL (see also Robinson, 2004). Friedmann is also quick to point out that ‘sociocultural urbanization is a dimension that, like the economic, is no longer exclusively associated with the city as a built environment’ (p. 5). While cybercafés clearly are nodes in virtual deterritorialized NETWORKS, erstwhile urban practices such as certain modes of communication are now found in the most remote parts of the world.

Friedmann employs the term ‘the skein of the urban’ to describe ‘a new global TOPOGRAPHY of the urban, which steadily advances across the surface of the earth’. Its ‘vertical dimensions are layered [such that] demographic, economic, and sociocultural urbanizations do not necessarily coincide in space’ (2002, p. 6). The nineteenth- and twentieth-century narrative of urbanization as MODERNIZATION has been called into question since the 1980s, when GLOBAL CITY researchers detected new societal cleavages even in Western cities such as Los Angeles and New York City. Mike Davis’ influential text City of quartz (1990) presented a dystopian view of the globalizing Pacific Rim boomtown Los Angeles. In the global SOUTH, urbanization now commonly comes with underdevelopment. The emergence of huge agglomerations – for instance, in some African contexts – has led to two counterposed narratives of urbanization: ‘The first is an eschatological evocation of urban apocalypse: POVERTY, VIOLENCE, disease, political corruption, uncontrollable growth and manic religiosity . . . In this nightmare vision, the city is on the brink of a cataclysm brought about by civil strife and INFRASTRUCTURAL collapse’ (Gandy, 2005, p. 38). A second view is more upbeat and focuses ‘on the novelties of the city’s morphology . . . as the precursor to a new kind of urbanism, hitherto ignored within the teleological discourses of Western modernity; one which may be perfectly adapted to the challenges of the twenty-first century’ (ibid., p. 39).

Considerable controversy has now ensued as to the way in which urbanization has to be understood in a global context. Some have visualized global urbanization processes in terms of new hierarchies and networks, detected as a new class of GLOBAL CITIES or WORLD CITIES. Others have resisted this narrative as Western and potentially imperialist, and have suggested models of global urbanization less tied into notions of supremacy of certain urban centres (Marcuse and van Kempen, 2000). Differences between urbanization in the global North and the global South seem to be getting more pronounced, with rates of urbanization higher in AFRICA, ASIA and LATIN AMERICA than in EUROPE and North America. And even inside larger REGIONS and among urban areas that appear similar on the surface, differentiation occurs. Terry McGee, for example, who has identified several distinctively ASIAN features of urbanization – dominance of the population giants; immense urban increments; the prominence of megacities; and uneven globalization – has also pointed to an internal ‘two-tier structure of Asian urbanization’. Using Seoul, Korea and Dhaka, Bangladesh, as examples, he presents ‘two extremes’ of challenges of current urbanization in Asia: one economically successful, and the other not (McGee, 2001). Similarly different models of urbanization can be identified comparing seemingly similar types of cities on different CONTINENTS in the South. Drawing on her research on African cities, Jennifer Robinson (2006) argues against ‘propagating certain limited views of cities and thereby undermining the potential to

The term was mobilized in a second sense by Balkan scholars and architects to condemn the way in which Serbian armed forces in the war of the 1990s targeted the architectures and spaces of Dubrovnik, Sarajevo and other cities that were most visibly identified with a history of religious, ethnic and national pluralism and heterogeneity in what rapidly became the former Yugoslavia (Coward, 2004; see also ETHNIC CLEANSING). Since then, the analysis of urbicide through military violence has been extended both historically and geographically. Scholars have explored what W.G. Sebald called the 'natural history of destruction', the campaign of British and American strategic bombing of German cities in the Second World War, in exactly these terms (see Mendieta, 2007), for example, while Graham (2003), Gregory (2004a), Weizman (2007) and others have analysed how Israeli armed forces have deliberately destroyed the collective infrastructure of Palestinian cities as part of their attacks on the Occupied Territories since 2002.

The two streams of work, the economic and the martial, forcefully collide in discussions of URBANISM in the global SOUTH, where Goonewardena and Kipfer (2006) have identified a 'post-colonial urbicide' under the sign of a new IMPERIALISM (cf. Schwartz, 2007). These later studies strongly suggest that urbicide is about more than the hollowing out of urban economies, the destruction of MEMORY or the erasure of the physical traces of past communities, important and injurious though these are. Coward (2006; see also 2007) follows Martin Heidegger to argue that 'there is more to the constitution of a polis than the gathering of anthropos': in other words, the physical fabric of the city is not incidental to, but constitutive of the possibilities of political community. In destroying this relational space, urbicide targets the possibility of political community and the very provocation of DIFFERENCE – of heterogeneity – that is at its core. Seen thus, urbicide is a version of political VIOLENCE that is not 'merely' corporeal and material, but also profoundly existential: 'Urbicide is a politics of exclusion aimed at establishing the fiction of a being-without-others' (p. 434) (cf. GENOCIDE).

Suggested reading

urbicide Literally 'killing cities', urbicide refers to the intentional attempt to erase or destroy a city or cities for political purposes. The term has two main origins.

One lies in the critique of modern urban planning. Building on the work of architecture critic Ada Louise Huxtable and her 'Primer on Urbicide' (Huxtable, 1970), Berman (1996) used the term to object to modernist redevelopment strategies in American cities and their violent substitution of soulless abstraction for vibrant traditional streetscapes. Echoing Berman, Merrifield (2004) invoked the same concept in his analysis of the situationists’ resistance to comprehensive redevelopment in Paris in the 1970s.

The term was mobilized in a second sense by Balkan scholars and architects to condemn the way in which Serbian armed forces in the war of the 1990s targeted the architectures and spaces of Dubrovnik, Sarajevo and other cities that were most visibly identified with a history of religious, ethnic and national pluralism and heterogeneity in what rapidly became the former Yugoslavia (Coward, 2004; see also ETHNIC CLEANSING). Since then, the analysis of urbicide through military violence has been extended both historically and geographically. Scholars have explored what W.G. utopianism A theory of ethics originating in the eighteenth-century Britain, prescribing the greatest good for the greatest number. The good is defined by acts that promote happiness, satisfaction or pleasure of the immediate actor and those affected by the act (and making utopianism part of a larger philosophical approach known as consequentialism). Utropians further assume happiness is quantifiable, thereby allowing calculation over an entire population: the world is as good as it can ever be when collective pleasure is maximized. Jeremy Bentham (1748–1832) developed the theory and John Stuart Mill (1806–73) elaborated it. Both intended utopianism to bolster their favourite political philosophy, LIBERALISM: only when people are free to choose will the greatest good for the greatest number be achieved (Mill’s ‘liberty principle’). Criticisms of utopianism are legion and include an
inability to quantify happiness (Bentham’s ‘felicific calculus’ is chimerical), that different people’s happiness is incommensurable, that the consequences of an action may take a very long time to figure (when asked in the 1980s what he thought of the French Revolution, Chou En-lai said, ‘It is too early to say’), and a fixation on consequences at the expense of intentions (good utilitarian acts may be carried out for monstrous reasons). Utilitarianism only lightly brushed geography. A form of utilitarianism was found in the theory of neo-classical economics that was briefly taken up in economic geography.

Suggested reading

utility theory The basis of neo-classical economics, which rests on the doctrine of consumer sovereignty and an ideological belief in both individualism and libertarianism – that individuals are the best judges of their own needs. A consumer’s utility function is identified based on either assumed or revealed preferences and predicts choices, constrained within the available budget (cf. revealed preference analysis). Utility theory has provided the base for much work on travel behaviour and the choice of shopping centre to patronise, referring to destination, modal split (choice of travel mode), and choice of route (cf. discrete choice model).

Suggested reading

utopia Conventionally refers to an ideal society, state or commonwealth in which the problems of the present have been transcended. This is often projected as an imaginary world in another space or time, as implied by the roots of the term coined by Thomas More in his 1516 book Utopia, which plays upon the Greek words eu-topos (‘good place’) and ou-topos (‘no place’). Colloquial usage tends to present utopias as impossible social and political schemes, and hence a domain of escapism, impractical dreaming or authoritarian attempts to construct perfect societies. Yet utopias take many different forms and have a variety of functions, meaning that the concept is highly contested (Levitas, 1990). Utopias find expression in fictional depictions of the good society in literature, film or other media; in experiments to establish ideal communities; in the desire for radical change expressed in many political struggles as well as visions, theories, plans and performances; and, according to some commentators, in an array of everyday activities that anticipate better worlds.

Geographical concerns are central to utopia, as its etymology suggests, with many utopias being set in remote locations or based on spatial designs for cities, architecture, landscapes or environments. These utopias typically express a belief in the power of space to shape human activities, whereby an ordered space becomes a means to contain social process, exclude historical change, and ensure harmony and stability (Porter and Lukermann, 1976). Such a spatial emphasis is apparent in the long association between utopia and cities, and in the influence of utopian thought on urbanism (Pinder, 2005). Projecting different spaces can defamiliarize and challenge what exists, allowing imaginative exploration of alternative ways of living and being. Such utopias may function to provoke, to open senses of possibility. Their imaginative failure may also be of interest, in terms of what it reveals about current limitations and constraints. Yet attempts to realize utopias based on static spatial forms have been fraught with problems and contradictions, especially concerning their authoritarianism, required to fix geography and freeze history to create this ideal realm, and the need to reconcile this with the social processes involved in their materialization (Harvey, 2000b). The particular interests driving their visions of order have thus come under critical scrutiny (Pinder, 2005c).

Recent years have witnessed many claims about the ‘end of utopia’, precipitated by events such as the collapse of communism regimes and by claims that utopian thought is necessarily authoritarian if not downright dangerous. Yet some geographers have argued for a revitalization of utopianism to counteract pronouncements that ‘there is no alternative’, and in the process sought to reconceptualize utopias not in terms of blueprints but in more open and process-oriented ways. For the utopian is a vital moment in critical theory. Benhabib (1986, p. 226) identified the task of critique as the pursuit of both the explanatory-diagnostic and the anticipatory-utopian, but for the most part even critical human geography has shown more of an interest in analysis and prescription: witness the speed at which discussions of Harvey’s (1973) Social justice and the city moved away from the first two words of the title, with their
intimations of ethics and politics, and fastened on the last two. But Harvey (2000b, p. 196) has now returned to these themes to advocate a ‘spatiotemporal’ or ‘dialectical utopianism’ that is ‘rooted in our present possibilities at the same time as it points towards different trajectories of human uneven geographical developments’. While he still insists on the need to define choices and confront issues of closure so as to define ‘that port to which we might want to sail’, other critics, some influenced in particular by feminism and by critical debates within utopian studies, have emphasized a partial and fluid approach to utopia. This gives a central role to desire and to moving beyond present limits into spaces and futures that are necessarily as yet unknown.

**value-added** A process that adds value (as reflected in price) to some commodity. Typically, value is added when labour is applied to a material, transforming it into something more useful (cf. MARXIST ECONOMICS). Value can be added sequentially, at different stages in the production process, as material is turned into a component, which is added to others to make a finished article, which is then packaged and marketed, for example. A value-added tax usually applies a fixed percentage to the price of a good or service; this discriminates against poorer people, who pay the same tax as the rich when they purchase the same thing.

**values** The principles or standards informing individual or group ideas and beliefs. Geographers have considered values held by both individual geographers concerning their subject-matter, and by individuals and groups concerning SOCIETY and NATURE. The evolution of debate over values in geography reflects different associations of the term, whether social, economic, political, environmental or moral. There is, however, common rejection of the separation of fact from values; in particular, the promotion of fact as self-evident and value-free in EMPIRICISM.

Values were a central question for HUMANISTIC GEOGRAPHY in the 1970s. Anne Buttimer's *Values in geography* (1974), produced for the Association of American Geographers' Commission on College Geography, suggested that geographers consider the values motivating and informing their analyses: 'the present time is in many ways ripe for the expression of our caring presence to the world via an authentically lived profession of geography' (Buttimer, 1974, p. 15). Buttimer reflected upon her own values, informed by personal history, Christianity and EXISTENTIALISM, and their shaping of geography as 'one of the regions of my care' (Buttimer, 1974, p. 4). Discussion of values shaping earlier and current geographical thought, and their consequences for disciplinary identity and geography’s engagement with the wider world, followed. Buttimer asserted PHENOMENOLOGY and existentialism as approaches placing values at the centre of human experience. Responses from Blaut, Gibson, Hägerstrand and Tuan supplemented and critiqued Buttimer; in its presentation of debate, *Values in geography* offers a fine insight into questions then shaping human geography. In 1996, *Progress in HUMAN GEOGRAPHY* accorded it the status of a ‘classic’ text; Buttimer reiterated its relevance while regretting the ‘extremely anthropocentric bias in the whole discussion’ (Buttimer, 1996, p. 518). The human valuing of the non-human had, however, informed other humanistic geographies, as in Burgess and Gold's collection *Valued environments* (1982), which highlighted the human creation of worlds of meaning, whether around public symbols or fields of everyday care: ‘the close and enriching affective bond between people and the environments they create, inhabit, manipulate, conserve, visit or, even, imagine’ (ibid., pp. 4–5).

Environmental values have remained an important subject for human geography, as in recent work on ANIMALS and MORAL GEOGRAPHIES. Smith (2000a) addresses the role of intrinsic, anthropocentric and biocentric values in debates over environmental ETHICS. Harvey (1996) offers a contrasting perspective on the valuing of environment, connecting values and monetary value. Wary of conservative appeals to values as a realm of permanence and stability, Harvey seeks 'to replace the fixed idea of “values” with an understanding of “processes of valuation”' (ibid., p. 11), and pursues a DIALECTICAL understanding of values and society: ‘Values inhere in socio-spatial processes, and the struggle to change the former is simultaneously a struggle to change the latter (and vice versa)’ (ibid., p. 12). The process through which nature is valued – whether through supposedly inherent value, monetary value or METAPHOR – becomes a nexus for understanding and intervening in the relations of society and environment (ibid., ch. 7). Discussion of values is here, as elsewhere, shaped by the definition of the term employed, and must be understood in relation to the political and social imperatives shaping an author’s work.

vector data  
Vector is a primary data type encoding geographical phenomena in GIS (another is RASTER). It is based on recording point locations (zero dimensions) using x and y coordinates, stored within two columns of a database. By assigning each feature a unique ID, a RELATIONAL DATABASE can be used to link location to an attribute table describing what is found there. Line segments (one-dimensional) have two points: a start and end node. Polygons (two-dimensional) the start and end node is the same. TOPOLOGY may also be encoded. Vector objects are discrete but sometimes represent continuous fields; for example, as contours.

vertical theme  
A method of exploring change in CULTURAL LANDSCAPES by describing the processes visibly effecting that change. Attention to ‘vertical themes’ is an enduring feature in HISTORICAL GEOGRAPHY, but following the template set out by H.C. Darby the traditional approach has been to identify PROCESSES in landscape terms: thus in Darby’s (1951) essay on the changing English landscape, six vertical themes were identified: clearing the wood, draining the marsh, reclaiming the heath, the changing arable, laying out the landscape garden, and urban–industrial growth. It would be possible to identify quite other themes in altogether different terms – the transition from FEUDALISM to CAPITALISM, including ACCUMULATION by dispossession, for example, and civil war and the consolidation of the modern STATE – all of which left their marks on the landscape. But Darby was concerned to distinguish historical geography from history, and so insisted on processes that could be located directly within the LANDSCAPE. He subsequently used ‘vertical themes’ defined in less restrictive terms, but still expressed in cartographic-narrative form (diachronic analysis), to connect a series of cross-sections through the landscape at particular dates (synchronic analysis) in his New historical geography of England and Wales (1973). (See also SEQUENT OCCUPANCE.)

verticality, politics of  
A term devised by Israeli architect and analyst Eyal Weizman (2002) to describe the three-dimensional relations between POWER, SOVEREIGNTY and TERRITORY. Weizman’s argument is both general and particular. Most generally, he argues that territory must be conceptualized not as a flat MAP in two dimensions but as a three-dimensional SPACE. Sovereignty has had a vertical dimension since at least the nineteenth century through claims over subsurface RESOURCES (Braun, 2000), and since the Convention on the Regulation of Aerial Navigation (1919) individual STATES have routinely claimed complete and exclusive sovereignty over the air space above their territory. Indeed, modern WAR has come to rely on air power to such a degree that Graham (2004b) insists that the key vector of military power is now vertical and that it is necessary to formulate a ‘vertical GEOPOLITICS’.

Weizman’s core argument, however, is that these general claims have assumed a particular and intense significance during the continuing Israeli occupation of Palestinian territory. He has shown how the Israeli political strategy of colonizing the West Bank has involved extraordinary three-dimensional contortions of space to separate Israeli from Palestinian areas while maintaining Israeli control over both. Weizman emphasizes the intricate partitioning of the West Bank, the grid of Israeli colonies on the hilltops, and the network of Israeli by-pass roads, tunnels and checkpoints that work to produce ‘parallel geographies’ of First and THIRD WORLDS, ‘inhabiting two distinct planes in the startling and unexpected proximity that only the vertical dimension of the mountains can provide’.

violence  
In her essay on violence, political philosopher Hannah Arendt (1906–75) emphasizes its instrumental character. Violence appears whenever POWER is in jeopardy and ‘it always stands in need of guidance and justification through the ends it pursues’ (Arendt, 2004 [1969], p. 241). Hence, violence in and of itself stands emptied of strength and purpose: it is part of a larger matrix of socio-spatial power struggles (Kaur, 2005). Violence has been defined by the Norwegian peace researcher Johann Galtung (1969, 1990) as tripartite: (1) as direct violence, or personal injury; (2) as structural violence, where structures of social injustice violate or endanger the right to life of individuals or groups of people in a society; and (3) as cultural violence, in which any aspect of CULTURE, such as LANGUAGE,
RELIGION, IDEOLOGY, ART or cosmology, is used to legitimize direct or structural violence. In comparison to other social sciences, HUMAN GEOGRAPHY came late to theorizing violence, but Hays-Mitchell (2005) has invoked a FEMINIST analysis that draws on these diverse understandings, specifically as social, political, and economic violence.

In fact, feminist geographers have long analysed geographies of violence against women and sexual minorities, both domestic and non-domestic, as well as the built environments that engender safer spaces (Valentine, 1998; Domosh and Seager, 2001) (see FEMINIST GEOGRAPHIES). Their work has recently extended to the ways in which violence during WAR is highly gendered (Mayer, 2000; Gilles and Hyndman, 2004a). In 1996, for the first time in history, the international tribunal for war crimes in Yugoslavia prosecuted rape as a weapon of war and a crime against humanity, issuing indictments for torture and enslavement. This charge moved rape from the private realm, where it was an informal aberration of war, to a public one in which can be formally prosecuted.

Modern STATES not only claim a monopoly of the legitimate means of violence; they also routinely use the threat of violence to enforce the rule of LAW. Philosopher Giorgio Agamben (1998) outlines how the state has the capacity to make and enforce laws, but also the power to suspend them in times of emergency, thereby creating spaces of exception (see EXCEPTION, SPACE OF). Anthropologist Thomas Blom Hansen (2005, p. 111) notes that within such spaces ‘the law is identical with violence but it is a particular form of violence’. Hansen shows how SOVEREIGNTY is an unstable and precarious expression of power that requires constant repetition and performance, including the threat of violence, to maintain its legitimacy. It follows that political violence can assume many forms, and that TERRORISM – in the sense of mobilizing fear as a weapon to intimidate a civilian population – cannot sensibly be confined to the actions of non-state actors. The terrorist attacks on the USA on 11 September 2001 produced a stream of work exploring geographies of political violence by both state and non-state actors (Gregory and Pred, 2007), and it is also clear that violence, in the form of riots or protests, can be a response to state oppression (Kaur, 2005).

Economic violence has been a particular concern of MARXIST GEOGRAPHIES, where a primary focus of research is on modes of dispossession and exploitation. The process of capital ACCUMULATION has required repeated rounds of dispossession, in the past and in the present, and is written into the prospectus of NEO-LIBERALISM (Harvey, 2003b; Springer, 2008) (see COLONIALISM; IMPERIALISM; PRIMITIVE ACCUMULATION). Exploitation is also written in to the labour process and wreaks its own violence in multiple capitalist and non-capitalist forms and their articulations (see, e.g., SLAVERY). Violence is often inscribed in the LANDSCAPE, sometimes deliberately so to intimidate others, while Mitchell (2002b) argues that its aestheticization erases the conflict-laden work of its production and thus contributes to a generalized economy of violence. This is part of a wider process of the commodification of SPACE, and Blomley (2003) contends that physical violence is an intrinsic part of the foundation, legitimation and operation of Western PROPERTY regimes.

The real challenge is to trace the connections between these and other modes of violence: for violence cannot keep within the artificially produced and policed boundaries of the social, the political and the economic.
characterize the diffusion and use of computer network technologies (Dodge and Kitchin, 2001b). This work has helped to undermine the widespread myths that the Internet would lead to the ‘end of geography’ through the sheer motive force of speed-of-light interactions (Graham, 1998; see also time–space compression).

The proliferation of virtual geographies raises important questions about the relationships between electronic technologies and representations and contemporary culture. These questions are economic and political as much as they are cultural, and the same can be said of the ways in which virtual geographies bring processes of simulation and surveillance into very close interaction as embedded surveillance devices provide continuous data feeds to sustain virtual representations of the dynamics of geographical change. These developments have been particularly significant in late-modern war (Graham, 2008a,c). Consider, for example, the way in which the first 1991 Gulf War was represented through TV reportage that used digital video footage from the noses of US ‘smart’ bombs (Wark, 1994), or the way in which the US military has become deeply invested in computer simulations to recruit ‘the digital generation’ and to train troops for overseas deployment in Mission Rehearsal Exercises (Graham, 2007, 2008a,c).

Finally, this proliferation of virtual technologies blurs the boundary separating ‘real’ geographical worlds from electronically simulated and imagined ones. This occurs as participants and observers become less and less able to separate and distinguish between the ‘real’ and the ‘virtual’. As truly immersive systems proliferate, and participants increasingly adopt digitally simulated avatars and ‘bodies’ functioning ‘within’ virtual geographical space, this process seems set to intensify (Hillis, 1999). Indeed, virtual geographies are already being further complicated by the transformation of computerized network devices. These are moving from being separate artefacts such as networked PCs placed within geographical spaces, with which people interact through interfaces, and are being reinvented as small and even nano-scale constructions that blend ubiquitously and invisibly into wider geographical environments. Such trends mean that new critical approaches to virtual geographies are becoming necessary, which abandon any a priori distinction of the ‘real’ and the ‘virtual’ (see representation).

**virtual reality** Resulting partly from an ongoing challenge to the WIMP (Windows Interface, Mouse Pointer) screen that had emerged in the late 1980s, we might see virtual reality entering geography through four moments. The first moment geography encounters virtual reality is as a metaphor for the digital condition. Virtual reality is seen as expressing a symptomatic cultural desire to escape the messy, inevitable complications of the real world for an infantilized or perfected digital realm (Slouka, 1995). The second more technical moment is through the Virtual Reality Mark-up Language (VRML), which enabled three-dimensional browsing through screen interfaces. While it has not challenged the ‘page’ metaphor of the web, it has been refined into technologies to create online worlds in cyberspace. Third, this has been used to produce models and simulations of geographical locations for academic, marketing and educational purposes. Fourth, it has been part of initiatives to develop immersive environments. Here, using haptic interfaces that sense user motions and head-mounted displays, a user can interact with an entirely simulated environment all around them. While the cumbersome and faintly absurd appearance of virtual reality goggles and data gloves has limited their adoption, the technology has branched into other possibilities such as ‘augmented reality’, which attempts to ‘overlay physical objects with virtual objects in real-time and allows people to experience the virtual as if it were real’ (Galloway, 2004, p. 390).

**virus** An entity that replicates itself by infecting more complex entities and taking advantage of their reproductive systems. Biological viruses are a key agent of disease in humans and other organisms (see AIDS, epidemiology; pandemic). Computer viruses are self-replicating strands of code that ‘infect’ information systems (see internet). Usually destructive, viruses can play a creative role through their capacity to initiate connections between unrelated entities. For this reason, viruses are frequently used to figure for a view of relationality – variously termed transversal, rhizomatic or hybrid (see hybridity; rhizome) – which is presented as an alternative to linear genealogies (Ansell Pearson, 1977; Hinchliffe, 2004).

**vision and visuality** The distinction between vision – a biologically determined structure of seeing – and visuality – a culturally constructed way of seeing – has not been challenged in geographical work, despite sustained interest in embodied knowledges (see BODY; SITUATED KNOWLEDGE). Vision has been paid little attention, and questions of visuality have been most fully engaged with by cultural geographers. The starting point for much of their work is that, like any other cultural text, an image draws on particular culturally constituted signs, symbols and discourses in order to make its meaning. Images are thus understood as ensembles of visual practices that structure what is visible and invisible in specific ways. Such practices are at work in both the visual content of an image – what it shows – as well as in its visual and spatial organization – how it shows what it shows, and what position it invites its audience to take in relation to it. Much attention has been paid to how images thus constitute and reconstitute social identities and social relations by visualising, thus constitute and reconstitute social

Much attention has been paid to images as texts to be read but as objects to be put to use has also begun to discipline with a modern Western visuality dependent on the possibility of a ‘world picture’. Images produced by newer visual media, such as FILM, GEOGRAPHIC INFORMATION SYSTEMS, and tourist and family photography have also been examined as powerful means through which more recent places and spaces are constituted (see FILM; TOURISM).

While much of this work depends on claims that particular images are given their meaning by their historically and geographically specific context, or by their embeddedness in contemporary discourses (see VISUAL METHODS), Marxist strands of work also continue. Some pursue Harvey’s (1989b) claim that many visual objects reflect changes in the time–space organization of contemporary CAPITALISM, and others pursue Deutsche’s (1996b) somewhat less REDUCTIONIST account of the importance of design, ART and SPECTACLE to the capital’s redevelopment of cities (see GENTRIFICATION). It is, however, possible to suggest that most geographers concerned with visuality have been concerned to place specific images into their ‘context’, whether that context be a culture, DISCOURSE or the demands of CAPITAL. However, two other approaches to visuality are now also evident in geographical work.

First, some geographers are arguing that while certain sorts of images participate in the cultural or discursive, they can also on occasion exceed it. This claim refers to photographs quite specifically, because of the way something of what photographic technologies do is to describe the world mimetically, beyond cultural signification (see MIMESIS). Geographers such as Goin (2003) and Edensor (2005) thus insert photographs of a desert and of industrial ruins into their written text, in order to enact the intrusion of those places’ non-human, non-cultural agencies into the making of geographical knowledge. Second, others are suggesting that the effects of images can only be understood as they are encountered by viewers in particular places in quite specific ways (Rose, 2004a). This argument understands images as performed in encounters with people, and is less concerned with what images mean than with what they do and what is done with them (see PERFORMATIVITY). Hence geographers and others have explored how images are put to work in different places, and the various spaces and places that such work produces (Pinney, 2003; Rose, 2004a).

These moves (back?) towards understanding images not as texts to be read but as objects to be put to use has also begun to
change the way geographers discuss their own visualities. The complicity of academic geography with colonial ways of seeing has been clearly traced. But recent accounts of the messy process of fieldwork have emphasized the work needed to produce such authoritative ways of seeing: effort that does not always achieve its intended end (Driver, 2001b). Things in the world may remain obscure and out of focus. And even if they are visible, some theorizations of the visuality offer reminders that being visible does not always make things noticeable or knowable; both ethnomethodology and Foucauldian work suggest that noticing what is in full-view can often be extremely difficult (Laurier and Philo, 2004). Thus, as several geographers have agreed, much about the relationship between visualities and geographical knowledges still requires attention (Antipode, 2003).

Suggested reading
Antipode, (2003); Cosgrove (1985); Rose (2004); Ryan (1997).

**visual methods** The history of geographical knowledge is replete with visual images of many kinds created in order to describe particular places. Although what constituted adequate description was often debated, the recent interest in visual methods in Anglo-American geography has been prompted in part by a move away from understanding images as in some way mimetic of the world (see Vision and visuality; mimesis). Instead, it is argued that images are active participants in the construction of geographical knowledges; and it follows that to explore that participation requires some consideration of method.

There are a range of possible methods for interpreting visual materials (Banks, 2001; Rose, 2007 [2001]). The most common approach to understanding the production of visual geographical knowledges depends on making connections between a specific image already in circulation, and the wider context of which it is a part. Such approaches have included iconography – explicating the meaning of the discrete symbolic elements of an image – and semiology – treating an image or scene as a constellation of interrelated signs. Currently, however, the most common method focuses on a range of aspects of the content of an image in order to make claims about its effect in the cultural field. This has been described as a kind of discourse analysis (Rose, 2006), and is the implicit method adopted by much of the new cultural geography.

Fewer geographers have chosen to work with images produced as part of the research process. Some, however, have used images – often photographs taken by the geographer – to supplement written argument. Here, the implication is that although photographs, like any other visual image, become meaningful in relation to the wider culture of which they are a part, they also have some ability to exceed cultural meaning. They have thus been deployed by geographers with an interest in non-representational theory or material culture to suggest the agency of the more-than-human (see, e.g., Edensor, 2005).

The second way in which geographers have created images as part of the research process is by making images that exemplify or develop their analyses. Allen and Pryke (1994), for example, created montages that brought together what they saw as the different spaces of financial corporations’ headquarters that, although constitutively interrelated, were kept separate in everyday encounters. Others have systematically photographed urban environments in order to understand better the detail and texture of gentrification.

The third way in which images may be used more centrally in geographical research has been called ‘photo-elicitation’ by visual sociologists. In this approach, photographs are taken by people who the geographer has been researching for some time. The photographs are then used in further interview work, as powerful stimuli that allow the exploration of issues that might otherwise not be broached in more conventional interview situations (see, e.g., Latham, 2004).

**visualization** A means of transforming data into visual representations that, for those who work within geographic information science, takes place at the intersection of computing graphics and mathematics. Other human geographers, particularly within cultural geography, locate vision and visuality within a wider techno-cultural frame, but Kwan (2002) nonetheless claims that the intersection between computing graphics and mathematics allows more intuitive analysis and can incorporate many different agendas.

Visualization in this specific sense has its roots in early three-dimensional models in science (Watson, 1969) and in the use of computer graphics to display calculation results. But there is a much longer tradition of visual
display in pre-digital geography, from explanatory diagrams through the elaborate visual renderings of the idealized landscapes of spatial science to the three-dimensional displays of Torsten Hägerstrand’s time-geography. That spatial-graphical tradition has been re-energized through the development of Visualization in Scientific Computing (ViSC), and now increasingly incorporates relationships between conceptual and physical entities as well as three dimensions (Turk, 1994). Visualization is now widely accepted as a means of interpreting and ‘making sense’ of spatial patterns as part of a revivified cartographic imagination within these avowedly scientific streams of geographical enquiry (cf. MacEachren, 1994).

Geographic information systems can be understood as an ontology of that which can be visualized. Visualization of spatial phenomena is a delicate play between deductive and inductive techniques, a subtle shift in science that GIS promotes. Visualization provides a greater understanding, leads to effective causal variable identification and improved hypothesis formulation, and results in more reliable predictive relationships between variables (Anselin, 1988). Visualization supports a wider range of collaboration and exploration with less concern for mathematical rigour, hypotheses testing and generality (Wright, Goodchild and Proctor, 1997). Visualization is a way of making quantitative approaches less mathematical as it allows researchers to work with a large number of variables. As the number of variables increases, measures of certainty are difficult to obtain and the analysis becomes less mathematical.

Von Thünen model A model for analysing agricultural location patterns, based on the pioneering work of a Prussian landowner. Johann von Thünen (1783–1850) envisaged a single market for farm products and suggested that distance from that point would be a prime determinant of both what was produced where and the rent (net profit) generated there. Based on this variable alone, the model suggested a zonal land-use model (see figure), on the assumption that farmers produced the commodity on each tract of land that would maximize their net returns. Because of variations in the costs of transporting different agricultural products, bulkier and/or more perishable items are produced closest to the market, where land rents are consequently highest, leading to a distance-decay gradient. This ideal type arrangement—also suggested for urban areas (cf. Alonso model)—provides a model against which reality can be compared, and can be modified to take account of variations in, for example, land productivity.

The von Thünen model was a central element in the promotion of human geography as a spatial science, in the context of rational choice theory and decision-making. It was applied to land-use studies at a variety of scales (e.g. Blaikie, 1971; Peet, 1969; Block and DuPuis, 2001); Barnbrock (1974: see also Mäki, 2004) pointed out that many have been very partial in their use of von Thünen’s ideas and fail to take account of his full project, which saw his model as an ideal type of a spatial arrangement that would emerge under a benign form of capitalism. Its means of simplifying the world in order to understand it has declined in relevance as transport costs have been reduced both relatively and absolutely, but it remains a valuable analytical framework.

**War**  The mobilization of military or paramilitary violence between political communities. Although the state is often defined in terms of its claim to a monopoly on the legitimate use of physical force, war is not confined to hostilities between states: civil wars are intra-state wars, wars of liberation are fought by resistance movements against (for example) colonialism or military occupation (see occupation, military), and the global ‘war on terror’ is waged by states against regional and international terrorist organizations. Nor is war confined to formal hostilities between the main parties (‘hot wars’): the cold war between the USA and the Soviet Union took many forms, including economic warfare and numerous proxy wars.

The history of geography (see geography, history of) has frequently intersected with the history of war: war has marked the practice of geographical enquiry and geographical knowledge has shaped the prosecution of war. Classical geography knew its strategic value – Strabo’s chorography was addressed to military commanders and civil administrators in the Roman Empire – while the institutionalization of geography as a university discipline owed much to the part played by military geography in the unexpected victory of Prussia over France in 1870–1. Geography was instrumental in the development of a ‘New Army’ in Britain in the early twentieth century (Stoddart, 1992) and had a pivotal role in the formulation of modern geopolitics. Since then, geographical knowledge has been important to war in four main ways:

- **The resort to war** through the production of geo-strategic imperatives (see geopolitics).
- **The conduct of war** through the production of regional intelligence (Lacoste, 1973; Heffernan, 1996; Barnes, 2006b: see also area studies; regional geography).
- **The representation of war** through the production of imaginative geographies of ‘the enemy’ and the conduct of hostilities (O’Tuathail, 1996a; Farish, 2001).
- **The memorialization of war** through the production of symbolic landscapes (Falah, 1996; Johnson, 2003b: see also memory).

The importance of geography is not surprising, since war is fought over (and often about) territory, but new forms of war have introduced more complex concepts of space. ‘War,’ Hirst (2005, p. 151) insisted, ‘can never be de-spatialized.’

Yves Lacoste (1976) claimed that *La géographie, ça sert, d’abord, à faire la guerre* (‘Geography’s primary purpose is to make war’), and in an interview with Lacoste’s journal, philosopher Michel Foucault was prompted to trace his own spatial preoccupations to a series of martial concepts (Foucault, 1976b/1980). In a course of lectures given that same year, Foucault explored the relations between sovereign power, disciplinary power and war, tracing how the post-medieval state came to assume the monopoly of legitimate violence, expelling war to its outer limits (frontiers) while ‘secretly’ allowing war ‘to rage in all the mechanisms of power’ beneath the surface of its own juridical order. Politics was thus the continuation of war by other means. Although Carl von Clausewitz (1780–1831) would eventually propose a strategic reversal in his treatise On war (1832) – ‘War is not merely a political act but also a real political instrument, a continuation of political commerce, a carrying out of the same by other means’ – Foucault saw this as a deceptive mapping of modernity. Far from war being an interruption to the project of modernity, the last resort, the exception to be rationalized and regulated, war continues to saturate the social field; its strategies and modes of calculation are deployed to defend society (the imperative title of his lectures) against the dangers ‘that are born in and of its own body’ (Elden, 2002; Foucault, 2003: cf. governmentality). Late modern warfare is wired to political economy – to neo-liberalism and its rounds of renewed accumulation by dispossession (Roberts, Secor and Sparke, 2003; Retort, 2005: cf. resource wars) – but on Foucault’s reading it is also intimately invested in a racialized biopolitics. Both of these dimensions have been revealed with unusual clarity in the US-led ‘war on terror’ in the early twenty-first century (Dauphinee and Masters, 2007; Dillon and Reid, 2009: see also terrorism).
Some scholars have proposed the concept of a *mode of warfare* to characterize the ‘complex of social relations through which wars are prepared, military power organized and wars fought’ (Shaw, 2005, p. 42; Kaldor, 2006). Modes of warfare differ over space and time, but several writers have identified the contemporary emergence of new, global modes of warfare that are closely connected to globalization (cf. Bauman, 2001b) (see table).

On one side, and closely associated with the USA, is a *Revolution in Military Affairs* (RMA) and its successor projects, which promise that future wars can be fought with fewer ground troops through the intensive use of high technology by ever more professionalized and specialized armies. New systems of sensing and surveillance from air and space platforms, advanced systems of information management (‘command, control and communications’ or C3), and weapons systems revolving around pilotless aircraft and robotic vehicles, precision-guided weapons and ‘smart bombs’, substantially rework the spatial templates of geopolitics. Crucially, the significance of physical distance is diminished though not erased: the distance over which air strikes can be launched is increased, but the global deployment of ground forces and equipment still poses logistical problems (Ek, 2000; Graham, 2008b; Singer, 2009). These developments have produced a convergence between military operations and the advanced sectors of the global economy, particularly the armaments, telecommunications and software industries, and the connections within the Military–Industrial–Media–Entertainment complex have been reinforced through the enhanced *time–space compression* made possible by *network-centric warfare*. This transforms the battle space from the conventional, linear form with its geometry of fronts and battles, advances and retreats; instead, military forces ‘swarm’ in complex, fluid formations through multiple theatres of war that ‘will be as virtual as they will be geographic, coursing through the capillaries and conduits that comprise networksociety itself’ (Dillon, 2002, p. 74). The combined effect of these innovations is to institute a hypermodern form of warfare that creates what Coker (2004) calls a ‘re-enchantment’ of war: offensive, ‘surgical’ strikes target combatants and supposedly minimize ‘collateral damage’, death virtually disappears from the battle space, and military interventions are increasingly staged as *just wars*.

On the other side are so-called *new wars* fought by non-state and para-state actors including militias and guerrilla forces who, when they engage professional armies, resort to *asymmetric warfare*. For the most part these armed groups rely on local, ground-based knowledge and the use of cheap, light and even improvised weapons (Kaldor, 2006). Although their violence is close-range and even face-to-face, these conflicts often spill across *borders*. Combatants take advantage of border zones, such as the tribal territories straddling the Afghanistan–Pakistan border, but their activities are also enmeshed in what Nordstrom (2004) identifies as an even wider ‘shadow globalization’: many of the armed groups are supported and funded (at least in part) by emigré communities; they draw their

recruits from diasporic populations, from refugee camps and from city-dwellers who have been forcefully excluded from the global economy; and they are involved in trans-local networks that are non-state, non-formal and extra-legal, and which in many cases traffic not only in weapons but in conflict commodities such as drugs and diamonds. Münkler (2005, pp. 2, 36) represents these developments as in some measure a throwback to the Thirty Years War (1618–48) and, in contrast to hypermodern forms of warfare, they create a rhetorical ‘disenchantment’ of war: they are extraordinarily savage and intensely corporeal, they deliberately target non-combatants, and they sustain an economy of lawless predation (see Gregory, 2009b).

These two modalities of war converged with extraordinary intensity in the early twenty-first century in the military operations undertaken by the USA and its allies in Afghanistan and Iraq and by Israel in southern Lebanon and occupied Palestine, where the advanced weapons systems of state militaries were met by crude missiles, improvised explosive devices, suicide bombs and guerrilla raids (Gregory, 2004b, 2006). Indeed, the two modalities have increasingly bled into each other: the US invasion of Afghanistan involved a high-tech war from the air in support of a ground war fought by US troops in close concert with the local militias of the Northern Alliance, for example, while the US occupation of Iraq prompted the US military to perform a ‘cultural turn’ that accorded local knowledge a central place within a counter-insurgency campaign that could not be waged through firepower alone (Gregory, 2008, 2009a). Critics have often claimed that American military power has been deployed in the service of a new American empire, and Münkler (2005) argues that these ‘new wars’ characteristically develop ‘in the margins and breaches of former empires’. But the two modalities of war also increasingly converge in cities. According to Davis (2004b, p. 15), ‘the poor peripheries of developing cities will be the permanent battlefields of the twenty-first century’, and urban warfare is an increasing preoccupation of military strategists (Graham, 2009a).

These two modalities of contemporary war have several mutually reinforcing effects:

- **They blur the distinctions between war and peace**: many of these conflicts are chronic with no clearly defined beginning or end, characterized by ‘peace processes’ rather than peace agreements.

- **They blur the distinctions between war and commerce**: the US military is not only closely connected to the global arms industry, but it also relies on private service companies and contractors, and militia leaders and warlords often have a keen interest in the profits of war.

- **They blur the distinctions between civilian and combatant**: they make it difficult to distinguish civilian and military spaces; conflicts increasingly spill across and in some places even constitute the spaces of everyday life; and in many, perhaps most cases the majority of casualties are civilians (Giles and Hyndman, 2004b). Militias are often criticized for their indifference to civilian casualties, but Shaw (2005, pp. 71–97) insists that the RMA also involves the systematic transfer of risk to civilians whose deaths are explained away through either their own alleged complicity or accidental, ‘collateral damage’ (see also Gregory, 2006a).

- **They blur the distinctions between the real and the virtual**: late modern targeting and imaging systems radically transform the visual field of war, and professional armies are acutely sensitive to the effect of media images; militias are also keenly aware of the power of video coverage, and the ‘war on terror’ has involved the conscious deployment of spectacle and the mobilization of affect on both sides (Ó Tuathail, 2003; Retort, 2005; Gregory, 2006).

Even as the two modalities become entangled in one another, the distinctions between them have been rhetorically reaffirmed to produce an imaginative geography that is also a moral geography: thus ‘our’ wars are construed as humane wars because they are fought within the space of the modern – the space of reason, science and law – whereas ‘their’ wars are inhumane because they are located outside that space. Dexter (2007, 2008) argues that this de-politicizes late-modern war – ‘Western intervention is elevated to a position above politics’ – and de-legitimizes all forms of warfare except those of the global north, which then has both the obligation and the right to police the frontier between the two in the name of security. **water** A prerequisite for life on Earth, water, unlike some ‘natural’ resources, has no substitute. It is present at every scale, from the global atmospheric system to the individual
cell, and stores, redistributes and releases about 30 per cent of the total amount of solar energy that hits the Earth (Clarke, 1993). To some extent a renewable resource, water’s availability is nevertheless finite and dependent on regional variations, seasonal fluctuations and CLIMATE change, as well as being subject to sustained, and sometimes violent, local and GEOPOLITICAL disputes.

Water resources are powerfully shaped by human actions, including reduction of the Earth’s storage capacity through development of the built environment (e.g. in the suburban expansion of major cities around the world); the degradation of water quality through POLLUTION (e.g. in the arsenic poisoning of groundwater wells in Bangladesh and West Bengal); and the overuse or mismanagement of water resources that makes them scarce (e.g. in the 1930s Dust Bowl in the Great Plains of the USA). Water has also attracted monumental feats of civil engineering and technological governance throughout human history, and has been frequently tied up with the constitution of NATION-STATES and national identities (see NATIONALISM). The mega-dams that became emblems of the assertion of independence of sovereign states (re)-emerging from the yoke of European IMPERIALISM in the second half of the twentieth century are one example. Another is the long history of sustained engineering that has gone, and continues to go, into stabilizing the low-lying territory of the Netherlands (Bijker, 2005).

Human geographers have made important contributions to understanding the material cultures and political economies of water use over a long period, through various theoretical perspectives. Amongst the most significant of these perspectives are ENVIRONMENTAL HISTORIES of the politics of water GOVERNANCE in situations of water scarcity and conflicting demand, such as in California (see Gottlieb and Fitzsimmons, 1991), and the constitutive role of water in the POLITICAL ECOLOGY of world cities such as New York (Gandy, 2002).

**welfare geography** An approach to geography where the emphasis is on SPATIAL INEQUALITY and TERRITORIAL JUSTICE. Bound up with the rise of RADICAL GEOGRAPHY in the early 1970s, welfare geography stresses the need to identify and explain the existence of CRIME, hunger, POVERTY and other forms of discrimination and disadvantage. Originally conceived by David Smith (1977), welfare geography basically sought to reveal who gets what, where and how. This early work was largely descriptive, and developed the abstract formulation used in welfare economics, grounding it empirically but maintaining the use of algebraic representations. It provided a basis for evaluation. Current welfare configurations, in terms of who gets what, where and how, could be judged against alternatives. This preoccupation with description eventually was matched, and then superseded, by work on the processes through which inequality is produced. MARXIST ECONOMICS replaced NEO-CLASSICAL ECONOMICS as the basis for explanatory analysis, which takes place at two different levels. The first involves understanding how the whole economic–political–social system functions, and teasing out generic tendencies (see MODE OF PRODUCTION). In the case of CAPITALISM, for example, this level of analysis reveals that inequality is endemic. UNEVEN DEVELOPMENT is the spatial imprint, the geographical result of the restlessness of capitalism as a system. The second level of explanation attends to the details of particular economic–political–social systems; for example, how housing policy under capitalism advantages some people in some places and disadvantages other people in other places. The analysis of the politics behind these policies has recently been reinvigorated (Staeheli and Brown, 2003), as part of renewed interest in the relationship between SOCIAL JUSTICE and the STATE. Accompanying an attention to the restructuring of the WELFARE STATE, which characterizes much of this recent work (Peck, 2001b), have been efforts to theorize a relational ETHICS of care. Drawing on FEMINIST theory, this work seeks to uncover the social relations behind constructions of care and of justice. Understanding politics as integral in the everyday doing of care, the emphasis is on the connections and relations rather than the difference between categories, such as private and public, state and MARKET (Smith and Lee, 2004).

**Suggested reading**
Smith and Lee (2004); Staeheli and Brown (2003).

**welfare state** A social system whereby the STATE assumes primary, but not exclusive, responsibility for the welfare of its citizens – more specifically, those parts of the STATE APPARATUS involved in the direct provision or management of public services and benefits. In principle, the welfare state exists to address issues of SPATIAL INEQUALITY and TERRITORIAL JUSTICE through income and wealth redistribution policies. In areas of
policy such as education, employment, health, social services and transport, the state apparatus strives to ensure the delivery of some basic levels of service. So, for example, state-funded schooling sets out to ensure that every child receives an education. Empirical studies have, however, revealed that in practice it is not easy to control who benefits. They have found that it is sometimes the case that the most affluent in society who gain from the provision of public services.

The modern Western welfare state emerged during the 1930s and 1940s, in the context of the two world wars and significant economic and political turbulence. The precise timing differed from one country to another, as did the functions that were brought within the remit of the welfare state. Most noticeably, for example, the USA has never had a national health service, unlike most of the nations of Europe. In general, welfare states were formed to address some of the fundamental social issues of the time, such as disease, inequality and poverty. A strong role for the state apparatus was created, in which it would ensure a basic standard for all citizens. These decisions reflected the wider belief at the time in the fundamental right to education, employment, health care, and social services. Rules by which the welfare state might continue to deliver the services, the conditions under which this is performed has been restructured both quantitatively and qualitatively (Pierson, 1991). Although in many countries it remains heavily involved in the lives of citizens, its size and its organization have changed considerably in recent years. Critiques from the political parties of the right have become mainstream policy in a number of countries. In a growing number of countries, we have witnessed a significant rethinking of the role assigned to the welfare state. On the one hand, some functions it previously performed have been contracted-out to private-sector providers, in the form of privatization, or through the formation of public-private partnerships. This growth in private-sector firms, employing their workers on private-sector terms and conditions, troubles the notion of public services (Pinch, 1997). How public is a service managed by the welfare state but delivered by the private sector, according to market rules? This also challenges us to reflect carefully on where the welfare state starts and stops, where its edges are (Peck, 2001a). On the other hand, the introduction into the state apparatus of private sector-type audits, evaluations, management techniques and performance indicators has transformed its modus operandi. While the welfare state might continue to deliver the services, the conditions under which this is performed is as a result qualitatively different (Jessop, 2002).

**West, the** The idea of the West and the concept of westernization are interwoven with a world-view that believes in the superiority of the human over the non-human, the masculine over the feminine, the adult over the child, and the modern over the traditional. Legitimized through ‘anthropocentric doctrines of secular salvation, in the ideologies of progress, normality and hyper-masculinity, and in theories of cumulative growth of science and technology’ (Nandy, 1997, p. 169), westernization is akin to another form of colonization — an intimate enemy — which at least six generations of the Third World have learnt to view as a prerequisite for their liberation. This colonialism colonizes minds in addition to bodies and it releases forces within the colonial societies to alter their cultural priorities once and for all. In the process, it helps generalize the concept of the modern West from a geographical and temporal entity to a psychological category. The West is now everywhere, within the West and outside; in structures and in minds. (Nandy, 1997, p. 170)

For Bhabha (1985), such omnipresence of the West (cf. eurocentrism) allows opportunities for hybridity and resistance: when colonized people become ‘European’, the resemblance can subvert the identity of that which is being represented. The hybrid that articulates colonial and native knowledges may reverse the process of domination as repressed knowledges enter subliminally, enabling subversion, intervention and resistance (Peet and Watts, 1993).

The concept of development, with its close affinity with teleological views of history, science and progress, has served as a central and dynamic theme in Western modernist discursive formations. By the end of the nineteenth century, both the colonialist as well as the radical alternative intellectual traditions became associated with ‘linearity, scientism, and modernization, universalisms which carried the appeal of secular utopias constructed with rationality and enlightenment’ (Peet and Watts, 1993, p. 232). With capitalism, bureaucracy and science as the holy trinity,
development became MODERNITY on a planetary scale, in which the West served as the ‘transcendental pivot of analytical reflection’ (Slater, 1992, p. 312). Western modernity attempted to organize social life on the basis of voluntary actions of individuals whose values were supposed to be predominantly UTILITARIAN. Similarly, NATURAL RESOURCES came to mean those parts of NATURE that were required as inputs for industrial production and colonial TRADE. Technology and economics mutually reinforced the assumption that nature’s limits must be broken for the creation of abundance. The concept of the NATION-STATE, moreover, displaced other surviving notions of the STATE, the latter being perceived as examples of medievalism and PRIMITIVISM (Anderson, 1991 [1983]). The process was strengthened when ‘indigenous’ intellectuals and activists confronting the colonial power found in the idea of the nation-state the clue to the West’s economic success and political dominance:

Indeed, no other idea, except probably the twin notions of modern science and development, was accepted so uncritically by the elites of old continuous civilizations like China and India. Even modern science and development became, for Third World elites the responsibility precisely of the nation-state and two new rationalizations for its predominant role. (Nandy, 1992, p. 267)

Development discourses have continued to construct the relationship between West and non-West in terms of the West being the detached centre of rationality and intelligence: the West possesses the expertise, technology and management skills that the non-West is lacking. Conversely, this lack is the chief cause of the problems of the non-West (cf. OCCIDENTALISM; ORIENTALISM). What is consistently ignored in this framework are questions of power and inequality, whether on the global level of international MARKETS, state subsidies and the arms trade, or the more local level of landholding, FOOD supplies and income distribution. This dominant paradigm of the West, furthermore, ‘constitutes a perfectly auto-referential sphere, containing only a very limited number of elements. Need, scarcity, work, production, income, and consumption are the key concepts within an enclosed semantic field that has no need of the outside world’ (Latouche, 1992, p. 254).

While the history of the ‘modernizing’ world is often erroneously written as one of failed imitation of the West – failures of secular DEMOCRACY, NATIONALISM, enlightened modernity or enslavement to ‘tradition’ – scholars working in the post-colonial paradigms have complicated such frameworks (see POST-COLONIALISM). Conceptualizing modernity as a construct and an organizing trope, especially for the national developmentalist successors of colonial regimes, these scholars have suggested ways in which the complexities of the East–West encounters might be better apprehended through METAPHORS of translation, hybridization and dislocation, rather than more monolithic ideas of imitation, ASSIMILATION or rejection (Abu-Lughod, 1998, p. 18). Furthermore, they have complicated the very exercise of knowledge production ‘in and for the West’ where the very act of writing for the West about ‘the other’ implicates us in projects that establish Western authority and cultural difference (Abu-Lughod, 2001, p. 105).

Such intellectual projects acquire particular significance in the context of FEMINIST politics in the THIRD WORLD, which has had to negotiate a complex relationship with Marxist struggles at home, as well as with women’s movements and writings in the West (Loomba, 1998, p. 253: see also MARXISM). Despite the deep scepticism to which ‘feminism’ and agendas associated with Western feminisms are often subjected in post-colonial contexts, women’s movements have consistently challenged the assumption that women’s activism in post-colonial worlds are only inspired by their Western counterparts (see FEMINIST GEOGRAPHIES). Such moves have involved rewriting indigenous histories, appropriating pre-colonial symbols and mythologies, and amplifying the voices of women themselves, each of which is ridden with its own problems and contradictions (Loomba, 1998). Grappling with ‘the woman question’ anywhere requires: (a) attending to the complex ways in which the West and things/concepts associated with the West are embraced, repudiated and translated in contemporary politics; and (b) developing subtle ways of thinking about the CULTURAL POLITICS of past and present colonial encounters, and more broadly, the relationship between the constructs of East and West as they have shaped anti-colonial nationalist projects on the one hand, and the complex dynamics between processes of GLOBALIZATION and the post-colonial nation-state on the other (Abu-Lughod, 1998).

wetlands Covering about 6 per cent of the Earth’s land area (Turner, 1991), wetlands
WHITENESS

include rivers, lakes, marshes, fens and peatlands, and intertidal and shallow-marine environments up (such as salt marshes and mangroves). Wetlands are economically important as sources of fish, crops, grazing land and other products, and provide critical ecosystem services (World Resource Institute, 2005). Key threats include dams, pollution, introduced species, aquaculture, agriculture, urbanization and industrialization. The 1971 Ramsar Convention promotes the conservation and ‘wise use’ of wetlands as a contribution to achieving sustainable development. There are over 1500 Wetlands of International Importance, covering (129 million hectares) (http://www.ramsar.org/).

whiteness A racialized identity that is bound up with power and privilege (see also race; racialization). Although whiteness is a long-established part of a geographical imagination, it has only been subject to critical scrutiny in recent years, particularly since the 1990s. Both within and beyond geography, the power and privilege associated with whiteness has underpinned its normalization and assumed transparency, against which other racialized identities are perceived as visible, different and/or inferior. But since the 1990s, geographers and others working across the humanities and social sciences have interrogated whiteness, white identities, and their normative and naturalizing power (for an influential study, see Dyer, 1997). Rather than view whiteness as a fixed and essentialist category, geographers and others have traced more complex and differentiated racializations that are bound up with class, ethnicity, gender and sexuality, as shown by research on ‘poor whites’ in the USA and South Africa; whiteness, mixed descent and racial ‘passing’; the gendered and sexualized commodification of whiteness; and the ways in which the racializations of the white working class and the Irish, for example, complicate assumptions about white privilege. Geographers have explored the power relations of whiteness and white identities in relation to racist and anti-racist politics; their spatial and temporal differentiation; and their articulation within and through both the disciplinary spaces of geography and other spaces such as the street, suburb, town, city and nation (see, e.g., Bonnett, 2000; McGuinness, 2002).

Both the normative power of whiteness and critical studies of whiteness have their own geographies. The emergence of ‘White Studies’ in the late 1990s brought together critical work across a wide range of disciplines, and has been largely based in the USA (including Delgado and Stefancic, 1997). Other researchers have sought to widen comparative and transnational research beyond what might be termed ‘American whiteness studies’ (Ware and Back, 2002, p. 14) by studying the power relations and material effects of whiteness in a wide range of different contexts. In his forceful critique of multicultural Australia, for example, Ghassan Hage (1998) analyses the ways in which ‘fantasies of White supremacy’ have shaped ideas about the nation. He considers ‘“Whiteness” to be itself a fantasy position of cultural dominance born out of the history of European expansion’ (p. 20). Alastair Bonnett (2000) analyses the ‘mythologies of European whiteness’ in relation to two, connected processes: first, ‘The development of non-European (and non-racialised) white identities and their marginalisation or erasure by an increasingly hegemonic, European-identified, racialised whiteness’ (p. 7); and, second, the ways in which ‘the development of whiteness as a racialised, fetishised and exclusively European attribute produced a contradictory, crisis-prone, identity’ (p. 8). Unlike work that not only overlooks the importance of white identities beyond the particularity of European and/or Western modernity, but also fails to interrogate this particularity, Bonnett (2000) has studied whiteness and the meaning of modernity in Latin America and Japan.

Like other research that recognizes the social construction of ‘race’ and ethnicity, the critical study of whiteness in both historical and contemporary contexts has been concerned with the risks of reifying whiteness and its normative power. As Vron Ware and Les Back explain, ‘For us it is impossible to separate the act of writing about whiteness from a political project that involves not simply the fight against racism, but also an attack on the very notion of race and the obstinate resilience of racial identities – one of its most disastrous consequences’ (2002, p. 2).

wilderness A condition, usually applied to a landscape, of being wild, out of human control, uncultivated and uninhabited. Wilderness is a highly contentious term with a long history of usage. As an uninhabited land, wilderness has had both negative and positive value. Until the late eighteenth century, Euro-Americans
regarded wilderness as unproductive, as wasteland, full of danger, a place to be crossed without delay. It was also land ripe for domestication, for bringing into the house of human and godly order. The gendering of such landscapes (the fertile though poorly harnessed feminine wilds, set against the progressive and ordered masculine settlement) is another element to this entrenched cartography of nature or culture. The dualism is carried forward, rather than being overturned, by more contemporary environmentalist interest in wilderness as a refuge from the ravages of modern industrial and urban society. The valorization is reversed and wilderness becomes something to save. Particularly evident in the national parks movement in North America, and later in Africa and Australasia, conservationists have sought to protect wilderness from human incursion, producing a form of fortress conservation (Adams and Mulligan, 2003). Such enclosures are highly controversial, particularly since the advent of a series of critiques of the idea of wilderness, specifically the sense that current understandings of wilderness tend to be rooted in Western value systems and fail to adequately understand the complexities of landscape histories and geographies. The environmental historian William Cronon produced one of the more telling critiques, arguing that current concerns over biodiversity and endangered species continue the wilderness tradition, producing a deep fascination for remote and exotic ecosystems (the classic example being the tropical rainforest) (Cronon, 1996). As Cronon went on to suggest, protecting the forests often involved protecting them from the people who lived there (and were in fact partly responsible for the existing ecologies). The cultural myth and ecological imperialism of a peopleless nature resulted in forced removals akin in historical and ecological terms to the tragedy that befell the American Indians. Historical, geographical and post-colonial imaginations have started to displace wilderness, demonstrating its peculiar heritage and power as an idea, and the material consequences of emptying wild places of people. In addition, there has been work that has sought to demonstrate the material and social connections between so-called wilderness and so-called civilisation, particularly through figures such as wild animals which, it turns out, exist within and across a complex web of spaces, neither confined to wilderness nor ever reduced to civilizing processes (Whatmore, 2002a). The result of this work is certainly fraught by the realization that environmentalism has a good deal invested in pure categories such as wilderness. Practical manifestations such as fortress conservation are certainly not criticized across the board, even while the complexities and paradoxes of such practices are recognized (Adams and Mulligan, 2003). Meanwhile, the power of the idea is evident in its longevity and cross-cultural currency. The polarization of the civil and the wild is not confined to Western cultures. While the dynamics can be different, the place of wilderness as other to (or distance from) society often seems to be populated in different ways and at different times where it forms part of a spatial practice or rite of passage. From the recuperative desert of the Old and New Testaments, to male circumcision rituals, to contemporary safaris and gap-year treks (see also tourism), wilderness acts as a complex repository of values.

world city A major node in the organization of the world-economy. The term was originally coined by Geddes (1915) to denote those ‘great cities in which a quite disproportionate part of the world’s business is conducted’. But contemporary usages owe much more to Friedmann’s much later (1986, 1996) discussions of world cities as global control centres, which gave the term both a theoretical and an analytical inflection. Those conceptual elaborations, in concert with world-systems analysis, have inspired a major programme of research into globalization and world cities. Friedmann’s much later (1986, 1996) discussions of world cities as global control centres, which gave the term both a theoretical and an analytical inflection. Those conceptual elaborations, in concert with world-systems analysis, have inspired a major programme of research into globalization and world cities. At Loughborough University in the UK. In fact, the intimacy of the connections between ‘world cities’ and globalization have prompted many researchers to substitute the term ‘global city’.

World Social Forum (WSF) First convened in January 2001 in Porto Alegre, Brazil, the World Social Forum is an annual meeting held by members of the so-called anti-globalization movements – sometimes dubbed the ‘movement of movements’ (Mertes, 2004) – to provide a setting in which global and national campaigns can be coordinated, shared and refined. It is not an organization or a united front, but ‘an open meeting place for reflective thinking, democratic debate . . . by groups
and movements of civil society that are opposed to neo-liberalism and to domination of the world by any capital or any form of imperialism’ (see www.wsf.org). The WSF has grown substantially from its first meeting in Brazil. Subsequent meetings in 2002 and 2003 were also held in Porto Alegre, and thereafter in Mumbai (2004), Porto Alegre (2005) and Nairobi (2007). In 2006 a ‘poly-centric forum’ was held in Bamako (Mali), Caracas (Venezuela) and Karachi (Pakistan). In 2001, 12,000 people attended the WSF; by 2007 the number had grown to 60,000 registered attendees, and 1,400 organizations representing 110 countries. The WSF has also prompted the establishment of a number of regional fora – the Asian Social Forum, the Mediterranean Social Forum, and in 2007 the first US Social Forum – though not all of them stand in a similar relation to the ‘parent body’.

The genealogy of the WSF is complex. The fact that four of the WSF meetings have been held in Porto Alegre – a city with strong connections to the Brazilian Left and the Workers Party, and the home to an innovative model of local government and participatory democracy (so-called participatory budgeting) – says much about the broad ideological thrust of the Forum. It stands ideologically against neoliberalism and free market capitalism; it is of the Left but it looks for new and different models of economic and political organization, drawing from a vast array of experiments embracing the landless workers movements, anti-dam struggles, indigenous peoples, and anti-corporate and multilateral struggles. The idea of a global convention of anti-capitalist movements was in part driven by the desire to provide a counterweight to the World Economic Forum held every year in Davos, and by the difficulty of organizing mass protest in Switzerland capable of generating sufficient media coverage to challenge the prevailing hegemony of free market discourse and practice. The protests against the World Bank and International Monetary Fund annual meetings in 1999 and thereafter – most notably in Seattle, Genoa and Washington, DC – were an important milestone in the move towards an alternative forum for civic movements opposing unfettered capitalism around the world.

It is impossible, however, to understand the WSF outside of the counter-revolution in development thinking and, relatedly, the growing dominance of neo-liberalism (free markets, free trade, privatization and state cutbacks). The abandonment of Keynesian models of capitalist development – marked by the ascendancy of Ronald Reagan, Margaret Thatcher and Helmut Kohl – and the rapid adoption of the economic ideas associated with Friedrich von Hayek and Milton Friedman and the Mont Pelerin Society, had massive and direct implications for the global south, beginning in the 1980s with the massive onslaught of structural adjustment and stabilization programmes. It was out of this combination of ‘economic reform’ (namely, the rapid liberalization of state-led development), ‘shock therapy’ and in many places massive economic recession (e.g. the early 1980s and the late 1990s) that the plethora of movements, often arraigned against the privatizations of various commons (see primitive accumulation) arose. In contradiction to the triumphalism (and purported inevitability) of globalization that dominated the 1990s, the WSF stood for, in their own language, ‘another world is possible’ rather than ‘there is no alternative’. In some circles, the WSF is held up as a shining example of what Hardt and Negri (2004) call ‘the multitude’.

Inevitably, a forum embracing a massive heterogeneity of movements from around the world must confront the problem of political coherence and its strategic role. The WSF has 14 principles (laid out in Porto Alegre in 2001) as part of its Charter. These include strong statements against ‘totalitarian’ approaches to economy, politics and development, and a robust critique of corporate capitalist and global regulatory institutions such as the World Trade Organization and the IBRD. But in practice the WSF has never functioned as a central or strategic decision-making body, and has often run aground on the reefs of political diversity. Popular movements often stand very differently in relationship to development than, for example, nongovernmental organizations (NGOs), and there are no procedures as such for adopting consensus statements or advocacies. As it has grown in size and scope – and become something of a media event for visible anti-globalization celebrities (Tariq Ali, Vandana Shiva) – the early radicalism of the first forum has been lost and dissipated.

World Trade Organization (WTO) Although the idea of an international trade organization was formulated in 1944 at Bretton Woods, today’s World Trade Organization was only
founded in 1994 at the close of the Uruguay Round (1986–94) of the General Agreement on Tariffs and Trade (GATT) talks in Marrakesh. Its purpose is to liberalize international trade by enforcing free trade rules, arbitrating international trade disputes, and working to forge new global agreements on the removal of tariff and so-called non-tariff barriers to trade (the latter including all sorts of national rules on health and environmental protections). Unlike the International Monetary Fund (IMF) and the World Bank — which were set up at Bretton Woods to run on a ‘one dollar, one vote’ principle — the WTO operates on an ostensibly more inclusive model, in which the voices of individual member states are all meant to count. However, because the ground rules for inclusion are fixed as free trade rules, because the basic goal of the organization is to remove frictions on the movement of commodities, and because the organization’s disputes resolution mechanism works on the assumption that it is intrinsically good to reduce both tariff and non-tariff barriers to trade, the WTO serves institutionally to expand and entrench neoliber alism on a global scale (Peet, 2003; see also terms of trade). Everywhere its rules apply, the WTO enables the privatization of formerly public goods and common property resources, whether they be medicines, government-provided health services, shared forests or clean water. As well as thereby facilitating accumulation by dispossession (Harvey, 2005: see primitive accumulation), WTO rules also simultaneously undercut democratic governance insofar as they provide a powerful lever through which businesses can reduce or eliminate democratic law-making (including, for example, legislation banning carcinogenic chemicals and pesticides) by coding the resulting public interest laws as non-tariff barriers to trade (Wallach and Woodall, 2004). Another neo-liberal aspect of the WTO is that there is no possibility under its free trade rules to permit development strategies that are not neo-liberal, such as state assistance to new industries, that try to establish themselves in the face of competition from developed producers elsewhere. As a result, the WTO has been criticized for ‘kicking away the ladder’ (Chang, 2002) for the world’s poorer countries, preventing them from following a path once taken by countries such as the USA and Japan that used industrial protectionism in their early approach to development. It has been this basic injustice, combined with the WTO’s democracy-eroding complicity in processes of dispossession, that has led so many critics to take to the streets from Seattle in 1999 through to Hong Kong in 2006. Ironically, however, it has been yet another injustice noted by the protestors that has ultimately proved most damaging to the WTO’s own attempts to expand free trade since the ‘Battle in Seattle’. This injustice is the disproportionate power still wielded by the US government in negotiations because of the importance of the US market in global trade. The irony is that because the USA has been unwilling to fully implement free trade itself, and, most notably, because (like the EU) it has been unwilling to give up the huge subsidies given each year to domestic farmers, US officials have been moving increasingly away from the multilateralism of WTO negotiations, where they face growing demands from developing countries to eliminate such practices. As a result, American trade negotiators have preferred more recently to develop bilateral trade deals with particular countries such as Singapore, and, meanwhile, the WTO’s failing attempts to expand free trade remain an important reminder that globalization is not so inevitable after all.

world-systems analysis A materialist and historical approach to the study of social change developed by Immanuel Wallerstein (1979, 1984, 1991a). The approach builds upon three research schools — dependency theory, the annales school and marxism (see historical materialism) — to create a unidisciplinary and holistic historical social science. The approach was integral to the reinvigoration of political geography in the 1980s and its usage in geography is still largely restricted to this sub-discipline (Flint and Shelley, 1996).

World-systems analysis runs counter to mainstream social science in its definition of society. Wallerstein begins by identifying three basic modes of production, or ways of organizing production and social reproduction. The reciprocal-lineage mode describes a society in which production is organized around age and gender differences and exchanges are reciprocated within the group. The redistributive-tributary mode occurs in class-based societies in which a large class of agricultural workers gives the surplus of their production to elites. The capitalist mode of production is also class based, but is defined by ceaseless capital accumulation motivated by the market which sets prices through the logic of supply and demand.

Wallerstein defines society by the spatial extent of these modes of production, and not
necessarily by political borders. Hence, three types of society are identified: mini-systems are small tribal entities following the reciprocal-lineage mode; world-empires, such as the Roman empire or feudal Europe, practice the redistributive-tributary mode; and world-economies are capitalist. In the broad historical purview of world systems, the contemporary capitalist world economy emerged in Europe in the fifteenth century and has since diffused to encompass the whole globe and eliminate all other forms of society. Thus, the modern world system is a single society, the global capitalist world-economy. Scholars have used world-systems analysis to study all types of society, but geographers have concentrated upon the modern world-system (Flint and Shelley, 1996).

The geographical expression of political borders and the spatial extent of society were matched in mini-systems and world-empires. However, in the capitalist world-economy the mode of production is defined by a global market, while the system is divided into separate states. It is here that Wallerstein’s challenge to mainstream social science lies. He claims that social scientists equate states with society, and therefore have only a limited view of social change if they restrict analysis of cause and effect to one country. The result is the error of developmentalism (Taylor, 1989), practiced within both liberal and Marxist social science, arguing that countries move through particular stages of development; for example, individual countries were identified as ‘progressing’ through stages of population dynamics following the demographic transition model. Alternatively, social change occurs at the scale of the system, and changes within states occur within the broader context. Such thinking led to critique of world-systems analysis as denying the agency of states and other groups.

Geographers have attempted to address this critique through an application of geographical scale (Taylor, 1981). Taylor identified three key political scales; the locality, the nation-state and the global. Ultimately, processes of social change can be traced to the global scale, but individual agency occurs at the local scale within the political and social limits set by states, themselves restricted by the imperatives of the global scale. Such an approach has been critiqued as structurally deterministic, but others have shown how political agency is limited within the constraints of the modern world-system (Flint, 2001).

Initially, geographers complemented their application of geographical scale with a focus upon a key feature of the modern world-system, the core–periphery hierarchy. The capitalist world-economy is necessarily unequal, comprised of peripheral processes (low-income and low-profit production) and core processes (high-income and high-profit). These processes cluster geographically, so that core processes may dominate (but not exclusively) in some states, and vice versa. In the UK, for example, core processes predominate, but some expression of peripheral processes is also evident in inner-city sweatshops. In addition, some states and regions are identified as semi-peripheral – with a relatively even balance of core and periphery processes. Core and peripheral processes were used to map broad global geographies of equality (Flint and Shelley, 1996).

Recent analysis by political geographers has focused upon two concepts; hegemony and world cities. A hegemonic power is the one dominant state in the modern world-system. Its power rests upon economic strength, but is also expressed in the dissemination of culture (Taylor, 1999). The ‘war on terror’ has been identified as the geopolitical response of the USA, the current hegemonic power, in the face of violent challenge (Flint and Falah, 2004: see terrorism; war). World cities have been identified as the key nodes on a new geographical expression of power in the modern world-system, a network of economic and cultural relations that facilitates capital accumulation (Knox and Taylor, 1995). Mapping the goods and services produced within particular cities and their interconnectivity results in a hierarchy of cities, and informs geographies of sovereignty and globalization.

World-systems analysis challenged liberal and Marxist approaches to social science, and has been critiqued by both – by one for being too structural and Marxist and by the other by not being these things enough! Wallerstein (1991b) has also challenged the way in which social science is organized into separate disciplines. Instead, world-systems analysis is a unidisciplinary approach, encompassing economic, political, social, and cultural processes to show how culture and politics are inseparable from economics. Although world-systems analysis was at the forefront of the revitalized political geography, it is no longer dominant, however, and instead is now one of many theories informing the sub-discipline.

zonal model  A model of intra-urban spatial organization created by E.W. Burgess (1886–1966: see Burgess, 1924), a leading member of the 1920s CHICAGO SCHOOL of sociologists. To assist in understanding why certain types of social problem were concentrated in particular areas, he split an idealized city (based on Chicago) into five zones (see figure), whose dominant feature is the increase in an area’s socio-economic status with distance from the CBD (‘The Loop’ in Chicago). Growth was propelled outwards from that point by INVASION AND SUCCESSION processes involving new immigrants to the city, who established homes in the ‘zone in transition’ and pressed longer-established groups to move towards the SUBURBS and beyond. Burgess’ model was complemented by Hoyt’s SECTORAL MODEL and combined with it to form a MULTIPLE NUCLEI MODEL in work on urban residential patterns. (cf. FACTORIAL ECOLOGY; SOCIAL AREA ANALYSIS).
ZONE OF DEPENDENCE

Suggested reading
Johnston (1971).

zone of dependence  An area characterized by the spatial clustering of residential and other facilities used by those dependent on the state and other bodies (such as charities) for housing and other support. The importance of such facilities has been increased with the general trend involving the closure of many psychiatric and other facilities and replacing them with ‘community care’, with many of its facilities located in the inner city, where large properties are available for conversion and there is less likelihood of resistance from established residents (cf. NIMBY). That spatial concentration encourages their users to find accommodation nearby, thereby creating an area where such dependent people, many suffering in various ways from social exclusion, dominate. As more people congregate in such zones, more facilities are placed there to serve them, and eventually a situation akin to the creation of a ghetto emerges.  RJ

Dear and Wolch (1993).

zoning  A term used to describe the practice of dividing a city or region into tracts of land, or zones, for the purposes of land-use planning. Each zone is assigned a set of permitted uses (e.g. residential, commercial, industrial or some subdivision of these, such as single-family residential), often overlayed by regulations on density, height and design. Regulations are codified in a comprehensive plan and, consequently, shape future urban development (Smith, 1983). The character of zoning regulations varies greatly among countries, with some framing them at the national level and others – particularly the USA – having a localized and fragmented system. This local ability to use state power to advance the general good over individual interests is based on US Supreme Court decisions – such as the famous Village of Euclid v. Ambler Realty Co. of 1926 – which established the right of cities to limit the uses to which private property owners could put their land.

While zoning is, in one sense, a mundane bureaucratic practice, its history and present operation are also tied up with wider social questions. For example, ethnic discrimination forms the basis for early zoning regulations in North American cities. Worries among white elites about the encroachment of ‘undesirable’ ethnic groups such as Chinese populations led to ordinances that only permitted their businesses, such as laundries, in specific areas. Today, exclusionary zoning continues to be used, often by wealthy municipalities, to exclude low-income people. Strategies of exclusion include requirements that houses be built on large (i.e. expensive) lots and prohibitions on apartment buildings.

Proponents of contemporary zoning argue that it provides a transparent framework for decision-making, since principles of development have been codified before decisions on particular proposals are made; that it provides predictability for landowners, investors and developers; and that it offers safeguards for residents and the environment by controlling the spread of unwanted or noxious land uses. Critics point to zoning’s unequal effects and its potential for discriminatory social exclusion; criticize its restrictions on landowners; point to its tendency to produce large, environmentally damaging land-use monocultures, such as single-family suburban subdivisions; and worry about the potential for zoning decisions – particularly those regarding requests to change existing zoning or to seek an exception (a variance) – to be unfairly influenced by interest groups.

Contemporary urban policy concerns, including the mitigation of urban sprawl and the encouragement of compact and mixed-use developments, relate to zoning. Growth management and smart growth strategies, such as growth boundaries (beyond which, the types of permissible urban land uses are strictly regulated) are used to maintain compact cities (Knaap and Nelson, 1992). Within cities, long-standing criticisms of single-use zoning and developers’ interest in mixed use developments have led to the increased use of zoning categories that accommodate a variety of land uses in one location (Knox, 1991).

Finally, it is worth noting that zoning is frequently the object and stake of urban politics. Developers and landowners often lobby for changes in zoning to increase the value of their holdings (a tract may be more valuable if its zoning is changed from industrial to residential, for instance). Environmentalists or neighbourhood activists often oppose such changes when they seem to create negative externalities (McCann, 2002).  EM

zoos  Enclosures where animals are held for a variety of purposes, including display,
human entertainment and education, *ex situ* breeding and conservation. Initially developed from menageries of animal exotica, and designed for human consumption, zoos responded in the mid-to-late twentieth century to public anxiety, animal welfare and environmental criticisms by re-staging and re-selling animal collections as crucial to biodiversity conservation (Anderson, 1995). Zoos then formed networks linked by the movements of animals, reproductive tissues and records (Whatmore, 2002a). Animal lives were behaviourally enhanced, and collections shifted from the comprehensive (displaying a wide variety of specimen species) to the specialized (focused on sustainable groups of species types). Criticisms remain, especially from those who regard zoo improvements as little other than conscience and market protection devices in an increasingly competitive edu-tainment sector.

Index

Note: This index aims to provide a guide to the complex interconnections within human geography. References to particular topics will be found most easily by looking up that particular topic, but extensive sets of subheadings also indicate the various aspects of more general headings. In addition, a network of see and see also references indicates alternative headings and related topics. Alphabetical arrangement is word-by-word. References to particular authors are included only where their work is quoted or discussed in some detail. Page numbers in bold type indicate the main discussion of a topic that is also treated in less detail on the other pages cited. Page numbers in italics refer to diagrams.
